The pathology of pelvic inflammation is settled beyond cavil. Non-puerperal pelvic inflammation is peritonitis, non-puerperal pelvic cellulitis does not exist, or exists only as a curiosity—resulting from traumatism and infection of the pelvic connective tissue. These statements are also nearly true of puerperal pelvic inflammation. Puerperal peritonitis is common; puerperal cellulitis is rare. It is also equally well known that pelvic peritonitis almost invariably means salpingitis with infection of the peritoneum by discharge of the tubal contents at the fimbriated end of the tube; and that recurring attacks of pelvic peritonitis are due to leaky tubes. Other causes of pelvic peritonitis are changes taking place in pelvic tumors, especially dermoid cysts, traumatism and perhaps the effect of exposure at the menstrual periods. These facts have been known for thirty years, having been discovered by Bernutz, and they have been demonstrated fully by the surgery of to-day.

It is also equally well known that chronic pelvic peritonitis does not tend to a natural cure, and that recurrences of acute peritonitis are characteristic of the disease, being due to leakage from the focus of poison, the diseased tubes. The natural end of such cases is invalidism or death during a recurrent acute peritonitis. Experience has shown that medical treatment, while affording much palliative benefit, is inadequate to effect a cure. Ablation of the diseased uterine appendage or appendages, the focus of the disease, is the only treatment offering a radical cure. When operation is done early, before the patient is a wreck, the immediate risk to life is slight, less than five per cent., and prompt restoration to health follows. Operations done on such diseased structures does not in any way lessen the fecundity of women; they are sterile by reason of the disease. It restores such sufferers to health and usefulness; saving some from invalidism and others from death. These facts are now amply demonstrated and are opposed only by those in the profession who object to exerything which has not the stamp of antiquity upon it.

What, then, becomes the duty of the practitioner when called to attend these cases? To recommend operation by skilful hands. No more pressing duty devolves upon him, and it is time that the matter is brought home to the practitioner. He should know and feel that he is neglecting his duty when he puts such cases to bed, treats the acute attacks by opium internally and poultices externally; and between attacks paints the vagina with iodine and inserts the glycerin tampon. Such neglected cases are brought later to the surgeon either as broken-down wrecks, or as women dying with suppurative peritonitis. These are the "too late" cases. Either their nutrition is so profoundly depraved that they require months to recu-

perate, or being past recuperation they remain wrecks, or swell the death-list of the surgeon who is too conscientious to refuse them a last chance. Hereafter the responsibility for such maltreatment will rest with the family physician.

The cases in which hesitancy may be felt are cases of slight or catarrhal salpingitis, in which the fimbriæ are not agglutinated, and in which accumulation of tubal secretions has not occurred. These cases are subjects for watchful care. Such of them as progress from bad to worse may be referred to the surgeon. The others are fair subjects for medical treatment, so long as life is threatened by attacks of peritonitis.

THE TONGUE IN SCARLET FEVER.

Authorities differ as to the constancy and diagnostic significance of the appearance of the tongue in scarlet fever. Upon the suggestion of Prof. Fürbringer, Dr. Neumann made a series of observations on the tongue in forty-eight cases of scarlet fever at the Friedrichshain Hospital, at Berlin, and records in the *Deutsches Archiv für Klinische Medicin*, January, 1891, the results of his investigation.

The changes in the tongue presented themselves in three stages. In the first, the mucous membrane became swollen, and the tongue was enlarged and corrugated on its surface, while the epithelium became cloudy. The tongue also presented the appearance of being heavily coated, except at the tip and margins. In the second stage, desquamation took place. This was most marked at the surface of the fungiform papillæ, and gave rise to the characteristic appearance of the strawberry tongue. In the last stage restoration of the epithelium took place, at times with such rapidity as to cause the tongue to again appear coated. Naturally, deviations from this typical course occurred. These could be explained by antecedent or complicating conditions.

The characteristic appearances of the tongue presented themselves in thirty-eight of the forty-eight cases, carefully inspected at intervals of two or three days—that is, in seventy-nine per cent. In six cases, no appreciable changes occurred. In five of these there had been digestive derangement or septic intoxication; while in the remaining one no complicating condition could be discovered.

In the majority of the cases, desquamation took place from the third to the fifth day of the disease and left for more than four days longer the strawberry tongue which, in twelve cases, was still present on the fourteenth day. Thus in a third of the cases, the strawberry tongue disappeared during the first week; in another third, during the second week; while in the remaining third it was still present at the end of the second week. There was no relation observed between the intensity of the changes in the tongue and those in the skin.

From the foregoing, it may be concluded that the appearances of the tongue in scarlet fever constitute a characteristic, though not a constant feature of the disease.

EPILEPSY AND ALYLENE HYDRATE.

Notwithstanding the fact that many remedies have been from time to time brought forward for the treatment of epilepsy, the bromides yet remain the most trustworthy and most effective at our command. There are, however, certain cases in which the bromides absolutely fail to render any service, or in which for one reason or another they are not well borne. For these cases, it would be desirable to have a remedy that could at least be used to alternate with, if not as a substitute for, the bromides. Stimulated by the results recorded by Wildermuth, in the *Neurologisches Centralblatt*, No. 15, 1889, from the use of amylene hydrate in the treatment of epilepsy, especially when the attacks were frequent, Dr. Richard Drews, of Altona, determined to try the remedy in just such a case, and in the *Mün-*

chener medicinische Wochenschrift, January 27, 1891, he reports the disappointing and unfavorable results he obtained. The case was a typical one of epilepsy, in a woman thirty-five years old, without other neurotic history, in whom the attacks had begun at twenty years of age, and had continued with gradually increasing frequency. Bromides and chloral had been used without avail. Finally, resort was had to amylene hydrate, twenty-five grains three times a day. The attacks increased in frequency, one following each administration of the remedy, the appetite failed and there was severe headache and sleeplessness.

In view of this experience it seems as if amylene hydrate was of little use and that the bromides are yet the best remedy in the treatment of epilepsy. Perhaps too much disappointment should not be felt, and experimentation with amylene hydrate should not be wholly abandoned, because it may be suited to some cases, if not to others; but the experience of Drews certainly tends to dampen the ardor caused by Wildermuth's reports.

MEDICAL AND SURGICAL COLLEGE OF NEW JERSEY.

In the REPORTER for January 10, 1891, we called attention to resolutions in regard to the so-called Medical and Surgical College of New Jersey, adopted by the Hudson County Medical Society, and referred also to the exposure of the methods of this College made in the REPORTER as long ago as August 24, 1889. It is pleasant now to be able to report that—largely through the efforts of the State Board of Medical Examiners of New Jersey—the charter of the institution mentioned has been repealed by the Legislature, and the repealing act has been approved by Governor Abbett.

We heartily congratulate the New Jersey Board of Medical Examiners upon this fruit of its labors so soon after it came into existence. The institution just abolished was largely made up of electics, who, so far as we can tell, have somewhat different standards of professional and general excellence from those which prevail in the regular profession.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

DISEASES OF THE EYE. By EDWARD NETTLESHIP, F. R. C. S., Ophthalmic Surgeon to St. Thomas's Hospital, etc. Fourth American from the Fifth English Edition. 12mo, pp. 500. 164 illustrations. Philadephia. Lea Brothers & Co.

This excellent manual, designed as an introduction to the study of eye-disease, seemed at its first appearance the most concise, direct and practical presentation of the subject to be found in the English language. Each edition has showed distinct improvement, and the present gives evidence that the revisions have been careful as well as numerous. Much that at first seemed merely implied and to be read between the lines, but only by one already familiar with the subject, is now clearly and explicitly stated; and, while brevity gives a dogmatic character to many of the opinions set forth, there is only gain to the learner in this. He is not left halting between two opinions; and he can accept, as well-grounded, every view of this careful, experienced and conservative author. A few errors have escaped elimination in the revision, and a few statements are open to criticism. Thus under "optical conditions of clear sight," p. 40, it is stated that an object must subtend an angle of 5 minutes, in order that its form may be perceived. This is true of square letters like Snellen's, as stated on p. 48; but does not hold for simpler forms. Objects and spaces of 1 minute ought to be distinguished in good in-door light. In the designation of prisms the numbering by the actual deviation produced seems to be ascribed to Maddox, instead of to Jackson; and no mention is made of the metric designations of Dennett and Prentice, which complete the reform which ought to be made. The "pseudo-coloboma" of the iris may be upward or in any direction; so the statement is incomplete that coloboma "is always downwards." The table of prisma ic effect of decentering lenses quoted from Maddox, notes on spring catarrh, pemphigus of the conjunctiva, corneal transplantation, etc., bring the work up to date; and by the substitution of new cuts and in its general typography this edition seems an improvement on the last. On the whole, this book may be said to fully deserve the warm welcome which it has already received, and to be worthy of hearty recommendation to the profession.

ÉTUDES SUR LA RAGE, ET LA METHODE PASTEUR. PAR LE DR. LUTAUD, Rédacteur en Chef du *Journal de Médicine de Paris*. 2d Edition. 12mo, pp. x, 440. Paris. *Journal de Médicine de Paris*, 1891.

This second edition of Dr. Lutaud's book on hydrophobia comes at an interesting time, when he finds himself engaged in combating the extravagances of the claims of Koch's followers. The extremes to which Pasteur and his disciples have pushed his notions in regard to the so-called protective inoculations against rabies, have found a curious counterpart beyond the Rhine, and as Pasteur's claims found little

recognition there, so in turn have the claims of Koch been coldly received in France. It may be yet that Lutaud will devote himself to collating the failures and fallacies of the Koch method, as in the book before us he collates the failures and fallacies of Pasteur's method. One who reads this book will see in it, however, intimations of something worse than failure and fallacy—that Pasteur has been guilty of misrepresentation, and has made the discoveries which were exploited as humane and scientific, the means of acquiring wealth as well as universal fame. It will be seen here, likewise, that nothing, against which Pasteur has proposed a sure preventive, has been prevented, and that the diseases of the vines, the diseases of the silk-worms, the diseases of the dogs, the diseases of cattle still ravage France and other lands formerly exposed to them; and he who looks for success in connection with Pasteur's brilliant claims will find them principally in the fortune which he has amassed and the reputation which he has secured. In this there is no claim that Pasteur has not been industrious and ingenious, and from the scientific standpoint a very useful investigator; but it appears that whenever he has passed from the field of the investigator and has attempted to make any practical application of his theories, the result has been more brilliant than lasting, and is likely to serve rather as a warning than as an example.

SUGGESTIONS TO THE MEDICAL WITNESS. By J. S. Wight, M. D., Professor of Operative and Clinical Surgery at the Long Island College Hospital, Brooklyn, N. Y. 12mo, pp. 228. Cambridge: Printed at the Riverside Press. 1891.

Dr. Wight has written a very readable book on a very important subject. It is so common now for medical men to be summoned as expert witnesses that it is as important for them to be as well prepared for the trying duties of the situation as possible. Unfortunately many medical witnesses go on the stand without any previous experience, and with no better preparation than a desire to do justice and bear true witness. While this is the most important prerequisite, of course, for good testimony, it is, nevertheless, a fact that the position is often trying because of its mere novelty, and more often trying because of the harrassment of the witness by the attorneys. To be forewarned in regard to the difficulties of the situation would be, in many cases, to be forearmed; and the recorded experience and opinions of a man like Prof. Wight cannot fail to be helpful.

Literary Notes.

—P. Blackiston, Son & Co. announce for early publication, "*A Handbook of Local Therapeutics*," being a practical description of all those agents used in the local treatment of disease, such as Ointments, Plasters, Powders, Lotions, Inhalations, Suppositories, Bougies, Tampons, etc., and the proper methods of preparing and applying them.

The diseases which chiefly require local treatment are those of the Respiratory Passages, Ear, Eye, Skin, together with certain general surgical affections, including the Diseases of Women. In order, therefore, that the various uses of each remedy may be thoroughly set forth the following gentlemen have assumed the authorship: Harrison Allen, M. D., Emeritus Professor of Physiology in the University of Penna.; Laryngologist to the Rush Hospital for Consumption; late Surgeon to the Philadelphia and St. Joseph's Hospitals. George C. Harlan, M. D., late Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine; Surgeon to the Will's Eye Hospital, and Eye and Ear Department of the Pennsylvania Hospital. Charles B. Penrose, M. D., Surgeon to the German Hospital; Instructor in Clinical Surgery, University of Pennsylvania, and Arthur Van Harlingen, M. D., Professor of Diseases of the Skin in the Philadelphia Polyclinic and College for Graduates in Medicine; late Clinical Lecturer on Dermatology in Jefferson Medical College; Dermatologist to the Howard Hospital.

Each remedy will be taken up in alphabetical order, and after a succinct description of their pharmaceutical properties, by Dr. George I. McKelway, will be considered with reference to the local treatment of the affections above outlined. The authors believe that the information contained in this work will not be found elsewhere. The activity in the various lines of special medicine is one of the most striking phases of the times, and has materially changed many of the older methods of treating disease by local means. The greater part of the literature which has appeared is not accessible to most physicians. The *Handbook*, it is believed, will be of value to general practitioners as well as to those who, like themselves, are especially interested in sub-divisions of the clinical field.

The work will form a compact volume of about 400 pages, arranged in a manner to facilitate reference and containing, besides the usual index, a complete index of diseases, that will greatly enhance its usefulness.

—A few months ago the *Home-Maker* underwent changes which improved its appearance and intrinsic value very materially. The number for March, 1891, is a very good specimen of the American monthly magazine. It is well printed on handsome paper, and fully illustrated, largely by means of process pictures. It contains articles of great interest, among which may be mentioned, "Sheep in California," the "Study of American Republics" and one on the "Burrows of the Prairie Dog." This magazine is edited by the well-known writer, "Jennie June," and contains considerable matter especially interesting to women. The subscription price, $2.00, is so moderate that it ought to have a large circulation.

Notes and Comments.

American Academy of Medicine.

The Sixteenth Annual Meeting of the American Academy of Medicine will be held at Washington, D. C., May 2–4, opening at 3 P. M., May 2.

As it is just previous to the Sessions of the American Medical Association, members will be able to attend both meetings.

Hiccough Cured with Nitrate of Amyl.

Last February a young woman of Shelton, Connecticut, had a prolonged attack of hiccough which seriously imperilled her life, despite the physician's efforts. In conse-

quence of the circulation given the case in the newspapers, remedies were sent from all parts of the country. Many were tried, and that suggested by Frank W. Mack, of the Associated Press, New York, was effective. The remedy was nitrite of amyl, a few drops to be inhaled from a handkerchief. On February 10, it was announced that the young woman was out of danger.

Simple Treatment of Ingrown Toenail.

The *Pittsburgh Medical Review*, February, 1891, cites Dr. Puerckhauer (from the *Münchener med. Wochenshrift*) as recommending a simple, and at the same time competent treatment for ingrown toe-nail.

A forty per cent. solution of potassa is applied warm to the portion of the nail to be removed. After a few seconds the uppermost layer of the nail will be so soft that it can be scraped off with a piece of sharp-edged glass; the next layer is then moistened with the same solution, and scraped off; this must be repeated until the remaining portion is as a thin sheet of paper, when it is seized with a pincette and lifted from the underlying soft parts and severed from the other half. The operation does not require more than half an hour's time, is painless and bloodless, while the patient is delivered from his suffering without being disabled even for an hour.

Dietetic Employment of Fat.

W. Zuntz has a paper on the dietetic employment of fat in the *Therapeutische Monatshefte*, October, 1890. He was induced to put to the experimental test of some conditions of digestion of fat, a preparation of chocolate suggested by von Mering. The chocolate is so made that it possesses a sufficient quantity of free fatty acids to form a permanent emulsion, without in any way injuring the taste of the chocolate. In order to find out whether the digestibility of fat is enhanced by the power to form an emulsion, Zuntz sought to find out what quantity of cacao butter, with and without the addition of fatty acids, was appropriated when administered to dogs. The result was, that there was an increase in digestibility, which was only slight—two per thousand of the fat—if moderate quantities of cacao butter were cooked with the rest of the food, but it was considerable if (as is usually the case with cod-liver oil, in order to avoid stomach digestion) the cacao butter was given some time before the rest of the food and in somewhat greater quantities. In the latter case, there appeared in the stool 9.9 per cent. of pure cacao butter, and only 6.1 per cent. of the emulsionized.

Corresponding to the result of the emulsionizable cacao butter in dogs, the fat of Mering's chocolate proved to be very digestible in men. For three days a moderate diet poor in fat, consisting of bread and lean meat, was given, and, in addition, a daily quantity of 416 grams of chocolate containing 87 grams of fat. In the feces appeared only 4.88 per cent. of fat; whereas Weigmann, in a series of experiments with ordinary cacao butter, administering 53 grams, recovered 5.5 per cent. In comparison with the most used fats, and those fats prized on account of their being easily digestible, such as butter, lard, marrow, the fat of the chocolate preparation is seen to be considerably superior.—*Deutsche med. Wochenschrift*, Jan. 1, 1891.

Treatment of Stricture of the Ileo-cæcal Valve.

In the *Bulletin Médical*, December 31, 1890, Prof. Péan has a lecture on the treatment of strictures of the ileo-cæcal valve, in which we are glad to see that he is acquainted with Philadelphia work in this field, Barton's cases being referred to in some detail. Péan's operation consists in exposing by an incision the ileum at its junction with the cæcum, and occluding the bowel both above and below the valve with rubber tubes fastened with forceps. The tubes serve the double purpose of preventing hemorrhage and keeping fecal matter from circulating in the intermediate portion of bowel during the operation. The intestinal wall is then incised longitudinally over the valve for a distance of three and one-fourth inches. After washing the interior of the bowel with a one per cent. solution of carbolic acid, the condition of the valve is examined. If it is found transformed into fibrous tissue, and so retracted as to occlude the bowel, it is resected down to the muscular coat of the bowel. This done, the two extremities of the intestinal wound are brought together in such a way that the ileum and cæcum

are brought together. The opening in the bowel thus becomes lozenge-shaped instead of longitudinal, the two upper sides being formed by the ileum and the two lower by the cæcum; the sides are then approximated with the forceps, and are united so that the line of suture is transverse to the bowel. Péan thinks this method of operating possesses a number of advantages, especially as it establishes an ampullar dilatation at a point where before there was stricture.

Jefferson College's New Surgeon.

At a meeting of the faculty of Jefferson Medical College on March 9, Dr. H. Augustus Wilson was elected Lecturer on Orthopedics in the Jefferson Medical College and surgeon in charge of the Orthopedic Department of Jefferson Medical College Hospital, to succeed Dr. O. H. Allis, resigned. Dr. Wilson is Professor of General and Orthopedic Surgery in the Philadelphia Polyclinic and College for Graduates in Medicine, Lecturer on Orthopedic Surgery in the Woman's Medical College. The present success of the Polyclinic is due largely to his industry and enterprise, and his present appointment is probably a tribute to these same qualities.

The Law of Periodical Function in Women.

Probably no single function of the human organism has called forth so many hypotheses as the menstrual loss of blood, occurring in healthy women at regular intervals. Though many ingenious explanations have been proposed, none is entirely satisfactory. In the *Wiener medizinische Presse*, February 8, 1891, v. Ott reports observations, not exclusively upon menstruation, but upon the various vital processes occurring in women during the period of generative activity. These processes correspond in time to the hemorrhage, are associated conditions, with a dependent relation to it. Observations upon temperature, pulse and blood pressure indicated that vital activity attained its maximum preceding the menstrual period and declined at its commencement or immediately before. Sphygmographic tracings, muscle strength, and excretion of urea suffer similar variations. Observations were made at a certain hour each morning during prolonged periods, sometimes extending into the menstrual periods, upon heat radiation, muscle strength, pulmonary capacity, inspiratory and expiratory force, the tendon reflexes, in healthy women placed under the same condition; and a physiological functional periodicity of the female organism was demonstrated. To establish the connection between menstruation and this periodicity of function, it is necessary to determine if the rhythmical variations are independent of menstruation. A large number of observations made by Dr. Schichareff, under the guidance of von Ott, upon pulse, temperature and blood pressure, in girls between the ages of eight and thirteen years, and in women between the ages of fifty-eight and eighty years, showed that no such periodical variations of physiological functions occur in females during the periods in which they are not capable of conceiving, and in which they do not menstruate.

Teeth in Diabetes.

The importance of early diagnosis in diabetes cannot be over-estimated, because the prognosis may be much influenced by the institution of early treatment. It is interesting, therefore, to call attention to the fact that the *Wiener medizinische Presse*, January 4, 1891, contains a brief abstract of a publication by Magitot in *Bulletin médical*, in which he dwells upon the diagnostic significance of alveolar osteo-periostitis as a manifestation of diabetes. He has noticed, in this disease, a deviation of the tooth, which, later, becomes loosened. At the same time an alveolar catarrh exists. Ultimately the tooth falls out. In the further course of the disease, the alveolar border of the bone may be absorbed, and this in turn may be followed by gangrene of the gum.

Druggist's Error in Germany.

The *Chemist and Druggist*, January 31, 1891, says: A singular case in connection with a mistake in dispensing is now occupying the attention of the Berlin authorities. Some time ago a prescription was presented to the assistant at a Spandau pharmacy ordering a draught composed of sodii nitrat., potas. bromid., aq. dest., and syr. mannæ, for a child. The assistant by mistake dispensed spirit of camphor instead of the distilled water, but the error was discovered after the administration of the first dose to

the patient, and no ill results followed. But the father thought he would try to make some capital out of the mistake, and threatened the pharmacist with exposure, demanding first 3,000 marks as hush money, and, when that was refused, dropping his price for secrecy to 140 marks. But the chemist declined to compromise, and the father wrote about the mistake to the local press. The police got wind of the affair, and they are now killing two birds with one stone. The chemist's assistant was prosecuted for causing bodily injury through carelessness, and fined 50 marks, and the would-be blackmailer is being dealt with for the more serious offense of trying to commit illegal extortion by threats.

Congress of American Physicians and Surgeons.

Congress of American physicians and surgeons will hold its second triennial meeting in Washington, D. C., September 23–25, 1891, under the presidency of Dr. S. Weir Mitchell, of Philadelphia. The vice-presidents, *ex-offico*, are: The president of the American Surgical Association, Dr. Claudius H. Mastin, of Mobile, Ala.; the president of the American Ophthalmological Society, Dr. Hasket Derby, of Boston; the president of the American Otological Society, Dr. Gorham Bacon, of New York; the president of the American Neurological Association, Dr. Wharton Sinkler, of Philadelphia; the president of the American Gynæcological Society, Dr. A. Reeves Jackson, of Chicago; the president of the American Dermatological Association, Dr. Francis B. Greenough, of Boston; the president of the American Laryngological Association, Dr. William C. Glasgow, of St. Louis; the president of the American Climatological Association, Dr. Frederick I. Knight, of Boston; the president of the Association of American physicians, Dr. William Pepper, of Philadelphia; the president of the American Association of Andrology and Syphilology, Dr. Fessenden N. Otis, of New York; the president of the American Orthopædic Associatian, Dr. Newton M. Shaffer, of New York; and the president of the American Physiological Society, Dr. Henry P. Bowditch, of Boston. The chairman of the Executive Committee is Dr. William Pepper, of Philadelphia. The treasurer is Dr. John S. Billings, of the army. The secretary is Dr. William H. Carmalt, of New Haven. The subjects for report and discussion mentioned in the preliminary programme are as follows.

Tuesday, September 22, 3 P. M.—Conditions underlying the Infection of Wounds, including a discussion of Disinfection with Reference to the Treatment of Wounds, of the Relation of Bacteria to Suppuration, of the Resistance of Tissues to the Multiplication of Bacteria, and of the Effects of Antiseptic Agents on Wounds. Referee, Dr. William H. Welch, of Baltimore; co-referee, Dr. Roswell Park, of Buffalo. The discussion will be adjourned if necessary until Friday afternoon.

Wednesday, September 23, 3 P. M.—The Late Manifestations of Syphilis. Referee, Dr. Phineas S. Conner, of Cincinnati; co-referee, Dr. Abner Post, of Boston.

Wednesday evening.—The president's address, to be followed by a reception.

Thursday, September 24, 3 P. M.—Fibroid Processes (Chronic Interstitial Inflammation, Scleroses); their Pathology and Ætiology, with Special Reference to the Influence of Diathesis and Heredity. Referee, Dr. Alfred L. Loomis, of New York; co-referee, Dr. William Osler, of Baltimore.

Friday, September 25, 3 P. M.—If necessary, the discussion on The Conditions underlying the Infection of Wounds, etc., will be resumed.

Is Sterility a Disease?

The Medical Press, February 25, 1891, says: A civil record has recently been tried in Dublin before Mr. Justice Holmes and a jury in which an enunciation of the law was made by the judge which is of much importance to the profession, and which raises very interesting considerations. The suit was instituted by a Dublin physician to recover fees to the amount of 19 guineas for attendance upon the wife of a solicitor. The lady, it appeared, suffered from no other disease save sterility, but anxiously desired a cure for this condition and sought advice with this object, whether with or without the knowledge and consent of her husband was not clearly proved. The physician attended and made many examinations by speculum and sundry applications of sponge tents and other instruments for the purpose of dilating the cervix uteri. The lady's husband refused to pay on the ground that the treatment of his wife for the

cure of sterility was not a "necessary" for which the law required him to pay, and on the additional ground that the physician's attendance took place without his knowledge or consent, but this latter plea may be taken as formal. The law laid down by Mr. Justice Holmes in his charge to the jury, which we regret to say has not been reported in the newspapers, is as follows: 1. Every man is bound to provide necessary medical care for his wife in case of sickness. 2. Every husband is liable for payment of fees in case of such sickness, whether he knows of the attendance on his wife or not; but, 3, Sterility is not a sickness for the treatment of which a husband can be made liable. It does not shorten life, nor prevent the carrying out of household duties, nor cause physical pain. Therefore medical attendance for the remedy of such condition is not a "necessary" within the meaning of the law, and the physician, in this suit, was unable to recover the fees due to him. It should be added, however, that he could still recover against the separate estate of the wife, if she had any, for "work and labor done" though the "work and labor" might not be legally "necessary," as against the husband. This decision raises a distinction between a sickness and an abnormal condition which we have not seen previously defined in a court of law, and it is interesting to consider how far the definition extends. For instance is a nævus, or a wart on the back, such a condition as the law would consider to require "necessary" attendance? None of these shorten life, none of them prevent the carrying out of domestic duties, and none of them cause physical pain, and yet they have always been considered as subjects for medical and surgical treatment, but, if the dictum of the learned judge in this case is to be trusted, of which we have no doubt, practitioners will find it necessary, in future, to secure themselves in such cases, by a definite contract with the husband before they enter upon attendance of the wife.

Infusion of Roses for Diarrhœa.

Dr. A. V. Alexeevski (*Bolnitchnaia Gazeta Botkina*, December, 1890) says that preparations of rose petals have usually been used only as vehicles, but never as an independent medicament. He found the infusion of flores rosarum an excellent therapeutic agent, especially in diarrhœa. Only chronic cases were chosen, which did not yield to any ordinary treatment known for diarrhœa. The infusion was prepared by putting a handful of the dried leaves in a glassful of hot water and keeping the mixture covered in a warm place for about two hours. To adults from two to three glassfuls of the infusion were given; to children a glassful in divided doses during the day. The best results were obtained from flores rosæ rubiæ; the infusion of flores rosæ centifoliæ was found weaker in its action. It is better not to add any sugar to the infusion as it only gives the infusion an unpleasant taste.

Three chronic cases are stated to have been permanently benefited by the above treatment. One patient was a middle-aged woman, and two were children of three and a half and two years old respectively.

The beneficial action of the infusion is due, first, to the presence of tannin, and second to the volatile oils, oleum rosarum being one of them. The latter possesses antiputrifactive and anti-fermentative properties. The preparation of the red rose is recommended to be used for children.

Primary Pyemia.

Primary pyemia, *i. e.*, pyemia without any apparent focus for the primary supply of infectious matter to the general system, is very rare. Dr. L. P. Alesandroff, in the *Bolnitchnaia Gazeta Botkina*, October 17 and 24, 1890, relates the history of an interesting case of this form of pyemia in a young boy who was under his charge.

The boy was ten years old, with a negative family and personal history. December 2, 1890, he fell on the floor and hit his knee slightly. It did not give him any pain, even immediately after the fall. December 4, he began to complain of slight pain in his knee and general malaise. He had no special treatment until December 6, when high fever was discovered, after which he was sent to the hospital. On admission the child was found in a condition of septicemia. The leg and foot on the side of the injury presented all the signs of acute infectious osteomyelitis, for which Alesandroff immediately performed an operation. On the following day the patient was very restless, began to fail rapidly, and died in the night.

The *post-mortem* examination disclosed old

pleuritic adhesions, hemorrhagic faci in the lungs and in the cardiac pericardium, changed in some places into pus, purulent arthritis, limited osteo-myelitis and purulent cellulitis in the leg. All the appearances were those of acute and recent disease, and it appeared impossible to regard any of the pathological points as the original source through which systemic infection had taken place.

Alesandroff says that the general septic condition developed entirely independently of the slight injury received to the joint. He supposes that, in this case, a number of germs found their way into the system, and having met with little or no resistance of the tissues caused the general blood poisoning. Falls and injuries in children are an every-day occurrence, and he thinks that, in similar cases, it is not justifiable to look upon a slight fall or injury as being the cause of acute septicemia. He refers to a similar case reported by Prof. Kohts, in the *Deutsche Medicinische Wochensch.*, 1887.

Another such case is reported by Dr. R. R. Ball, in the *New York Medical Journal*, February 14, 1891, under the heading "Case of fatal septicemia following contused injury to the thumb in a strumous subject."

An Appliance to Facilitate the Insertion of the Soft-Rubber (Nelaton's) Stomach-Tube.

Dr. Gustave Liebmann, Attending Physician to Patients with Stomach Diseases, North End Dispensary, Boston, says, in the *Boston Medical and Surgical Journal*, March 5, 1891: In the every-day use of a stomach-tube the soft elastic (Nelaton's) tube is by general agreement the one to be preferred. Although the hard gum tubes enter the pharynx and œsophagus much more readily, they are at any rate relegated to the rarer cases of poisoning with suicidal intent, where, from obvious reasons, the application of a soft tube is not feasible. In all applications of a tube for diagnostic or therapeutic purposes we use the soft kind, as it is well-nigh impossible to do any mischief with them, and they "sit" much easier in the stomach, giving rise to less irritation or gagging than a hard tube. Still the introduction of a soft tube is at times, although generally not difficult, a source of great annoyance to both physician and patient. And why? Because for the passage of the instrument from the fauces to the beginning of the œsophagus we have to depend on the intelligence and docility of the patient. He has to swallow the tube and work it through the pharynx, and only then are we enabled to push it down to the cardiac orifice. Should the patient from some cause (awkwardness, nervousness, and so on), fail to swallow, as it happens in some exceptional cases, then we are helpless and have to give up the job. Now to overcome this difficulty I have during the last three months used a simple appliance, that served me exceedingly well.

Although I designed the stylet and had it made to suit my fancy, I must state that the conception of it I got from a lady patient, returning from Professor Leube, in Wurtzburg, who told me that the doctor used some sort of a staff to steady the tube. The stylet is made of rattan, is about thirty-four inches in length, to fit that of the ordinary Nelaton, and to project besides one and a half to two inches at the proximal end, is well smoothed down, of the thickness of a No. 6–8 English catheter (according to the caliber of the tube), with one end curved like the beak of a metallic bougie, but of uniform thickness from one end to the other.

The curved end of the well-lubricated stylet is inserted and pushed forward through the tube, until it arrives at the distal end of the latter, care being taken that no part of it protrudes through any one of the openings at the end of the tube. It is advisable to bend tube and stylet still more into the requisite curve before inserting in the fauces. This done, the tube, with the stylet sticking out at the proximal end, is cautiously inserted—like any other hard-gum tube—into the fauces and pushed forward along the pharynx to a point corresponding with the lower border of the cricoid cartilage, or in other words, to the beginning of the œsophagus, when the stylet is withdrawn, and the tube slid down to the cardiac orifice without any further trouble. You see the soft tube is changed into a stiff one but for the short minute during which it has to pass the pharynx; we remove the stylet, and have to deal with a soft tube during the remainder of the whole procedure.

I would warn against allowing the stylet to remain within the tube below the mentioned limit, as, in the first place, we don't want to use a hard tube in the œsophagus, and second, the withdrawal of the stylet under this condition would be almost impossible. At any rate, our end in view—

the overcoming of the difficuly to the passage of the Nelaton tube—is fully reached by using the stylet only as far as the pharynx extends.

I would claim, therefore, that the stylet fulfils all the requirements of the case, dispenses with the co-operation of the patient, and that there should never be any further failure, the patient being willing and there being no organic stricture present, in introducing a soft-rubber tube into the stomach.

Fractured Ribs in the Insane.

A paper of much interest upon the subject of fractured ribs of the insane has been contributed to the last volume of the *St. Bartholomew's Hospital Reports*, by Dr. Claye Shaw. It discusses in the first place how it is that fractures occur. The author states that the detection of broken ribs in lunatics is not necessarily proof of violence on the part of an attendant, because it is difficult to imagine that attendants who know so well the consequences of being detected in any act of violence would deliberately, and for no reason, commit one so easily found out. Seemingly, it is right to say that fractures in the ribs of lunatics are not caused by hard direct blows, but by a slighter force which happens to take the patient when his body is placed at a disadvantage for resisting strain. Hence the absence of a bruise and the difficulty in finding out how these injuries occur. Dr. Shaw bases this opinion upon the fact that prize-fighters rarely receive any injuries to the ribs, although immense blows may be given upon the thorax, the explanation being that the body is in a position to resist the effect of the blow. After many experiments made by himself and Mr. Stansfield, Dr. Shaw ascertained that the breaking weight of a rib—the eighth—was among males, on the right side 15 11-16th lbs., and on the left 16¼ lbs.; among women it was 10⅞ lbs. on the right side, and 9½ lbs. on the left. He summarizes his results as follows: (1) That a considerable difference is found to exist not only in the weight of the ribs on the two sides of the body, but also in the average breaking weight. (2) That the lighter rib is often found to bear the heavier weight, and that there is no proportion between the weight of the rib and the number of pounds it is capable of sustaining, whence it would appear that physical conditions of structure have more to do with the strain-resisting power than has chemical change in bones. (3) That persons suffering from disease of the heart or blood-vessels bear less strain than others. (4) That persons suffering from advanced constitutional disease, such as phthisis, may have ribs that support a strain much above the average, and hence that there is no direct relation between constitutional strength and that of the ribs. (5) That when a blow causes a fracture this is dependent not so much on the weight of the rib and its power of bearing strain as on other conditions. Lastly, he remarks that the dictum that the ribs of the insane are more brittle than those of the sane is true to a very limited extent only, and is almost confined to those affected with degeneration of the circulatory system. He appends a table to his paper showing the weight required to cause fracture of the rib and the seat of the fracture in forty-five experiments which he made.—*Medical Press*, February 25, 1891.

Acetanilid for Chancre and Chancroid.

The *Journal de Médecine*, January 25, 1891, states that Basilevitch reports in *Nouveaux Remèdes*, November, 1890, that cicatrization took place in a short time as a result of sprinkling acetanilid on the surface of the ulcers in one case of chancre in a woman and in two cases of chancroid in men.

In these cases, acetanilid has the advantage over iodoform of being inodorous, and that large doses do not give rise to toxic manifestations. It is also less expensive than iodoform—an important consideration, especially in dispensary practice.

Foreign Medical Diplomas in Illinois.

The Illinois State Board of Health has decided that hereafter it will recognize no foreign diploma unless such diploma confer the right to practice medicine in the country in which it was granted. This rule applies to Austrian, German, Russian and Swiss diplomas, unless the holders have passed the State examination which entitles them to practice in those countries. It applies also to Canadian diplomas unless the holder be a licentiate of the Colleges of Phyicians and Surgeons, of Ontario and Quebec.

CLINICAL LECTURE.

GALVANISM IN THE TREATMENT OF DISEASES OF THE UTERUS.[1]

BY JOHN M. FISHER, M. D.

With a view to determine the value of galvanism in the treatment of pelvic disease in women, Professor Parvin, one year ago, gave me a place on the "gynecological clinic" for the purpose of treating such cases as I might think proper with the battery. In spite of serious drawbacks that attended our earlier work, and of a skepticism which dominated our minds at the outset, as to its possible value, we must confess to having verified at least some of the reported successes of more competent observers, in evidence of which we have here living witnesses—many of the patients themselves, who have undergone treatment by this means—to testify to its efficacy.

After giving the salient features in the history of each case, it may be well for you to note the number and time of the sittings, the pole that was placed in the vagina or uterus, the intensities as expressed in milliampères, and the results. A demonstration of the galvanic apparatus, with an explanation of its mode of action, and the treatment of a case in your presence, will occupy our attention at a subsequent lecture.

Case 1. Mrs. G——, æt. 21, married. I removed this woman's uterine appendages fifteen months ago for the cure of a septic salpingitis following a miscarriage. She made a good recovery. Soon afterwards, however, she began to have profuse uterine hemorrhages, recurring at irregular intervals, and continuing from one to three weeks. Every medical resource known to me was tried and failed. On May 13, 1890, after she had bled for more than three weeks, a positive intra-uterine application of galvanism was made, 60 milliampères for five minutes, with the result of arresting the bleeding within twelve hours. Since then she has had a mere "show" but once, extending over a period of two days. She is now in the enjoyment of excellent health.

Case 2. November 18, 1889, I was called to see Mrs. S——, who gave the following history: age forty-two, married, one child nineteen years old, no miscarriages. Six years ago she began to suffer with menorrhagia. She continued to grow worse with time, until within the last two years, she seldom knew of a day that she was "well," the hemorrhage having become almost constant, and at times so excessive that she was frequently obliged to resort to the use of tampons, and to take to her bed for weeks in succession. She stated that she was confined to bed almost half the days of the year, because of this trouble. At the time I was first summoned she had been in bed for more than nine weeks, flooding incessantly, save when this was temporarily arrested with tampons. Her weakened pulse, sunken eyes, blanched face and bloodless appearance of the local and vaginal mucous membranes, at once told the story; and, although she had been under the care of intelligent practitioners, men of large therapeutical resources, the bleeding during all of these nine weeks had not been checked for even a single day. After the removal of a cotton tampon, and the vagina being cleared of clots, blood was seen issuing from the uterine canal. The uterus was found to be enlarged, of a globular form, and freely movable. The anterior lip appeared to be the seat of a small intramural fibroid. The uterine cavity measured four inches. Fibroid uterus was diagnosticated. An intra-uterine positive galvanochemical caustic application of fifty milliampères of five minutes' duration was made;

[1] Delivered at the Jefferson Medical College Hospital, December 9, 1890.

with the result of arresting the hemorrhage at once. Four days later a second application was made, of seventy milliampères, for five minutes. Six days more elapsed and I found the patient sitting up with no hemorrhage. A third application was made, positive, intra-uterine, seventy-five milliampères, five minutes. November 30, slight bleeding recurred and continued for six days. The patient was about all the while, attending to household duties. December 9, positive cauterization, one hundred milliampères, five minutes. This was the fourth and last galvanic treatment until the following May, when five months had elapsed, during which she menstruated regularly, the "flow" extending over periods of four and five days; no clots, no pain. At this time—May 2, 1890—she was again seized with hemorrhages. I was out of the city, and the bleeding continued three weeks. On my return I found the patient in bed, blanched from loss of blood. I made a single positive application of galvanism, 100 milliampères, five minutes, with the result of checking the bleeding within six hours. Six months have elapsed since then, and the patient is in buoyant health and menstruation has been regular, lasting three and four days. A bimanual examination indicates that the uterus has been considerably reduced in size.

Case 3. Lizzie B——, æt. 27, single, has suffered with menorrhagia for four years. Lately the flow has covered periods of three weeks and more, with intervals of only seven and eight days. She suffers with frequent attacks of frontal headache and vertigo, and is extremely nervous and apprehensive. The mucous membranes in general present a blanched appearance. Within the past few years she has lost considerably in weight. Uterus retroflexed but movable, posterior wall the seat of a fibroid the size of a small lemon. June 20, 1890, the patient states that she has been bleeding continuously for three weeks. An application of galvanism, negative, intra-uterine, 40 milliampères, five minutes, was made. Three days later, still bleeding; another negative application, 60 milliampères, five minutes. Four days more elapsed, and she came to the clinic paler and weaker than at any time before, stating that since the previous treatment she had been confined to bed because of the excessive flooding. Blood was still issuing from the uterus quite profusely. A "positive" application, fifty milliampères, five minutes, was now made, with the result of arresting the bleeding within twenty-four hours—after it had persisted for more than four weeks.

Between June 27 and September 1, twelve intra-uterine positive applications of galvanism were made, with intensities of from fifty to one hundred milliampères, five minutes. After the last treatment the patient was taken with colicky pains in the abdomen, attended with nausea, loss of appetite and violent frontal headache, confining her to bed for a week. The last application no doubt excited a certain degree of pelvic inflammation.

This is the only case of all I have had under treatment in which such an unfortunate complication resulted. The patient has no symptoms at present that indicate permanent disability as a result of the attack. She has menstruated regularly since July, the flow covering periods of eight and nine days, and being profuse but not painful. The size of the fibroid has remained stationary. She has gained ten pounds in weight, and the signs of blood deterioration are no longer present.

Case 4. Mrs. R——, æt. 38, married for nineteen years, no children. The patient, on presenting herself at the clinic, had a large, smoothly-rounded fibroid tumor of the uterus extending to within an inch of the ensiform cartilage. She suffered from constant backache, vesical tenesmus, rectal distress, and a feeling of fulness, tension, and dull pains throughout the pelvis, shooting into the thighs—the latter symptom being especially annoying. From November 1, 1889, to November 26, 1890, twenty-nine negative intra-uterine applications of galvanism were made; the intensities varying between 100 and 150 milliampères, five minutes. To-day we have a report to make as follows: She menstruates regularly without pain, the periods covering from three to five days, flow not excessive. The sensations of fulness and tension are very decidedly relieved. The vesical tenesmus, rectal distress and abdominal pains and the pains in her limbs, have all disappeared. One year ago her girth measurement at the umbilicus was thirty-four inches, at present it is thirty inches; and, since this difference obtains with reference to all the measurements taken, I am sure you will not consider it extravagant when I say that this tumor has decreased in size to the extent of at least one-fourth its original bulk one year ago.

Case 5. Mrs. N——, æt. 24, married eight years, four children, one miscarriage nine

months ago after six weeks' gestation, to which she attributes her present ailments. Ever since she has had a profuse bloody discharge recurring at intervals of two weeks and less, at times only a few days intervening between the attacks, continuing for from several days to four and five weeks at a time. It is clotted and attended with considerable suffering. Sexual intercourse is painful, and frequently causes bleeding. She has severe occipital headache during menstruation. She has constant sacro-inguinal pains of a dull character, and a feeling of weight and dragging in the pelvis; all of which, as well as the hemorrhages, when present, are aggravated by exercise. The uterus is retroflexed and movable, the cervix enlarged and highly congested, the uterine canal patulous and measuring three and a half inches.

The bleeding was arrested within a few hours after making a positive intra-uterine application of galvanism, 50 milliampères, five minutes. On June 30, 1890, fourteen days after the first treatment with the battery, the menses appeared and continued for three days, profuse, but not painful. The fourth and last application of galvanism was made August 25, seventy-five milliampères, five minutes. Since treatment was discontinued she has menstruated four successive times, at intervals of twenty-eight and thirty days, with an almost absolute freedom from symptoms. She is no longer distressed with the sensations of weight and bearing down, sexual intercourse provokes neither pain nor bleeding, and she has been free from headache since electrical treatment was first instituted, save an occasional twinge during menstruation. The uterus is reduced in size, the canal contracted, but the flexion remains.

Case 6. Bessie F——, æt. 19, married one and one-half years, never pregnant, menses at fifteen, regular before marriage, continuing seven days, not painful. Shortly after marriage menstruation began to recur at shorter intervals than usual, until it appeared every two weeks; it continued from seven to ten days, clotted, and attended with excruciating colicky pains in the lower abdomen and pelvis. This still persists, and is becoming more pronounced with each succeeding period. The inter-menstrual periods are characterized by a constant feeling of distress over the hypogastrium, amounting—at times—to actual pain, severe enough to keep her awake at night. After five months' treatment with the dilator, combined with constitutional and intra-uterine medication without benefit, she was referred for electrical applications. The uterus was anteflexed and movable, the os the site of a mucoid discharge, the vaginal vault tender to the touch. Just before treatment with the battery was begun she had been bleeding almost continuously for more than a month. September 22 to October 10, 1890, four positive intra-uterine applications of galvanism were made, the highest intensity administered was sixty milliampères, the lowest forty, for five minutes. September 29, three days after the second treatment, the menses appeared, covering a period of five days, and painless. Exactly twenty-seven days had elapsed between the periods—a thing that had not occurred for more than a year before. The menses came at the regular time in November, lasting five days and being painless. Patient now has neither a pain nor an ache.

Case 7. Mrs. A——, æt. 33, married fifteen years, two children, third and last pregnancy ten years ago, miscarriage after three months' gestation, which was attended with excessive flooding. For a period of more than five years subsequently she suffered from frequent and profuse uterine hemorrhages. At present she has what might be termed her regular menstruation at intervals of about four weeks, the "flow" continuing for eight and nine days, profuse, clotted and painful. The inter-menstrual periods are characterized by occasional hemorrhagic discharges, variable in quantity, but not excessive. Sexual intercourse is painful, and frequently followed by bleeding. She suffers from constant inguinal and hypogastric, dull, aching pains, and from a feeling of weight and distress in the pelvis; all of which are aggravated at the time of the menses and following undue exercise. The only time at which she enjoys comparative comfort is while lying in bed. The uterus is in the first stage of prolapse, movable, enlarged and rigid. The cervix is of a pale, ashy color, and enormously enlarged. The uterine canal is patulous, and the site of an ichorous, watery discharge. The cavity measures three and one-quarter inches.

Between July 29 and September 5, 1890 (38 days), five negative intra-uterine applications of galvanism were made, the intensities varying between fifty and seventy-five milliampères, for five minutes. She has menstruated regularly and has been absolutely free from pain since August last. She has

had no bleeding since July. Sexual intercourse is neither painful nor followed by bleeding. The uterus is reduced in size and the canal measures less than three inches, and is contracted and free from discharge. The patient states that she has not been so well for ten years past.

Case 8. Mrs. C——, æt. 45, married 13 years, two children, one miscarriage twelve years ago, after a six and a half months pregnancy, attended with convulsions, and excessive flooding. The convalescence was prolonged, several months elapsing before she was able to resume household duties. The last child was born five years ago, after a normal labor. She dates her present trouble from the miscarriage, after which her menses became more profuse and painful. She has been suffering with constant, heavy, dragging and dull pains through the pelvis ever since, with pain in the back and groins, all symptoms being aggravated on locomotion. At that time menstruation was continued for a week and longer, was abnormally free, and very painful for several days preceding and during the "flow." Leuchorrhœa was profuse. Micturition was frequent at the time of the menses. She had vertical and occipital headache, with frequent nausea and vomiting. The hypogastrium was tender to pressure. The uterus was low down in the vagina, enlarged and movable; the cervix passively congested, eroded and enormously enlarged, the uterine canal patulous, measuring four inches, and the site of a profuse muco-purulent discharge. The vaginal vault was extremely tender to the touch. The abdomen was enlarged and pendulous, requiring a binder during the day, and a pillow to support it at night. The patient has had twenty-one intra-uterine applications of galvanism, both negative and positive, since February 3, the intensities ranging from 35 to 75 milliampères, five minutes. The time elapsing between treatments, owing to the patient's inability to come regularly, has varied between five days and two months. She is still under treatment.

She has undergone a slow but gradual and progressive improvement since the day the battery was first used, both anatomically and symptomatically. The whole uterus has undergone great diminution in size. The cavity now measures less than three inches, and there is decidedly less tenderness of the pelvic floor. The abdominal walls, the patient herself observes, have regained some of their lost tone, so that now the pillow for support at night can be dispensed with. The menses are regular, continue from three to five days, and are painless. The general pelvic distress is much relieved. In her own words, electricity has done her more positive good than all other means of treatment combined for years previously.

Case 9. Agnes F——, æt. 27, single, for a year preceding puberty suffered from frequent attacks of colicky abdominal pains, and constant backache. Her menses began at seventeen, were regular, and continued for one and a half days, scanty. The very inception of the "flow" was always attended with excruciating uterine pains, every moment contributing to her suffering for from five to six hours, rendering the free use of morphia, or whatever narcotic might be at hand, a necessity. She had been under the constant care of physicians for years, and was treated with the battery from Jannary to July, 1888, without benefit. She does not know the kind of electricity that was used, nor how it was administered. She applied at the clinic October 28, 1889. The uterus was in the normal position, and movable, and presented cervical endometritis. A week later the cervix was dilated under ether. Four days subsequently the menses appeared, just as painful as ever. January 3, 1890, negative intra-uterine galvanism was used, 45 milliampères, five minutes. Menses came on in three days and continued for four days—a longer period than ever before—with comparatively little pain. Two negative applications preceded the following period, which began February 6, and continued for five days, painless. The fourth and last galvanic treatment was on February 13, 1890, since which time she has menstruated regularly, the "flow" continuing for four days without pain.

Case 10. Mrs. G——, æt. 28, married two years and a quarter, no children, complained of excessive pain on sexual intercourse, the mere attempt at which excited violent spasmodic contractions of the muscular structure of the vagina, and threw her into a state of nervous excitement and trembling, frequently rendering its accomplishment impossible. The sensibility is of such an aggravated type, that, as soon as the finger touches the vulva, this neuro-muscular condition supervenes, the patient at the same time giving evidence of suffering pain, and evincing great nervous disturbance. This trouble has been the source of much unhappiness between herself and husband.

She was under treatment at this clinic two years ago (shortly after marriage) when the application of cocaine and repeated dilatations gave temporary relief. She returned with the disease in an aggravated form. Between September 22 and October 6, 1890, five applications of galvanism were made, vagino-abdominal, 15 to 30 milliampères, five minutes. After the third application the spasm and pain were entirely relieved, and coitus was satisfactory. The cure has remained permanent.

If time permitted I might continue to review the histories of ten additional patients here to-day—cases duplicating some of the various forms of uterine disease already illustrated, and in which the application of galvanism proved its curative properties to no less a degree.

All of these cases had been subjected to various other modes of treatment previous to the employment of electricity, with but slight benefit in some and none at all in others; and in order to be certain that the results obtained are the legitimate outcome of the galvanic applications alone, no other means of treatment were resorted to either during or subsequent to the use of the battery. In some of the cases of chronic parenchymatous metritis especially, improvement would in all probability have attended our efforts much more rapidly, and the end in view would have been attained with greater certainty, had the electrical treatments been supplemented by other therapeutic measures—derivative, antiphlogistic and tonic.

Of six uterine fibroids treated with the battery, four were more or less hemorrhagic in their tendencies; and in every one of them the intra-uterine application of the positive pole proved its hemostatic properties immediate and remote, and the results obtained have been lasting. In only two of the cases has there been a positive and indisputable reduction in size. When we consider, however, that this was the object in view in but three of the entire number of cases treated, it certainly speaks well for the battery. The case in which it failed was a fibroid of enormous size. The patient was under treatment about six weeks, during which the tumor kept on growing at its usual rate. After the eighth application the patient ceased coming to the clinic, and was lost sight of.

Where the object was to arrest hemorrhage alone, the tumors being small, and giving rise to no other untoward symptoms, the indication being met, the treatment was discontinued. In none of the latter has there been any increase in size. On the other hand, I cannot say that any have grown smaller; slight changes may have taken place, but owing to their location, the sense of touch—a most uncertain means of measurement—is our sole reliance in determining their dimensions.

The use of galvanism in the treatment of pelvic adhesions and uterine displacements, save in so far that it often corrected concomitant diseased conditions of the organ and relieved symptoms, appears to have given negative results. But you must not accept my statements on these questions as conclusive. I may have failed where others more skilled in diagnosis, and more dexterous in the use of apparatus, and possibly less timid than myself in applying heavy currents, might have succeeded, and with an increasing experience my views in some respects may undergo a change.

Not every woman coming to your office having a chronic endometritis should have an electrode thrust into her uterus. There are certain diatheses, and diseased conditions of other organs, as well as feebleness of constitution that predispose to the development of this disease, so that it often is but one of several diseased mucous membranes, the result of a special tendency of a constitutional state. Turn your attention to the predisposing cause first; the endometrium may require attention, but not always. Hemorrhage from the uterus even must not be regarded as an invariable evidence of disease of the organ *per se;* it may be, and often is, an expression simply of a general vascular tension, or other constitutional condition, depending upon alcoholic excess, diseased state of the blood-vessels, heart, liver or kidneys, or of impairment of nervous function, which simple hygienic measures and intelligently applied pharmaceutical remedies may correct without any intra-uterine tinkering whatever. Just so with diseased states of the parenchyma of the organ; electricity should be regarded as an auxiliary in their treatment, and not as a "cure-all" to be used in every case, and to the exclusion of everything else. Always bear in mind that a chronically inflamed uterus is enlarged, that it drags upon surrounding structures, and that, owing to interference with the return circulation, it is in a state of constant passive congestion. In conditions like this,

five things are always in order—rest, tonics, saline cathartics, hot vaginal injections, and glycerine tampons. These of themselves, diligently applied, will often bring about vast improvement, and effect a cure in not a few cases. These things considered, we think of the electrode last, because every intra-uterine operation carries with it a certain amount of risk, and nothing should be introduced into the uterine cavity unless it is specially indicated to obtain a definite object in treatment.

It follows, therefore, that a gynecological electrician, above all, should be a good, all-round general practitioner, with special experience in the treatment of pelvic disease. A correct diagnosis is of first importance to successful treatment, and the mere specialist, who sees nothing except through a vaginal speculum, who concerns himself little about the value of drugs and properly regulated regimen, and whose therapeutic armamentarium consists of an applicator, a knife, or an electrode, will frequently fail to give relief, and often do positive harm.

Gynecological diagnosis, among the most experienced, is often difficult and obscure. Dr. Joseph Price reports cases in which ectopic gestation has been diagnosticated as ovarian cystoma, pyosalpinx and fibroid tumors. Fibroids have been denominated ovarian cysts and *vice versa*. Dr. Anna Fullerton reports a case in which a small dermoid cyst had been called a prolapsed ovary, another of "retroflexed uterus fixed by adhesions with hematosalpinx of one side, and hydrosalpinx of the other, accompanied by hemorrhage, which had been thought to be in a condition resulting from miscarriage, and curretting of the uterus was advised, or the application of electricity to the endometrium." An error in diagnosis, such as the one made in the last case, might have proved fatal to the patient had the treatment originally advocated been carried out.

In the present state of our knowledge of pelvic disease, great caution should always be observed lest we do harm by the application of local measures hastily adopted. Founding my convictions upon individual experience, in connection with what I have witnessed at the operating table, I, to-day, do not consider it a safe procedure to make cauterizing intra-uterine applications of galvanism, if evidence of disease of the uterine adnexa is present. That disease of the appendages exists, is sufficient warning, because it is no more given to a gynecological electrician to make an exact diagnosis than it is to the abdominal surgeon whose preconceived opinions are often shown to be erroneous by what he finds on "section."

COMMUNICATIONS.

SUGGESTIONS FOR ABDOMINAL OPERATIONS AND AFTER CARE.

BY WM. GOODELL, M. D.,
PROFESSOR OF GYNECOLOGY IN THE UNIVERSITY OF PENNSYLVANIA.

[The following is the form of letter prepared by Prof. Goodell, to be sent to physicians for whom he expects to perform an abdominal section. It furnishes full instructions in regard to the preparation for operation and the after care of the patient, with the necessary apparatus and appliances.]

Please procure the following articles for the operation of abdominal section to be performed ———, at ——— o'clock, on your patient, ———.

Two yards rubber plaster.

Two rolls of raw cotton, which have been well baked in an oven, and while hot carefully wrapped up in clean brown paper.

Two yards and a half of all-wool flannel, for two binders.

Two pounds of ether, together with an Allis's inhaler; or else a clean towel without a fringe, and a newspaper, with which to make an ether-cone.

Two ounces of Monsel's solution of iron.

One gallon and a half of a 5 per cent. solution of crystalized carbolic acid.

Half an ounce of iodoform.

Some antiseptic cotton and some tablets of corrosive sublimate.

Whiskey, with cup, spoon and sugar.

A pin-cushion, with large pins and safety-pins.

A washstand, with pitcher, basin, slop-jar, soap and nail-brush.

One china basin for the sublimate solution.

Two new tin basins, and one tin cup.

A bucket and a pitcher of hot water.

A small tub and an empty bucket.

Two kettles of boiling water, ready on the range.

Pure cold water in abundance, that has been boiled and kept in covered vessels.

Two large platters, or meat dishes, to be used as trays for the instruments. Or a tin tray may be made nineteen inches long, twelve wide and three deep.

Six bottles filled with hot water and tightly corked.

Three clean kitchen aprons for the operator and his assistants.

One small table for the basins.

Two tables on which to operate, each one not less than four feet long, and about two feet wide. Or an operating table may be made twenty-two inches wide, thirty-one inches high and six feet long.

One empty wine-bottle for the aspirator.

One clean blanket for patient's lower extremities.

Clean towels, clean sheets, clean blankets.

Clean comforters and clean pillows.

Have all the foregoing articles in the room in which the operation is to take place.

Early in the morning of the day preceding that of the operation, let your patient get her bowels thoroughly opened—preferably with Rochelle salts—and afterwards eat sparingly of liquid food. Next morning her lower bowels are to be moved with an enema of soap and water, and the vagina is to be washed out with a douche of a 1 : 2,000 solution of mercuric bichloride. She should then take a warm soap bath, be washed clean by her nurse, put on clean night-clothing and go to a clean bed.

To avoid ether-vomiting her breakfast should consist merely of tea and toast, or of a cup of beef-tea, or of a goblet of milk, and, thereafter, she must eat nothing more. She must not get up, but must stay in bed until the hour fixed upon for the operation, when she should put on a flannel sacque and woolen stockings and drawers. The bedstead, on which your patient is to lie after the operation, should be furnished with a mattress and not with a feather-bed.

The room in which the operation is to take place ought to be a separate one, so that the patient may be etherized in her sleeping-room, and not be unnerved by witnessing the needful preparations. Several days beforehand, the carpet of this operating room should be taken up, and the curtains taken down for good. The closets and bureau-drawers should be emptied, and the whole room — floor and walls — be thoroughly cleansed and aired. Early in the morning of the day fixed upon for the operation, this room must be heated up to at least 70°. After the operation your patient may occupy whichever of these two rooms she prefers.

Not more than two assistants—viz., yourself and another physician—will be needed, and bearing in mind that the most common cause of danger from this operation is septicemia, let both of you take a soap-bath, put on clean clothing, and avoid seeing on that morning any case of zymotic or of contagious disease. Let these precautions be observed also by those medical friends whom you may invite to see the operation.

The treatment after the operation needs careful attention. Your patient must be made warm with the hot-water bottles, and be kept perfectly quiet. For several days no one should see her but yourself and the nurse. For obstinate vomiting, which comes partly from the ether and partly from the shock, whiskey or chloral, or the wine of pepsin may be given in small doses, frequently repeated. Sips of very hot water, or a tablespoonful every hour of a mixture containing equal parts of lime-water and of cinnamon-water, are also good remedies. If the vomiting is very stubborn, a hypodermic injection of morphia will often allay it; so also will one of atropia. I have seen it yield to frequently-repeated doses of five grains of bismuth, one drop of dilute hydrocyanic acid and three drops of wine of ipecacuanha. Flatus is another very annoying symptom, which, however, can very generally be dispersed by turning the patient on her side and inserting a flexible catheter as high up the rectum as possible. If this fails to relieve it, or the temperature rises simultaneously with its appearance, saline cathartics should be given, aided, if needful, by turpentine enemata. A very safe rule to follow is, to open the bowels whenever wind does not escape per rectum and tympanites begins to show itself.

For the first twenty-four hours after the operation *nothing whatever* should be given to the patient excepting sips of hot water or of hot tea without sugar or milk, and an occasional teaspoonful of old whiskey; but even these should be given sparingly. After that time, tablespoonful doses of milk, of beef-tea, or of barley-water may be given every two hours. This diet must then be gradually increased, and especially if wind begins to escape from the rectum. If, during the first twenty-four hours, nourishment seems indispensable; or if, later on, more nourishment than that given by the mouth is needed, you must resort to nutrient en-

emata of peptonized milk, or of beef-tea with whiskey.

Should the patient be able readily to pass her water into a urinal, it need not be drawn off. Otherwise, it must be drawn off regularly every six hours for the first two or three days. Later than this, the catheter need not be used so frequently, but only when the patient wants it. On the morning of the third or the fourth day, even earlier if tympanites appears, the bowels must be opened, preferably with saline cathartics, and thereafter they are to be moved every other day. The cathartics which I prefer are teaspoonful doses of Rochelle salts every hour, or a Seidlitz powder every two hours.

No anodyne whatever need be given, unless called for by great pain, or by excessive restlessness. Should the body-heat indicate a temperature of 101° or over, an ice-cap or a bladder filled with ice should be kept on the head of the patient as long as it does not chill her, and it feels comfortable. Peritonitis, or other septic symptoms, must be treated with ice to the pit of the stomach in addition to that on the head, and with brisk saline cathartics followed by large doses of quinia, and by morphia enough to allay the pain.

If a drainage-tube has been put in, it is to be sucked out dry every two, three or four hours, by means of a small syringe to the nozzle of which a short piece of rubber-tubing has been attached. Every time this is done, a fresh piece of sublimated cotton is to be placed over its mouth. Twice a day should the drainage-tube be lifted up half an inch, and turned wholly around on its axis. Unless this is done fringes of the omentum, or shoots of organizing lymph may get into the tube-holes, and by swelling up inside of the tube, prevent it from being withdrawn without great and dangerous violence. The drainage-tube is to be removed whenever the fluid withdrawn from it becomes clear and straw-colored like serum. The opening left in the wound must be dusted with iodoform and covered with sublimated cotton or gauze.

The dressing, being antiseptic, need not usually be changed until a week has passed. Every stitch may then be removed, and the wound may be washed with a 1:2,000 mercuric solution, dusted with iodoform and supported with long and narrow strips of rubber plaster. Over this some sublimated cotton or gauze should be placed, and over all a clean binder. For fear of a weak cicatrix and the formation of a hernia at the site of the wound, the patient should not get out of bed for at least two weeks, and should for six months more wear some kind of gored binder, or an abdominal supporter like "The London Supporter."

If the foregoing directions do not cover every point or do not meet every contingency that may arise, do not hesitate to consult me by letter or by telegraph as often as you may wish.

LAPAROTOMY IN INTESTINAL OBSTRUCTION.—REPORT OF A CASE.[1]

BY ALEX. McALISTER, M. D.,
CAMDEN, N. J.

The time for operation in cases of intestinal obstruction is when the diagnosis is made, and before complications and structural lesions have taken place in adjacent and remote organs, and when the patient is in the best possible condition for operation. Surgery has made rapid strides, and in no special field has there been more advance than in intestinal surgery. The mortality from delay, incorrect diagnosis, timidity, ignorance and prejudice in the past has been very high. We have a safe and reliable, speedy and accurate method of diagnosis of intestinal obstruction, namely, Senn's hydrogen gas inflation of the intestines. Senn deserves much praise for his inventive genius, originality and experimental research in intestinal surgery. Keith, in speaking of the failures in abdominal surgery and hindrances to its progress, states that most of the injury has been done by the surgeon himself. Time waits for no surgeon. Delays are dangerous. Formerly, the phrase, "obstructed bowels" was synonymous with death. To-day it means: use the test, operate, remove the cause and let the patient live. When done early by expert surgeons, and before structural lesions have formed, laparotomy for intestinal obstruction will have as small a mortality as ovariotomy. The physician of the present and future, who is not equipped to make the special diagnosis of obstruction, operate for the removal, or have a surgeon operate, and before serious tissue lesions have taken place, is most certainly highly culpable and derelict of duty.

[1] Read before the Camden County Medical Society, February, 1891.

The best time to operate is when the diagnosis is made, and made early. Wyeth states: "Do not wait longer than the lesion of intussusception is recognized. Within the first twenty-four hours the prognosis will be more favorable, and the danger of a fatal termination will be increased with each day thereafter." If volvulus is not removed within a few hours by other treatment, abdominal section should be performed, the hand should be introduced and the loop should be untwisted. Constriction by bands, the vermiform appendix, the pedicle of an ovarian or uterine tumor, the Fallopian tube, diverticula, strangulation through slits in the omentum and mesentery and adhesions between the contiguous loops of intestines, demand early operative interference, as do all other forms of intestinal obstruction. That taxis should not be done longer than five or ten minutes at any one effort. It may be repeated at intervals of half or one hour, within the first six hours of the history of strangulation. After twelve hours, it should not be practiced. The majority of cases which end fatally are those in which strangulation has existed twelve or twenty-four hours or more before surgical interference. Abdominal section under asepsis and antisepsis in a patient not exhausted by suffering or disease, is almost free from danger, when done early by a surgeon skilled in the technique of intestinal and abdominal surgery.

Scientifically practiced massage and taxis have a limited range of application in the treatment of intestinal obstruction. They are applicable to cases of obstruction due to a foreign body, an enterolith or fecal accumulations, and should be resorted to only before inflammatory changes have developed at the seat of obstruction, and while the patient is under anæsthesia. The rule now is not to wait hours, or a day, to do taxis, but to do it only for fifteen minutes, and never over thirty.

Senn states: "True intestinal obstruction, whatever its cause may be, is as strictly a surgical affection as strangulated hernia, and remediable only by the same kind of surgical treatment." To let a patient die of the consequences of a removable cause of obstruction, without an operation, is a reflection upon the advances of modern aggressive surgery. In doing an abdominal section for obstruction, the aim of the surgeon should be to save life, to operate quickly, safely and cautiously, and not to do an ideal operation, but to economize time, minimize shock, lessen the stage of anæsthesia, prevent unnecessary extrusion of the bowels, and protect them with hot aseptic towels; to irrigate with hot aseptic water, and prevent complications, making all the details of the operation aseptic from beginning to end.

The technique of this operation has been much simplified by Senn's intestinal anastomosis, lateral apposition, lateral implantation and intestinal exclusion, and Senn's modification of Joberts' operation by circular enterorrhaphy, will greatly lessen the mortality of intestinal obstruction in the future.

On July 14, 1890, I was called in consultation by Dr. Kensinger, to see J. S., thirty years old, born in Poland, by occupation a painter. He had been suffering with symptoms of obstruction for about four days. His abdomen was distended and tympanitic, and there was some dulness in the right flank. His extremities were flexed; and his expression anxious. He had fecal vomiting and great and frequent abdominal pain, referred to the umbilicus. His pulse was 130; his temperature $102\frac{3}{5}°$; his respirations 30.

I urged immediate operation, which was readily assented to by the patient and his relations. I operated, being assisted by Drs. Kensinger and Sherk. The patient was etherized, an incision five inches long was made in the linea alba, between the umbilicus and the pubes. Several loops of intestine presented, which were immediately covered with towels wrung out of hot water. Passing my hand into the cavity, after careful examination, I found a loop of ileum about eight inches long, about two inches below the umbilicus, twisted upon itself from left to right. The omentum was pushed firmly against it, and the part of the intestine where the twist existed was very dark in color, and looked gangrenous. I also found small spots throughout the small intestine which also looked gangrenous, and the intestines were congested looking, and very much distended with gas, which escaped by the rectum, after the twist was released.

Irrigation was copious and thorough, and some water was left in the cavity. No drainage was used. The incision was closed with silk. The duration of the operation was about a half-hour. An antiseptic dressing was applied, and the patient was

placed in bed. Very little shock followed the operation, and no vomiting. Reaction was rapid. The bowels were freely moved. In less than an hour after the operation the patient was given drachm doses of sulphate of magnesia, every two hours, and by the next morning he had passed a house-bucketful of feces. His temperature was 100°. After this convalescence was uneventful.

Two weeks from the time of the operation he was back at his trade, and he has been perfectly well up to date.

ARTERIO-CAPILLARY FIBROSIS.[1]

BY AUGUSTUS A. ESHNER, M. D.,
PHILADELPHIA.

Every cell inherits from its parent cell a certain lease of life, at the end of which physiological death occurs. This period, however, may be influenced by external conditions. Premature death is pathological. We cannot recognize a pathological longevity. Similar laws apply to the human individual, the composite of a vast aggregation of cells of widely differentiated function.

The life of man may be divided into three periods: that of evolution, of growth, of development; that of maturity, of perfection; and that of involution, of decline. The first begins with birth, the last ends with death.

During the period of growth and development, tissue-change and destruction—catabolism—are more than offset by tissue-construction and repair—anabolism. Nutrition exceeds waste. Building-up is more active than tearing-down. With the activity of life comes the demand for the highest differentiation of function of which the organism is capable. This represents the perfect individual. For a time, a condition of equilibrium is maintained. Sooner or later, however, the tide begins to turn. The equilibrium is disturbed. Waste exceeds repair. The cellular assimilative function becomes impaired, the constitution of the nutritive fluids defective. Tissues and organs are imperfectly furnished with the materials for their maintenance. Vascular changes occur. In a vicious circle, one baneful influence reacts upon another. The entire organism is reduced to a condition of deterioration. Finally, the state of nutrition falls to so low a level as to be insufficient for the purposes of life, and functional activity comes to a standstill. This is the physiological process, as it occurs at advanced age, and constitutes the condition of senility. Occurring at an earlier period, however, the process becomes pathological, recognized clinically by signs and symptoms which may be conveniently included in the designation premature senility.

As the component parts of the organism depend for their sustenance upon the nutritive elements of the blood, so will their functional stability be governed by the quality and quantity of the circulating medium. Thus, we would be led to look to the blood as containing the excitant which induces the earliest changes. The function of the cell once impaired, the deleterious action of the blood would be augmented by the retention of matters which it was the part of the cell to remove, and the addition of products from the degeneration of the cell.

Pathologically, the condition under discussion may be considered a general fibrous substitution and hyperplasia, displacing parenchymatous structures and narrowing the lumen of arteries and capillaries; hence the names arterio-capillary fibrosis, arteriosclerosis.

The histological changes may arise in one of two ways, or in a combination of both. When tissue degenerates or is destroyed, nature endeavors to make restoration. The attempt is often only partially successful. The newly-formed tissue is apt to be of a lower grade than that which it replaces. The more highly organized the latter, the wider, of course, is the variance. In this way, fibrous tissue takes the place of vital structure. This is illustrated in the cicatrix, be it cerebral or cutaneous or parenchymatous. Under other circumstances, there occurs a primary hyperplasia of pre-existing connective-tissue, perhaps of a subacute or slowly chronic character, displacing the tissue proper to the organ, and finally leading to its disorganization. These two processes may be illustrated by the modern pathological conceptions of the changes that occur in certain diseases of the central nervous system. In the acute inflammatory disease known as anterior poliomyelitis, the destruction of the ganglion cells in the anterior horns of the gray matter of the spinal cord

[1] Read before the Philadelphia County Medical Society, March 11, 1891.

is followed by a reparative process, in which fibrous tissue replaces that which has been destroyed. In the systemic scleroses, posterior and lateral; in the degenerations, ascending and descending, primary destruction of axis-cylinders takes place, with secondary substitution of fibrous tissue. In insular sclerosis, on the other hand, there is at first an increase in the connective-tissue, followed by gradual destruction of nerve-elements and interruption of function. The difference is that between inflammation and cirrhosis. Solid viscera may be unchanged in size. They are rarely enlarged, but often shrunken, from contraction of the fibrous elements. The coats of the vessels are thickened, and their lumen narrowed. In whatever structure the process begins, it is slowly progressive, especially if the exciting influence be maintained. The change, as it affects the arteries, is to be distinguished from atheroma, with which it may be associated. Both are evidences of senile disorganization. In atheroma, however, the process is one of fatty degeneration of the intima, giving rise to ulceration, which is in turn followed by cicatrization and calcification. In the one condition, clinically, the vessel, to the eye and to the examining finger, is tortuous and resistant; in the other, it is rigid and unyielding, like a pipe-stem. It is the difference between fibrous and calcareous infiltration.

The etiological elements concerned in the production of arterio-capillary fibrosis are comprised in the group of noxæ which we now know as toxic and infectious, and include syphilis, alcoholism, lead-poisoning, gout, rheumatism and infectious diseases in general. Heredity, too, probably plays some part in transmitting a predisposition to the occurrence of fibrous degeneration.

Perhaps the most conspicuous symptom, and that for which the patient first seeks relief, is shortness of breath on the slightest exertion. The onset of this condition is so insidious that the patient is unaware of its existence, until it is suddenly revealed by a demand for some special activity. With it is often associated palpitation, which the patient is apt to describe as a fluttering of the heart. The cardiac action is found to be irregular, perhaps intermittent, with occasional duplication of the second sound or an abortive first. The second sound is distinctly accentuated at the base. The pulse is tense and resistant. The temporal arteries are prominent and tortuous. In addition, the patient complains of coldness of the extremities or of numbness or of formication, with, perhaps, some weakness. There may be vertigo, especially on sudden changes of posture, lightness in the head, as the patient says. The memory is impaired, and there may be headache. The knee-jerk is frequently exaggerated, but not always. Often there is tremor, and sometimes nystagmus. In some cases, the complexus of symptoms approaches that seen in insular sclerosis, in others that seen in paralysis agitans, though typical of neither. It may be that such cases represent incipient stages of the one or the other of these affections, which, in their turn, perhaps, may be more intimately related than we as yet know. Occasionally, we meet with transient paresis and local paralysis, sometimes ascribed to uremia. It seems easier to explain the occurrence of these on the assumption of partial vascular occlusion. The feet are sometimes swollen. There is apt to be increased frequency of micturition of a urine of low specific gravity, but rarely containing albumin or casts.

The train of symptoms here outlined may be readily explained by the pathological lesion. How common it is at autopsies to find organs the vessels of which gape with open mouths, while, during life, the only condition determinable was such an association of symptoms. It is neither nephritis nor arteritis, neither myocarditis nor cerebritis, but a diffuse fibroid change, the manifestations of which are perhaps most patent in the small arteries. Thus, we see associated with this condition miliary aneurisms in the brain, which we now know to be so generally antecedent to cerebral hemorrhage. In the absence of aneurism, the vascular fibrosis may alone act as a predisposing cause of rupture. The narrowing of the cerebral capillaries may become so marked as to permit of the formation of thrombi *in situ*, thus explaining certain cases of hemiplegia in which cardiac lesion or other source of embolism cannot be detected. It is also probably in the thickening of the wall of the capillary and the narrowing of its lumen that certain cases of transient or permanent loss of power, in which the severity of the symptoms soon abates, may find explanation. The derangement of cardiac function is a result of defective nutrition and innervation. The shortness of breath is brought about by the cardiac incompetency, by the vascular changes in the pulmonary structures, and, finally, by lowered

innervation, in some cases aided by concurrent emphysema. Other visceral symptoms are due to changes of a similar nature in the respective organs. The extremities are cold because the blood-supply through the narrowed vessels is imperfect.

In the consideration of the treatment of this condition, not much need be said in the way of prophylaxis. "All the medicines in the world will not replace right living." It is the secret of longevity.

In the general management of the case, the individual is to be directed to lead a tranquil life, to avoid excitement and undue physical exertion, to partake of a light, nutritious diet, which, with benefit, may include a liberal supply of milk, and to take an occasional saline laxative.

Of medicaments, I have personally had the most gratifying results from the administration of nitro-glycerin, in combination with digitalis when the cardiac action is feeble or its rhythm disturbed. Nitro-glycerin is a diffusible stimulant, causing dilatation of the peripheral capillaries, thus permitting a flushing of the tissues with arterial blood, and promoting nutrition. By diminishing the resistance in the vessels, the demands upon the heart are lessened, while this organ, being better nourished, is more competent to carry on its functions. Beginning with one minim of a one-per-cent. solution three times a day, the dose is progressively increased one minim every second day, until physiological effects—flushing of the face, sensation of a band around the forehead, headache and dizziness—are observed. Probably the most appropriate menstruum is spirits of nitrous ether, the action of which, as a nitrate, is synergistic. In administering digitalis, I like to prescribe two to five minims of the tincture in two drachms of the infusion, in this way obtaining the benefit of all the principles of the crude drug soluble in alcohol and in water.

Strychnine and atropine may prove useful adjuvants in the treatment. Under certain circumstances, it may be desirable to substitute strophanthus for digitalis. Caffeine or cocaine may fulfil certain indications. Cod-liver oil might be used as a nutrient, alcohol as a stimulant. Iodide of potassium is of doubtful utility, except during the active stage of syphilis.

The conclusions I wish to record are: That there is a pathological condition in which the manifestations of senility occur prematurely, and that the best means of combatting it is by improving the general nutrition and giving tone and stability to the cardio-vascular apparatus—a healthy nutritive fluid, with a competent distributing apparatus.

PERISCOPE.

Use and Abuse of Drainage in Surgery.

In the *Medical Record*, March 14, 1891, Dr. James E. Moore, Professor of Orthopedic Surgery in the University of Minnesota, says: The besetting sin of our profession is our tendency to go to extremes. We discover something the judicious use of which would be of untold value to the human race, and are not content with its proper use, but must needs overuse it until its use becomes an abuse, when a reaction sets in and abuse is many times followed by disuse. In the matter of drainage of wounds we are still in the stage of abuse. Reaction has already set in, and inasmuch as proper drainage is such a vital part of surgery, it is our duty to study the subject carefully and not allow disuse to follow abuse. This reaction first began in abdominal surgery, and already we have learned that in a certain class of cases in which we at one time thought drainage an essential, we get the largest percentage of recoveries without drainage. Laparotomists have pretty nearly arrived at the truth, viz., that septic cases and doubtful cases should be drained, and that aseptic cases are better without drainage. I fear that in this important branch of surgery the reaction has a tendency to go too far, and that certain cases are left without drainage that would be better with it. We can also see some reaction in amputation wounds, where, instead of the sewer pipes of former days, we use drainage-tubes of smaller size, or none at all.

We, as members of the grandest profession on earth, have weighty responsibilities, and are held strictly accountable for our deeds and misdeeds, but, being only human beings, are entitled to the privilege of changing our views with increase of knowledge. In fact this is the only way we can advance. The very fact that our responsibilities are such weighty ones should remind us that we should guard against our besetting sin and avoid extremes. This can only be done by refusing to accept the *ipse dixit* of any man, no matter how exalted his

position may be, and by basing our change of views upon facts, instead of following in each other's wake like a flock of sheep.

The thorough drainage of wounds has been considered of primary importance for many years, but when Chassaignac suggested the use of drainage-tubes in 1855 his reason for draining was very different from that of the surgeon of 1890. He drained to allow of the free escape of pus. We drain in recent wounds to prevent the formation of pus. The necessity for drainage in an infected or suppurating wound is universally understood. The more perfect the surgeon becomes in his antiseptic methods the less he needs drainage-tubes and their various substitutes, and when he arrives at that stage of perfection in his methods that insures him an aseptic wound every time he operates he can dispense with them altogether. In all recent works on surgery we are advised to use drainage-tubes to carry off the excessive discharges from a wound, but we are not advised to make an opening at the seat of a fracture to carry off the discharges. Those who first learned of the value of drainage in open suppurating wounds, also learned that Nature took care of the discharges from a subcutaneous wound. When we have so perfected our methods of wound-dressing that we can place an open wound in the same condition as a subcutaneous wound we will no more think of draining in one any more than in the other. If a wound is aseptic Nature will take care of the discharges, just as she does in a subcutaneous wound. In a simple fracture of the femur there is much greater effusion of blood and serum than in any operation wound, and we never think of draining it off. Nature takes care of it promptly, the only disturbance being a transient rise of temperature.

Twenty-five years ago surgeons drained to carry off the pus. Fifteen years ago they drained to carry off the discharges so that they would not putrefy. At the present time we drain largely from force of habit. We no longer believe in spontaneous generation, or that the discharges putrefy without first having been infected from without. Blood in an aseptic wound becomes partly absorbed and partly organized. Serum should not be looked upon as something to be gotten rid of, for it undoubtedly has an important function to perform in the reparative process. In certain cases that we are learning more about every day, viz., infected cases, we must always drain. I maintain, however, that in aseptic cases drainage by means of rubber or other open tubes is not only useless but adds an element of danger. We learned the value of drainage when septic surgery was practiced, and notwithstanding the fact that our reasons for drainage have undergone very radical changes, we have been using drainage-tubes, too, nearly like we did at first. The principal difference is, that we originally allowed the drainage-tubes to protrude through the dressings, thereby infecting every wound. We are now very careful to cover the ends of the tubes and to allow everything to pass out, and nothing to pass in through them, which is an exceedingly difficult matter. Aside from the fact that a drainage-tube is a foreign body and interferes with primary union, the one great danger is that it keeps an entrance-way open through which germs may enter and infect the wound.

It is customary to close small wounds in all parts of the body without drainage with very satisfactory results. I can see no reason why a large wound should require drainage any more than a small one, for the amount of absorbing surface bears the same proportion to the discharges in the one as in the other. I believe we have allowed the size of the wound to influence us too much when deciding whether to drain or not. The character and not the size of the wound should decide the question. I fear that we have fallen into the habit of draining every wound without thinking whether it is necessary to drain or not.

I was first led to question the propriety of draining every large wound by the annoyance occasioned by rubber drainage-tubes after operations upon tubercular joints. I found that the sinus caused by the drainage-tube almost invariably became infected and prolonged the case unnecessarily. Although I still drain in cases of this kind when there is a possibility that I may have overlooked some focus of disease, I never use rubber rubes, but use strips of iodoform gauze. In excision of the knee-joint my happiest results have been in cases where I have omitted drainage altogether, or have used a few strands of catgut. I get more satisfactory results after amputations, after operations upon breast and axilla, and, in fact, in all clean-cut wounds, without drainage than with it. No one prizes drainage more highly than I in proper cases, but it is not necessary in an aseptic wound. Those who do not work antiseptically must always

drain, because blood and serum when not protected from germs will surely putrefy in a wound, where all the necessary auxiliaries are found. The most zealous advocates of drainage are those who denounce antiseptic surgery.

It would be amusing were it not such a serious matter to see how zealous a dirty surgeon is in the matter of drainage. He usually carries his rubber tubing in the bottom of his satchel, after taking it from a dusty drawer in his office, and if he has not infected his wound earlier in the operation, always does so when he introduces his tubes.

When carbolic acid was so extensively used drainage was always necessary, on account of the excessive discharge caused by the acid. Lister, in his address before the last International Medical Congress, said that it would be a grand thing if we could do away with drainage altogether, and cited an instance in which he uses but one tube of moderate caliber, where he formerly used four of various dimensions. He speaks of the time when we shall have found drainage no longer necessary as the fulfilment of his early dream. If this great benefactor lives out his expectancy, I feel certain that he will see this day. The enemies of antiseptic surgery point to these advances of Mr. Lister's as evidence of its decay. But every fair-minded man knows that there has been no change of principles.

With all its perfections antiseptic surgery is far from being perfect yet, and many changes of detail are necessary, but these changes instead of being evidences of decay are certainly advances.

As Mr. Lister suggests, these advances are all in the direction of the hermetic sealing of wounds, and this is certainly the ideal method, as it is Nature's method. The hermetic sealing of wounds has been faithfully tried in the past, but the trial was made at a time when the principle of wound infection was undiscovered, and it was necessarily a failure.

Mr. Tait, in his criticism of Mr. Lister's address, claims everything for drainage. He says that when all decomposable material is removed by drainage, germs may be admitted freely. He states that the exclusion of germs is an impossibility, but does not seem to understand that perfect drainage is also an impossibility.

Prof. Erichsen, in some recent remarks upon this controversy, has certainly sounded the key-note when he cites the fact that two elements are necessary for putrefaction in wounds, viz., putrescible material and infective germs, and says that the disputants accomplish the same end by different means: Mr. Tait by removing the pabulum, and Mr. Lister by filtration of air and by germicides. He very wisely asks: "Is it wise to be exclusive in the employment of one or the other of these methods?"

I am certain that many wounds have been infected through the drainage-tubes because it was impossible to keep the ends of the tubes covered by the dressings. I have found it very difficult to keep the dressings close to the wound after radical operation for hernia, and have gotten much better results since I began to apply small strips of iodoform gauze with collodion.

In some operations upon bone and in Phelps's operation for club-foot, special effort is made to secure a blood-clot in the wound, in order that it may become organized. Ordinarily, however, it is important to stop all hemorrhage before closing a wound that we do not wish to drain.

Hematemesis in Gastric Ulcer.

In a very interesting paper on gastric ulcer—part of which is published in the *Medical Chronicle*, February, 1891, Dr. Dreschfeld, of Manchester, England, says hematemesis is one of the cardinal symptoms, and occurs in about one-third of all the cases. It may occasionally be one of the first symptoms, and it does not so rarely happen, especially in elderly patients, that hematemesis comes on in apparently good health. He has seen three such cases within the last eighteen months. In these cases large quantities of blood are vomited, sometimes even clots, and melena soon follows. In cancer of the stomach hematemesis is, he believes, never the first symptom, and if in cases of doubtless cancer, the history shows that hematemesis was one of the first symptoms, we may, he thinks, assume that we have to do with cancer implanted on an ulcer. This was seen in two cases under his care in the Infirmary, and in one case under the care of his colleague, Dr. Leech, as revealed by the *post-mortem* in these cases. In cirrhosis of the liver, and other diseases causing obstruction to the portal circulation, hematemesis may be the first or a very early symptom of the disease; but the history of the case, the presence of symptoms point-

ing to alcoholism, and the appearance of the blood, which is quite liquid and dark colored, help one in the diagnosis. Moreover, as the blood in these cases is venous, the hematemesis is rarely followed by intense anemia, and symptoms of depression. The hematemesis in these cases acts more like a venesection, and the patient after the attack often feels easier than before. The hematemesis in hysteria occurs chiefly in the morning; is, as a rule, small in quantity; and is, as we know, often due to various artifices which the patient has recourse to. This is, however, not as often the case as is generally supposed; and as spontaneous hemorrhages do occur in hysteria, there can be no doubt that in some cases the blood is really derived from the stomach. The presence of other symptoms of hysteria, such as hemi-anæsthesia, globus hystericus, hysterogenic zones, contraction of the field of vision, and so on, are important aids in the differential diagnosis. Such rare cases of hematemesis as those due to the bursting of an aneurism into the œsophagus (the bursting of an aneurism into the stomach is extremely rare) are quickly fatal, whilst hematemesis from an ulcer is after all rarely followed by death.

When hematemesis is not the first symptom, but occurs, as it often does, only during the course of the disease, then the other symptoms of ulcer such as localized pain and vomiting, precede it, and the diagnosis is not difficult.

The vomited matter in hematemesis from gastric ulcer has occasionally the character of "coffee-ground vomit," which is generally looked upon as characteristic of cancer of the stomach. This occurs at a late period of the disease, and is due to a slow and gradual extension of the ulcer, whereby only minute blood-vessels become eroded, and the small amount of blood altered by the gastric juice assumes this peculiar appearance. The vomit is by itself not to be distinguished from that of cancer, but the other symptoms present help to distinguish the one disease from the other.

Profuse hematemesis in gastric ulcer occurs more especially when the ulcer is situated at the pyloric end of the stomach, and more on the posterior than the anterior surface; this is due to the arrangement of the blood-vessels. From this follows two important considerations: First, when in gastric ulcer we get profuse hematemesis, we have, after a time, from the cicatrization of the ulcer, contraction of the pylorus, giving rise to symptoms of dilatation of the stomach. Second, the ulcer gradually extending in depth causes, from its position on the posterior wall, adhesion between the stomach and pancreas, and perforation of the ulcer in these cases is not likely to happen. It is different when the ulcer is situated on the anterior wall, the extension of the tumor in depth is not likely to lead to any adhesions, for the constant movement of the abdominal walls would hinder any such adhesions to form, and hence the frequent perforation of such ulcers; the same holds good if the ulcer extends towards the lower curvature. We can thus understand that perforation is more apt to occur in those cases where there is no hematemesis, or only slight hematemesis, and where symptoms of pyloric constriction are absent.

Open Operation for Strangulated Hernia.

Dr. Benjamin T. Shimwell, in the *Medical News*, March 14, 1891, says:

The classical operation for strangulated inguinal hernia has only partly met the requirements. The advance made in surgery, more especially in that of the abdomen, has allowed a greater liberty of action, which seems not to have been properly taken advantage of in the treatment of this condition. This paper is written to show the advantage gained by the open method of operating—that is, cutting directly through all the tissues of the tumor, including the external ring, internal ring and, if necessary, the abdominal wall, converting a simple herniotomy into a hernio-laparotomy. The condition of the protruding gut is modified by its pre-existing condition, the size of the protrusion, the length of time of strangulation and the position of the constriction. An old incarcerated hernia with a sudden increase of the protrusion and consequent constriction gives an abnormality in relation of structures and their component characters, that has no resemblance to an acute case and causes a difference in the ultimate results of treatment. The size of the protrusion is not so much a factor in causing constitutional symptoms as is supposed. I have seen as violent symptoms in a small protrusion as in one of greater size.

The length of time of constriction also modifies structural capacities, and directly influences the result. The point of constriction may be at either the external or in-

ternal opening, or, what is often overlooked, the true constriction may be the neck of the peritoneal sac, the inguinal rings acting merely as a barrier to the return of the gut and not as a true constrictor.

A careful consideration of these propositions opens a field of thought that must of necessity show the inefficiency of the nicking of the external ring from below. The extension of the incision cannot be said to complicate matters by increasing the risks. It is settled beyond peradventure, that careful increase of a few inches in the length of an incision, whether in the abdomen or anywhere else, does not increase the risks.

Compare the old method with the certainty of work and view of field, the definite knowledge of conditions of the injured gut, and the lessening of risks which were due to handling of gut by the drawing down preparatory to reduction. Would an abdominal surgeon operate in a case with marked adhesions through an opening of the same size that he would in a simple uncomplicated oöphorectomy? Working in the dark is prolific of bad results. It is not in the power of any man who operates for strangulated hernia by the old method to tell with certainty the condition of the bowel, and thus it is that many cases end in death by inflammation of, or ulceration and necrosis of the bowel at the point of constriction. The condition of the congested bowel is the point always to be regarded in determining whether it will regain its normal state. To me it seems that not enough importance is laid upon the condition of the tissue at the point of constriction. There is often an amount of injury done that causes the most serious results. There is the question of necrosis, which is one of importance, and then also the loss of nerve vitality by constant constriction, which is often marked. I have seen this persistent at the end of days, the obstruction still remaining.

Paralysis of a portion of the bowel prevents fecal circulation; the bowel forces its contents to this point, and then is unable to send them further. Gas and fecal matter will enter a paralyzed portion. Continuous action is a necessity. As a proof of this point, a patient upon whom I had performed hysterectomy died suddenly from tympany produced by obstruction of the bowels due to paralysis. The case was one in which every means were tried to relieve the condition. The *post-mortem* examination disclosed the point of paralysis in the lower portion of the ileum. The bowel walls were flaccid at this position for about two inches. Above this the whole canal was enormously distended, while below to the anus it was entirely empty. Experiments on dogs have shown the same results.

It is in the ability to appreciate these conditions properly that the open incision has its strongest advantages. A full inspection of the injured bowel indicates the treatment where special conditions arise, as does the question of resection when gangrene is imminent, or in those cases in which it is apparent that the point of constriction will not regain its tone. The importance of resection in the latter cases has been impressed upon me by the condition of those that I have seen. This loss of tone is apt to be present in old incarcerated hernias, in which narrowing of the canal by pressure has altered the structure of the walls, and in such cases the increased constriction has injured an already impoverished part. Another advantage is the certainty of the complete return of the protruded gut into the abdomen.

The possibility of a radical cure is to be considered. I have one case that I operated on nearly two years ago, which seems to approach a radical cure. This was a case of true hernio-laparotomy. The internal ring was carefully sewn together, the floor of the inguinal canal was curetted and closed by buried sutures which included the external ring, the superficial surfaces continuous with the abdominal wall being brought together with silkworm-gut. The abdominal cavity was cut off at once and coaptation was so perfect that it tolerated the patient's tearing off all his dressings, walking down stairs and sitting on the front steps in the early morning of the fourth day. When I last saw him he was doing active work and was not wearing a truss.

The closing of the canal can be done, if so desired, by retention of the sac in the upper portion of the canal, using any of the methods suggested. In old incarcerated cases the adherent sac can be separated from the surrounding tissues, leaving a good surface for union, while the sac can still be retained at the internal ring, its serous surfaces simply in contact, or by the purse-string method. The open treatment, the value of which is still doubtful, can be tried. If the abdominal walls have been divided, care must be exercised to bring into apposition the peritoneum and transversalis fascia, also the superficial fascias that make Pou-

part's ligament. The latter procedure is a necessity for strength, the sutures entering well into the pubic side to hold the divided ligament firmly together. If this is well done, when union has taken place the ligament can be readily defined and its relations are found to be continuous. Drainage of the pelvis is a necessity if exudation is apt to occur.

Extracts from Tubercule Cultures.

In a paper read at the Boston Society of Medical Sciences, January 27, 1891, and published in the *Boston Medical and Surgical Journal*, February 19, Dr. J. A. Jeffries says: I thought it might be of interest to report a few of my results with extracts of pure cultures of the tubercle bucillus. I began a year ago to make extracts and study their effects on guinea-pigs, my ultimate object being to produce immunity or find some form of treatment. At first I used alcohol (absolute and dilute), ether, chloroform and benzole, and found that my results were very variable, not regular. After this, in the early part of last summer, I began to prepare glycerine extracts, reasoning from the power of glycerine pepsin extracts. With glycerine I soon found that more or less definite reactions could be produced by large doses in healthy guinea-pigs. There would be swelling at the point of injection, evident discomfort, an increase of urine and at times fever, etc.

Owing to sickness in my family nothing more was done until after Professor Koch's first publication. I at once found that my glycerine extracts produced a much more marked effect in tuberculous than in healthy guinea-pigs. The former, after a dose of half a cubic centigram, would in the course of a few hours become very sick, huddle up in a corner with hair on end, shiver, and in some cases pant. Apparently the amount of urine was increased. Tuberculous guinea-pigs, while in the reaction, could be laid down anywhere and did not run away.

All my animals, both those inoculated with the extract alone and those first poisoned with pure cultures of the tubercle bacillus were then put under like conditions to note results as to longevity. Unfortunately a bull-terrier made a raid on my guinea-pigs during the latter part of December, and again on the 8th of January, killed most of my control animals, and thus ruined the experiments as to final results. So that all I can affirm is that some of my glycerine extracts of about forty-five per cent. final strength, allowed to stand at a temperature of 37½° C. for one week, contain a substance which causes a much more marked reaction in tuberculous than in healthy guinea-pigs; and that for two or three weeks after, the former appeared better than the simply tuberculous control animals.

I have not, of course, got far enough to say if such an extract will invariably work, or to what extent it will mitigate the action of the bacilli. Nor do I yet know how old a culture would be the best medium to grow it on, nor if the extract should be made neutral or slightly acidified. I might add that I found no signs of tuberculosis in a guinea-pig which had received one and a half cubic centigram of my extract in divided doses, and was then inoculated with tubercle culture in the abdomen. Too much weight cannot be laid on this, however, as the animal was very badly crushed by the dog eighteen days later—other guinea-pigs inoculated in the same way with cultures died of tuberculosis in about a month.

In closing, I would state that this is only read in view of Professor Koch's latest announcement as printed in the newspapers of January 15, from which I should judge that, working in somewhat the same line and stimulated by his first article, I have got something on the same principle, but am not sure, as I have been unable to procure an atom of the paratoloid for any purpose.

Vaccination in France.

The London Medical Recorder, February 20, 1891, says: The French Academy of Medicine is just now the scene of a struggle between those who are in favor of a law making vaccination compulsory, and the others who think that the present permissive system goes as far as is consistent with personal liberty. The general in command of the "volunteers," that is to say, of those who object to compulsory protection, is no less an authority than Professor Léon Le Fort, and last week he made a vigorous rally from behind his entrenchments, and, with heavy artillery in the shape of arguments, he prevented the further advance of the attacking forces. There are several points in Professor Le Fort's address which merit attention, especially as the matter is at

present under consideration in this country. First of all—and the news will come as a surprise to those who have been in the habit of regarding France as being at the prow of civilization—all statistics based on the mortality-returns, from the different diseases, must be incomplete, and therefore misleading, for the cause of death is only recorded for statistical purposes in the more important French towns, and, presumably, not at all in the rural and smaller urban districts. What the total annual mortality from small-pox in France may be, can, therefore, only be matter of conjecture. Still, the Professor admits that it is certainly higher than it ought to be or need be. Another fact, hardly to the credit of French provincial authorities, is, that nowhere outside Paris is any attempt made to isolate the sufferers from small-pox. He is therefore compelled to fall back upon the Paris returns, and these show that the mortality has been steadily diminishing, from 32 per 100,000 inhabitants, during the period 1865-76; 55 per 100,000 in 1880-7; to 5 per 100,000 in 1889. The returns of the Small-pox Hospital at Aubervilliers testify to the same diminution, the admissions and deaths having been as follows:—

1887 . .	1,400 admissions	. . 215	deaths.
1888 . .	1,079 "	. . 152	"
1889 . .	706 "	. . 63	"
1890 . .	363 "	. . 37	"

There are no available means of ascertaining the proportion of cases of small-pox per 100,000 inhabitants in the country; still less the proportion of deaths to cases of infection. We are, however, told that country doctors have the greatest difficulty in procuring lymph and the people have the greatest difficulty in getting vaccinated, even supposing they were so disposed.

Let us compare these figures with the German statistics. It must be borne in mind that vaccination has been compulsory throughout Germany since 1835, and in some parts since 1815. The returns are as follows:—

In 1834 . .	54 deaths per	100,000	inhabitants.
" 1836 . .	19 "		"
" 1847 . .	9 "		"
" 1856 . .	7 "		"

In 1865, the war led to a relaxation of the stringent rules in respect of isolation, and forthwith the number of deaths from small-pox jumped up to 46 per 100,000, and in the following year to 62. During the Franco-German war, small-pox was imported into Germany by the returning soldiers, and more particularly by the French prisoners of war, and the mortality from variola in 1871 attained 59,839, and 77,000 in 1872, equal to 233 per 100,000 civilians, and 31 per 100,000 of the military population. In 1874, the vaccination law was consolidated, and a vaccination service founded for the supply of lymph, and by 1877 the number of deaths (810 in 1876) had fallen to 88. This level, however, was not maintained, for in 1882 the figures had again risen to 1,007. Thereupon the German Government enjoined more stringent measures for isolation, and then the downward tendency returned, and in 1886 the number of deaths was 140 only.

In England, the mortality in 1885—a time when vaccination had long been in full swing, but when isolation was not seriously enforced—the number of deaths from small-pox in London alone was 1,419. In 1886 the number fell abruptly to 24, in 1888 to 9, and in 1889 to 1 (!). This diminution coincided with the introduction of isolation on a large scale, which reached its apogee with the law for compulsory notification in 1889.

Professor Le Fort argues from these figures that, though vaccination has an undoubted and valuable influence in affording protection and in mitigating the severity of the disease, the most effective and reliable means of preventing the spread of the disease is rigorously enforced isolation.

While it is impossible to deny the salutary influence of isolation, it seems a trifle inconsistent to object to vaccination as an infringement of the liberty of the subject, while rallying to the principle of compulsory isolation, which is as directly in contravention of personal liberty as any measure well could be. To take a patient, *non volens*, and shut him up for eight long weeks in a hospital, is surely as obvious an attack on his liberty as to insist on his submitting to the trivial operation of vaccination. This question of personal liberty, unfortunately, does not admit of any categorical reply. Different people have different ideas as to what constitutes liberty, and as to what limits, if any, are to be assigned to its play. Still, the great object that we have in view, is to secure cheerful submission to an infliction imposed by reason rather than by law, and if this could be attained by persuasion, instead of coercive legislation, then the choice would be easy.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

PRESBYTERIAN HOSPITAL IN PHILADELPHIA.

An event of unusual importance occurred in Philadelphia January 15, when the Presbyterian Hospital of this city celebrated the completion of its new administration building. With this gift of a rich and generous citizen of Philadelphia—and the filling out of a series of gifts, some very large and some smaller—the Hospital has come into the possession of a magnificent series of buildings, fitted with every appliance necessary for a first-class hospital. In many respects, it might be taken as a type of what is best in the development of the Hospital idea in this country; and happily it is only a type of many similar institutions which, bearing the name of some denomination of the Christian Church, extend their charity to all sufferers of every name and every condition.

The benevolence and the beneficence of institutions like the Presbyterian Hospital can hardly be over-estimated. Medical men, more, perhaps, than any others, know how far-reaching is the good done by gifts to such an object. Those who live in cities know especially how great is the difference between what can be obtained by the sick and injured poor in their own houses, and what they get in such a Hospital as this, as well as how much to them it is to be spared the painful alternative of staying at home or going into the Almshouse Hospital, no matter how well that may be managed—as is the one in this city. For this reason, we may be glad that the Presbyterian Hospital in Philadelphia has been so prosperous, and seems likely to be more prosperous and more useful as time goes by.

PATHOGENESIS OF TETANUS.

The immense strides made in the science of bacteriology during the few years of its existence and development are well illustrated in the study of the etiology and pathogeny of tetanus. In 1885, Nicolaier demonstrated that fatal tetanus could be produced in mice, guinea-pigs and rabbits by subcutaneous inoculation with superficial layers of earth, a slender bacillus being found both in the earth and at the site of inoculation. In 1886, Rosenbach found the same bacillus in wounds in man in cases of tetanus as a result of injury or of extreme cold, which reproduced the disease in inoculated guinea-pigs and mice. It was not, however, until 1889 that Kitasato, in the laboratory of Koch, succeeded in isolating and cultivating the bacillus, while but a few weeks ago from the same source emanated an announcement as to the conferring upon guinea-pigs of immunity against tetanus.

Le Bulletin Médical, February 1, 1891, contains a highly interesting paper on the pathogenesis of tetanus, by Drs. Vaillard and Vincent, presented at a meeting of the Académie des Sciences, January 26.

Inoculation of animals with pure living cultures of the bacillus of tetanus is always followed by tetanus, but, contrary to what is observed in men and animals spontaneously infected, the pathogenic agent does not multiply at the site of inoculation in the blood or in the organs of the body. This peculiarity is in apparent contradiction to the prevailing notions concerning diseases of parasitic origin, the evolution of which is correlative of the pullulation of the pathogenic organisms. The explanation lies in the fact that inoculations of cultures of the bacillus of tetanus are active only by the presence of the toxine which they contain. The animals succumb to the intoxication produced by the poison elaborated by the bacilli, and not as a result of the growth and development of the organisms in the tissues. This may be proved in two ways. If a number of animals are inoculated with a living culture, and an equal number with the same dose of the culture sterilized by filtration through porous earth, all die after the same interval. If, on the other hand, a susceptible animal, such as the guinea-pig, be inoculated with even considerable quantities of pure cultures of the bacillus of tetanus, deprived of all traces of toxine, tetanus does not develop. Thus, the bacillus or its spores in a state of purity, without toxine, does not produce tetanus when injected into the tissues of a healthy animal, but the animal dies if inoculated with the products secreted by the wound in a patient having tetanus or contained in tetanigenous earth. These results are not contradictory, but depend on conditions which favor or retard infection.

If an ordinary micro-organism, such as the bacillus prodigiosus, be associated with the spores of the tetanus bacillus, freed from toxine, tetanus can be provoked. Another means, not less certain, is to expose an infected wound to the impurities of the air. This can be demonstrated by introducing beneath the skin a small bit of sterilized cotton, impregnated with some spores, freed from toxine. The wound is soon invaded by adventitious microbes and may suppurate. Fatal tetanus soon supervenes. We have here reproduced the conditions of natural infection. Light is thrown on the part played by the association of micro-organisms in the pathogenesis of tetanus. A new point in the history of diseases of parasitic origin is established.

The activity of the pathogenic germs already known is greatest in their pure state. The primary condition in experimental study, hitherto, has been the perfect isolation of the virus, and its inoculation in a state of absolute purity. This is not the case with tetanus. The pure virus is without effect. Impure, however, it is pathogenic.

The microbe of tetanus is incapable of vegetating in the tissues of a healthy animal, but it pullulates if simultaneously another microbe, which may or may not be pathogenic, is introduced with it. This explains the tetanigenous power of earth, rich in microbes of many species, all of which, however, do not favor the development of the bacilli of tetanus in wounds. Other conditions may facilitate infection. Thus, tetanus may be produced by inoculating an animal even tolerably resistant with a mixture of spores, without toxine, and a solution of lactic acid or a few drops of trimethylamine. The action of certain chemical agents upon the tissues is favorable to the development of the germ, which, without this association, would be inactive. The result is the same if the spores are introduced into a contused muscle. The bacillus of tetanus or its spores does not provoke tetanus in a healthy animal, when injected in a pure state, without toxine, because of the action of certain cellular elements or phagocytes. This may be studied in the anterior chamber of the eye or in the subcutaneous connective tissue. Interference with the protective action of the phagocytes favors infection. Thus, lactic acid repels the afflux of leucocytes, permitting the

spores to vegetate and the bacilli to elaborate their toxine. The bacillus prodigiosus, on the contrary, attracts the leucocytes, engages their activity, diverting it from the tetanus spores, is taken up by them, while the dangerous agents germinate and secrete the fatal poison. In the case of natural infection the phagocytes are able to exert their prophylactic influence only at the beginning of the conflict with the invading microbes. Finally, as the bacilli elaborate their toxine, the phagocytes are overcome.

TRAUMATIC NEUROSES.

In connection with the case of traumatic neurosis published in the REPORTER, March 21, 1891, it is interesting to note that Bitot and Lamarque, residents of the Hospital of Bordeaux, reported, according to *Le Progrès Médical*, February 14, 1891, a case of what they call hysteria in a man, after a fall into the hold of a vessel—a distance of over sixty feet. The attack began with disturbances on the side of the face, which were rather hard to understand, but it developed as glosso-labial hemispasm, or hysteria. He had also habitual stigmata, hemi-anasthesia and contraction of the field of vision. The patient fell upon some casks, which he struck hard with his heel. This was soon followed by hyperesthesia in the heel, which was attributed to hysteria. An interesting feature of the case is the fact that the hysterical manifestations disappeared in a few months, which does not often happen in traumatic hysteria, and that the patient was a person predisposed to manifestations of this kind, having had nervous ancestors, and having, himself, always been an odd and excitable man.

Recent investigations on this subject will probably throw some light upon the strong and only obscurely-understood manifestations of nervous disturbances after railroad accidents, and accidents which simulate railroad accidents in their principal features. Some difficulty in these cases is experienced from the fact that many of the cases have associated with them a moral element, depending upon the possibility of securing damages from corporations in proportion to the real or apparent severity of the consequences of the injury; but those who have studied the subject carefully seem to be practically unanimous that violent physical shocks make some impression upon the nervous part of the human system, which may show itself in very remarkable ways. Dr. Shipps's case in the REPORTER—referred to above—was regarded as one of temporary insanity, and so, no doubt, it was in one sense of the term; but a more careful classification would probably place it with what are now called traumatic neuroses. Many such cases have been reported recently, and when attention is generally attracted to the way in which the subject is now regarded, it is probable that more will be put on record, and that the means for securing a good understanding of the matter will be increased.

EXCISION OF CHANCRES.

The distinct and different individuality of chancre and chancroid is a comparatively modern doctrine, but it is, to-day, almost universally accepted. There are, however, some prominent syphilographers who still claim the unity of these two lesions, so that any observations in regard to them from reliable sources are worthy of careful consideration. Since about fifteen years ago it has been believed, by certain syphilographers, that early excision of the chancre will prevent the subsequent development of syphilis. The determination of this point is a matter of the highest therapeutical importance. The *Centralblatt für die Medicinischen Wissenschaften*, January 10, 1891, contains an abstract of a paper by Neumann, the eminent syphilographer and dermatologist of the Vienna University, in which he details the results of auto-inoculation of syphilitic patients with the secretion from the primary lesion. If, in from

three to five weeks after infection, inoculation with the secretion of a non-suppurating chancre is followed by any result, which is not always the case, there appears in the course of a week a circumscribed redness which develops into a papule shortly before the appearance of constitutional manifestations. The papule grows larger and firmer with the progress of the eruption, recedes with this, following the course of an ordinary lenticular papule; while the primary lesion grows smaller and softer at the time the eruption appears. Nor does the inoculation-papule, like the chancre, occasion swelling of adjacent lymphatic glands or give rise to the development of firm lymphatic cords or to the formation of crater-like ulcers of cartilaginous hardness. These papules cannot be considered identical with the primary lesion, but as manifestations of constitutional syphilis, as the result of irritation, to which syphilitic subjects react with peculiar readiness. If the inoculation is made with the pus of a chancroid, in three days a pustule forms, with an erythematous areola, beneath which a deep ulcer appears, the base of which becomes indurated in a degree in proportion to the intensity of the infection. The same result, however, may be obtained with the pus from the pustules of acne, eczema or scabies.

The conclusion to be drawn from these observations is that syphilis cannot be aborted by excision of the primary sore. Results of a positive nature, as published, must depend upon errors in diagnosis.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

GUIDE TO THE PRACTICAL EXAMINATION OF URINE. By James Tyson, M. D., Professor of Clinical Medicine in the University of Pennsylvania, etc. Seventh edition, revised and corrected. 7½x5½ inches, pp. 255. Philadelphia: P. Blakiston, Son & Co., 1891.

The unimpaired popularity of Dr. Tyson's book on examination of the urine is demonstrated by the regularity with which one edition follows another. This popularity is both deserved and insured by the fact that to the original merit of the book has been added a constant care to keep it fully up to the state of knowledge in regard to the subject, so that each new edition is better than the last. The result is that the book is without an equal—we believe—in the English language for usefulness to students and practitioners. For the former it is almost a necessity, and for the latter it may be a most valuable aid.

In spite of the advanced teachings now given on urine analysis and examination in the first-class medical schools, there are still many physicians who know almost nothing of the subject and who might profit very much by getting and studying a plain and practical book like the one before us. To such physicians and to all students we heartily recommend Dr. Tyson's admirable manual.

POST-MORTEMS; what to look for and how to make them, with sections on Infanticide, Poisons, Malformations, etc. By A. H. Newth, M. D., London. Edited, with numerous notes and additions, by F. W. Owen, M. D., Demonstrator of Anatomy in the Detroit College of Medicine. 12 mo, pp. 136. Detroit, Mich.: The *Illustrated Medical Journal* Co., 1885. (?) Price, $1.00.

This little book begins with directions for the external examination of the body, then follow sections on signs of death from violence, poisoning, etc., and on the internal examination of the body. The latter section is naturally divided into sub-sections containing directions for the examination of the organs of circulation, respiration, digestion, etc., and brief descriptions of the *post-mortem* appearances of the organs and tissues in disease.

The book contains a large amount of useful information, but the matter is so condensed and the descriptions are so brief, that one gets from reading them no helpful picture of pathological anatomy, and no insight whatever into disease-processes as they appear after death.

Literary Notes.

—F. C. W. Vogel, the well-known publisher of Leipzig, announce the appearance at this time of a new journal of neurology called the *Deutsche Zeitschrift für Nervenheilkunde*, six parts to make a volume and to cost about 15 marks. The editorial management is to be in the hands of Drs. Erb, Lichtheim, Schultze and Strümpell. Their preliminary announcement indicates that the new journal will be conducted upon lines which cannot fail to make it a most valuable addition to medical literature.

Notes and Comments.

New Method of Treating Enlarged Prostate.

In a paper published in the *Edinburgh Medical Journal*, March, 1891, Dr. Marotti said: To effect a cure of ischury from prostatic strictures one must understand and meet the diseased condition which produces the enlargement. In prostatic strictures the ischury is occasioned by a mechanical ob-

stacle to the emission of the urine. Now, the therapeutic direction must follow two indications—*Firstly*, To increase the expulsive power, so as to overcome the obstacle; *Secondly*, to remove, or at least to lessen the obstruction, so as to restore the regular passage of the urine. The surgeons of all times have endeavored to carry out the second, rather than the first, of these two questions, and have thought of many different ways. The apparatus invented by Dr. Bottini, of Pavia, completely carries out the idea of making an artificial passage for the urine in the body of the same prostate. The passage of the urine being restored, hypertrophy of the prostate does not any longer entail danger to life, therefore it is useless to take away an organ which, although abnormally enlarged, yet does not affect the general work of the entire body. The therapeutic idea is not that of melting or otherwise destroying the prostate, but that of making a new passage for the urine, to replace the passage which has been obstructed by the abnormal enlargement of the gland. The way of fusion and incision of the prostate by thermo-cautery in such conditions seems rational both as to its immediate effects and as to its ultimate consequences. We need not only to divide the prostatic growth, as the prostatic incisor of Mercier does, but also to keep it open, making at the same time an aperture inside, which will not be quickly closed up, but leaves a permanent groove through which the urine can flow.

The instrument of Dr. Bottini resolves the problem of the practical application of such an idea. The problem was how to heat a certain portion of the instrument, so as to bring it in front of the diseased enlargement which is to be treated, limiting the caustic effect to burn a particular spot, without injuring the urethra and the bladder.

After long and diligent experiments on dead bodies and on living animals, Dr. Bottini succeeded in making an instrument which answers thoroughly the object proposed. The "cauterizatore termo-galvanico"[1] is composed of a metallic tube resembling the catheter of Mercier, internally divided into four compartments for the passage of the conducting electric wires, and the tube for the water, which, entering into one of the canals, runs to its extremity, then passes to the other canal and flows out at the free end, keeping the whole instrument at a constant low temperature. The conducting wires end in two little plates, one-third of a centimeter broad and two centimeters long, placed parallel to each other at a distance of one millimeter, and joined at the bow towards the beak of the instrument, from the curve of which they are separated one centimeter. These plates must get heated to a dull red, the only color which insures destruction of the tissues without causing a single drop of blood. The flow of cold water, keeping all that part of the instrument constantly cold, so that it may not have a caustic action, prevents the epithelium and the mucous membrane of the bladder from being injured, while cauterization of the part of the prostate is being effected.

It is always better to accustom the patient to the use of the instrument before the cauterization, so that its introduction may be easily and quickly done, and the enlargement may be reached at once by applying the cautery exactly to the designed spot. The rule of accustoming the urethra to the passage of the "cauterizatore," so that the instrument may slip by its own weight into the bladder, as Civiale happily expresses it, "C'est l'urethre qui doit avaler la sonde," and so that we can bring the heated portion against the part to be destroyed, is of vital importance. As the patient has been placed in the position used for lithotripsy, unless the bladder be completely empty, we need not inject water. The operation is not painful. Dr. Bottini uses chloroform only occasionally; nevertheless we must insure that the patient will be kept still during the operation, otherwise by a sudden movement the instrument might get displaced, and come against parts which ought not to be touched.

The operative technique consists of three parts:

Firstly, We introduce the instrument, and place the cautery against the part of the enlarged prostate to be burned.

Secondly, We get the cautery heated, and we cauterize to a sufficient degree.

Thirdly, We withdraw the instrument.

In regard to the first, we introduce the instrument into the bladder according to the classical rules prescribed in urethral catheterism. Then we must turn down the beak, as we do in the methodic exploration of the fundus of the bladder, and pulling the shaft so as to hook the neck, we may carry the cautery against the proper spot. If any doubt arises, the position of the instrument

may be ascertained by a finger introduced into the rectum. The instrument being properly placed we allow the water to come in, which can be done by suspending a common pail, or an irrigator of Esmarch, at a certain height, capable of holding six or eight liters of water, at a temperature of about 40° to 50° Fahrenheit.

The battery which Dr. Bottini uses is a Bunsen's, with two liquids, in the improved manner of Pischel, and lately again improved by Dr. Bottini, by the introduction of the accumulators, as he has fully described in his article in the *Lancet* of September 20.

The heating of the cautery must not exceed the dull red; if it does exceed this, and becomes white, the tissues will be too quickly destroyed, and most probably hemorrhage will ensue.

With repeated experiments on dead bodies and on living animals, Dr. Bottini obtained, in one minute, by the cautery being heated to the red color, an eschar about the thickness of a centimeter, and the action being prolonged for another minute, the thickness has become doubled, when he could raise the temperature by one degree, changing the commutator of the battery.

To insure the eschar being formed as indicated, the heated portion of the instrument must be placed against the part to be burned, raising the shaft and bending it gradually, so that the resistance of the diseased tissue having been overcome the beak can be embedded in it. We must then stop the further production of heat by shutting off the current, and let it remain for two or three minutes, so as to give time for the plates to cool, so as to render harmless the withdrawal of the instrument, which will be done in a manner the reverse of that used when it is introduced. We do this in order to prevent the risk of the eschar being brought away with the withdrawal of the instrument.

For the after-treatment we use the soft catheter of Nelaton, always provided that the patient cannot pass water by himself. Dr. Bottini wrote me that a few days ago he had to operate on an old man, suffering from prostatic ischury for more than five years, who after twenty-four hours from operation was able to pass water without artificial assistance. The eschar is completely gone by the tenth, twelfth or fifteenth day.

Dr. Bottini has operated after this method on fifty-seven cases, two of which ended fatally; these, however, were during the early days of the operation, before the instruments had been brought to their present state of perfection. In thirty-two cases a perfect cure had been obtained, in eleven there was an improvement, and in only twelve was no benefit observed. These results in an affection which was so rebellious to ordinary treatment, form a powerful argument in favor of the method; and the author hoped soon to see it adopted more generally by surgeons than it had yet been.

Who Owns the Prescription?

In a paper on the subject of prescription ownership, read before the Philadelphia College of Pharmacy at the Pharmaceutical Meeting, January 20, and published in the *American Journal of Pharmacy*, February, 1891, Mr. Joseph England asks: To whom, then, does the prescription legally belong? To the physician? Certainly not. He has been paid for all services rendered. To the patient? No; for in his recovery to health he has received all that he paid his medical adviser for. To the pharmacist? Yes; by every right of custom and law, provided he has accepted it under certain conditions. If the patient makes a request for its return on presenting it, the pharmacist has one of two lines of action before him. He must either refuse to compound it under such conditions, or express a willingness to compound it and give a duplicate copy. If the latter proposal be refused, he should return the original prescription without compounding. On the other hand, if the prescription is committed to his hands with no primary request for its returnal after being filled, and he has affixed his marks of identity and compounded it, he should retain the original copy as legal evidence that he has prepared such a prescription.

As showing the legal value of a prescription it may be of interest to state that Mr. Robert England informs me he has been subpœnaed in three cases within the last three years to produce certain original prescriptions for the purpose of: 1, to prove attendance in a suit for medical services. Suit was won. 2, to prove that a physician used drugs for malpractice. Physician convicted. 3, to prove that a medical student illegally practiced medicine. In this latter case, the patient dying and the student being unable to give a certificate of death, the

case was examined by the Coroner, and when confronted with the prescriptions confessed guilt. In each instance, however, the legal authorities returned the prescriptions, thus tacitly admitting their ownership.

But this whole question of prescription ownership, to my mind, is essentially one of law, and viewing it from that standpoint, it presents some most interesting features. I have been fortunate in securing for this afternoon's meeting an expression of opinion from that eminent authority on civil law, Richard C. McMurtrie, of this city. He writes me as follows:

BULLITT BUILDING, January 15, 1891.

Dear Sir: You ask who is the owner of a prescription, the physician who writes it, the patient for whose use it is written, or the apothecary to whom it is handed to compound?

Evidently the only dispute can exist in a case in which the physician and the patient have parted with the possession of the paper, and it has lawfully come into the hands of the apothecary, at the instance of the patient.

The universal practice appears to me to point where the title is for all purposes but one. I presume it is the custom to refill a bottle with a prescription indicated on the label. The patient is not required to purchase a new prescription every time he wishes the order filled—and this appears to me plain, from the consideration that he could secure this by copying the paper before using it.

Moreover, he has paid for the composition and skill required for that purpose, and the delivery to the apothecary is for a particular object, and there is in that transaction nothing implying a transfer of property in anything by the patient to the apothecary.

But the practice certainly is for the apothecary to retain the documents. I presume no one ever heard of a prescription being returned with the dose to the patient.

It is obvious there is nothing indicative of a sale or transfer of title on that footing in this transaction. There is something analogous in respect of a check. The return of these instruments arises out of distinct considerations. Accepted bills are never returned to the drawer if paid.

Then there is a consideration which I consider conclusive, seeing that the thing is open to a contract, and the parties have chosen to make none. If under this view of the case the usage is not of itself conclusive, I think the apothecary has the right to retain, to warrant himself, if a question shall arise, as to correctness of conduct.

I may add the claimant must always show his title—if the title be in equipoise he must fail.

It also occurs to me that this paper is merely a substitute for a verbal direction, and no doubt there are multitudes of verbal orders filled that might be written.

On the whole, I should think there ought to be no doubt that the apothecary may, if he sees fit and is foolish enough to run the risk, put the paper in the fire. There can be no half-way measure—he either owns it absolutely, or not at all. There can be no duty to produce it for inspection, or to give copies, while it would be silly to refuse to do so when reasonably demanded.

It is very unusual in this country to look to the consequence of a rule. It may be well to do so. If the patient is the owner—he may at any time within six years demand the paper, and if it is not surrendered, sue as for a tortious conversion of his property. If he can't do this he certainly has no title. I would ask if executors ever inquired for prescriptions given the testator; if they belong to the testator, they are assets.

R. C. MCMURTRIE.

Paroxysmal Tachycardia.

Dr. H. C. Wood, in the *University Medical Magazine* for March, presents the history of a case, in a physician, of a perplexing cardiac disturbance to which he has attached the name, tachycardia. The affection is one of several forms of "cardiac nerve storms" which may or may not be associated with organic lesion of the heart; and this lesion, in turn, may or may not be essential—it may, for example, be trophic or secondary to a nerve lesion, as in the cases reported by Teissier, in which the aortic valves were found to be punched out as with a perforating ulcer. Whether this trophic explanation be accepted or not, Dr. Wood has no remaining doubts that there are cases of violent nerve storm, accompanied with excessive pain—nerve storms similar in character to those that constitute the "gastric crises" of posterior sclerosis—in which no lesion of the valves

can be discovered; and these cases differ also from the paroxysms of true angina. Dr. Wood is inclined to restrict the use of the term tachycardia. In accordance with this etymology, it could be made to apply to any case of rapid action of the heart. But he regards it as fortunate that there has not yet been any very frequent use of the word, sufficient to affix to it any settled meaning, and he suggests its limitation to those diseased conditions, marked by violent action of the heart, that are not dependent on organic cardiac disease, or on febrile excitation, or on a general constitutional affection, such as exophthalmic goitre. He proposes the restriction of the name tachycardia to cases in which very violent action of the heart occurs without obvious reason. The greater number of these cases resolve themselves into the following three classes: (1) paralysis, centric or peripheral, of the pneumogastric or inhibitory nerve; (2) cases of reflex disturbance, as from the irritation of a biliary calculus or of the sexual organs in the female; and (3) those in which the affection is a neurosis, as when it is due to hysteria or allied conditions, or to exhaustion from privation, or to fright, or to the too rapid ascent of flights of stairs.

Carrying the distinction still further, Dr. Wood places in a class by themselves certain rare cases of cardiac motor-nerve storms to which he applies the title of *essential paroxysmal tachycardia*, several of which cases have been found by him in the contributions of Nothnagel. In the most striking of these cases, the patient was subject to violent action of the heart that came on abruptly, even during absolute quiet, without marked pain, but with some sense of anxiety. In a moment the pulse would go up to 180, the heart sounds meanwhile remaining normal. The duration of the tachycardial paroxysm varied from a few minutes to several hours. In the instance of the physician, already referred to as Dr. Wood's typical patient, the pulse-rate rises as high as 160 if the patient remains at rest, and as high as 200 if he exerts himself, as in walking. The access of the paroxysm is abrupt, and so is its cessation. During rest the disagreeable sensations belonging to the attack are hardly more than slight pain and a sense of thoracic fulness. The patient, Dr. H. C., is now over eighty-five years of age, and since about his sixtieth year has had these paroxysms, on an average, once in every three weeks, although he has had as many as four in a month. This was his experience prior to 1888; latterly the attacks have been more frequent. The paroxysms may be brief and they may be broken up by some medicament after a few minutes—but various forms of treatment tend to lose their efficacy after a certain number of trials—or may be protracted to ten or even twenty-six hours. The patient has been examined frequently for cardiac lesion by various physicians of high rank, both during the attacks and during the intervals, but at no time has any murmur been found. His health has continued good, and now, in his eighty-seventh year, he continues to be sufficiently vigorous to be able to ride about in his carriage for hours at a time, and even to walk considerable distances. The attacks have become very frequent, occurring during the last year almost every day, but they are often terminated promptly by the drinking of a glass of cold water. The pulse now rarely rises above 135, there is little distress, and he can even write a letter in the height of a severe paroxysm without the handwriting showing any tremulousness or otherwise giving evidence that it is the work of a tachycardiac old man.

In conclusion, the following is Dr. Wood's definition, given in his own words, of essential paroxysmal tachycardia: "The definition of the disease would be that of a recurrent paroxysmal neurosis in which attacks of excessively rapid heart action occur without obvious immediate or disposing cause, and without pronounced pain or excessive cardiac distress, the pulse rising to 160 and upward, the sounds of the heart remaining normal, and it being frequently possible to arrest the attacks by drinking a glass of cold water and certain other procedures of apparently trifling import, the disease having apparently no tendency to shorten life or to develop organic disease, and being entirely compatible with great mental and physical activity." In regard to the influence over this affection of so simple an act as the swallowing of a small amount of cold water—which is probably a characteristic phenomenon of the trouble, since it has been noted in nearly all the fully reported cases—Dr. Wood refers to observations by Dr. S. Meltzer, which show that swallowing is attended with a loss of tone in the vagus centre, and with a consequent cardiac inhibition, but it is also possible

that the swallowing of cold or hot liquid begets a stimulus to the cardiac centre by an irritation of the peripheral gastric filaments, since it is well known that an irritation of the abdominal nerves is competent to inhibit the heart in a reflex way; and the temperature at which the liquids are swallowed is important, since, if the water, when taken by the patient, is only moderately cold, much larger quantities of it are required.—*New York Medical Journal*, March 14, 1891.

Open and Subcutaneous Tenotomy.

In the *Medical Chronicle*, February, 1891, is an abstract of an article by Sabatier on "Open tenotomy and subcutaneous tenotomy," published in the *Lyon Méd.*, December 28, 1890, which says that since the introduction of antiseptic surgery there has been a tendency to abandon subcutaneous tenotomy in favor of tenotomy by means of an open wound, and that Sabatier discusses the reasons for and against each method, taking in turn the tendons which are most often divided.

The sterno-mastoid.—The reasons given by those who favor the open method are two: The absolute security against accidental injury of vessels, and the ease with which one can obtain complete division. In support of the first reason, three cases of wounding of large vessels, such as the internal and external jugular veins, are quoted. In addition, abnormal vessels may be injured. In support of the second reason it is argued that there are various forms of torticollis, the most simple being limited to contraction of the sternal head of the muscle. The clavicular head is, however, almost always affected, and in the more complex forms the levator anguli scapulæ, splenius, trapezius and scalenes. There are also fibrous forms affecting various parts of the cervical fascia. It is in these cases that subcutaneous tenotomy is both incomplete and dangerous.

In reply to these reasons Sabatier contends that the dangers of subcutaneous tenotomy have been exaggerated, and that the open method is unsuitable.

Out of the thousands of subcutaneous sections of the sterno-mastoid only a few cases of wounds of large vessels are known, although he admits that perhaps all have not been published. All danger may be averted by entering the knife at the internal border of the muscle, and fifteen to twenty millimeters above the clavicle, to avoid the horizontal part of the anterior jugular vein as it runs beneath the muscle to join the external jugular. The knife edge must then be turned against the deep surface of the muscle, and the division itself effected by pressure, and not by sawing movements of the blade, counter pressure being made with the thumb on the external surface. By this method of division from behind forwards only the deep aspect of the skin is in danger; if performed from before backwards the vessels may be injured. He therefore concludes that in ordinary cases subcutaneous tenotomy of the sterno-mastoid is not more dangerous with regard to immediate accidents than open tenotomy.

The great inconvenience of the open method is the cicatrix left in an exposed region. Even if it be smooth, it is generally horizontal, and all horizontal cicatrices are more visible than vertical ones. Moreover, it undergoes vertical displacement from below upwards as age advances, so that it may even reach as high as the middle of the neck. If the wound suppurates, or keloid growth subsequently attacks the cicatrix, it becomes much more unsightly.

For this reason, Sabatier's second conclusion is, that in ordinary cases of torticollis, it is preferable to practice subcutaneous tenotomy. With regard to the very complex cases, he believes that nearly all of them can be cured by subcutaneous section, and subsequent continuous extension by means of some mechanical apparatus, but in very exceptional cases open tenotomy ought to be adopted.

Tenotomies of the lower limb.—These are performed in three regions—at the root of the thigh, on the adductors and the muscles attached to the anterior iliac spinus; at the knee, on the hamstring tendons; and at the foot, on the tendo Achillis, and plantar aponeuroses.

At the root of the thigh.—There are no advantages whatever in open tenotomy here, and the subcutaneous method should always be chosen.

Hamstring tendons.—Sabatier advises open tenotomy for the biceps tendon, because one can better avoid the external popliteal nerve. A cicatrix in this region is not of importance, and the division can be made more complete. It is also best for the semi-membranosus and semi-tendinosus, because of the more complete division and the security

from wounding the deep vessels. Inflammations of the knee-joint often spread to the tissues below the knee, and the vessels get distorted and fixed in unusual positions.

After the operation is completed, he leaves the wound open, and packs it with iodoform gauze; sutures should not be used, because after forcibly straightening the limb, the soft parts are extensively lacerated, and a large quantity of plastic exudation is thrown out, which causes tension and suppuration if the wound be firmly closed with sutures.

Tendo Achillis and plantar aponeuroses.—For the tendo Achillis the subcutaneous method is the best, and the section from the deep surface is the easiest, because the flexion of the foot necessary to make the tendon prominent, also draws it into close contact with the skin, rendering it difficult to pass the tenotome between the tendon and the skin. It is also better to do it from the inner side, because in some cases of club-foot the posterior tibial vessels become tortuous and spread over a large surface, and are thus liable to injury if one punctures from the outer side. Again, in cases of club-foot, the tendon is much more visible and prominent on the inner side, and so more easily divided from that side. With regard to division of the plantar aponeuroses, he thinks subcutaneous section quite sufficient, and condemns the free, open and extensive division advocated by Phelps as being in almost all cases more than is necessary to reduce the deformity.

Laparotomy for Disease of the Liver.

The Paris correspondent of the *Medical Press*, February 11, 1890, says that recently M. Routier related an interesting case of laparotomy for jaundice of a severe type. A nurse in the hospital was seized with severe hepatic colic lasting twenty-four hours. In spite of energetic treatment jaundice set in, the fecal excretions were discolored and the urine almost black. The liver was felt below the false ribs, and the gall-bladder was painful. For a whole month the condition of the patient remained unchanged, and at the end of that time vomiting set in, and the patient became much emaciated. Believing that a biliary calculus was obstructing the bile duct, the surgeon determined to explore the region, and for that purpose laid open the parts by an incision on a level with the inferior edge of the liver. Passing his fingers through the wound he felt the gall-bladder, which did not seem in any way distended, and consequently was not obstructed. He passed his fingers then over the inferior edge of the hepatic organ, but found nothing abnormal. Before withdrawing his hand he felt the head of the pancreas, but no tumor was discovered there. Finally, he closed the wound, and, strange to say, the vomiting, which had been previously uncontrollable, ceased, and in two days afterwards the jaundice paled, and in a week the urine assumed its normal color, and the patient speedily recovered. The speaker could only explain the happy result by the fact that the massage displaced some mucous collections which had obstructed the flow of the bile.

Post-partum Hemorrhage Treated with Caffeine.

Misrachi, in the *Journal de Médicine*, January 25, 1891, recommends the subcutaneous injection of caffeine as more efficient than ergotin in the treatment of post-partum hemorrhage, especially when there has already been much loss of blood, and delay is dangerous. He gives the following prescription.

℞ Sodii benzoatis . . . . . ℥ ijss
Caffeinæ . . . . . ℥ jss-℥ ij
Aquæ destillatæ . . . . . f℥ j
M.

Of this solution, a drachm, which contains twelve and a half or fifteen grains of caffeine, is to be injected at once, and subsequently from a drachm and a half to two drachms and a half in twenty-four hours. The solution should always be employed warm.

To Remove Dark Color from Comedones.

The *British Journal of Dermatology*, February, 1891, gives the following prescription of Unna and Leistokow for removing the unsightly "black-heads" which are so often an annoyance to a patient and a trouble to the physician.

℞ Lanolin . . . . . 10 parts
Vaselin . . . . . 20 "
Peroxide of hydrogen . . . . 20–40 "

WILLIAM R. WARNER & CO.'S

PIL. CHALYBEATE COMP.

IN THE TREATMENT OF

LA GRIPPE.

FORMULA:—Carb. Protoxide of Iron, gr. ijss.
Ext. Nux. Vom., ... gr. ⅓

ADVANTAGES:—Does not constipate, is easily absorbed, is nerve tonic and quickly soluble.

The effects left by La Grippe are marked Physical Prostration for which Pill Chalybeate Comp. (Warner & Co.'s) is almost a specific. The assimilable iron, acting as a blood tonic and the Nux Vomica as a stimulant to the spinal cord.

Dose, begin with one pill every four hours and increase to two pills three times a day.

The acute symptoms of La Grippe are controlled by (**EFF. ANTALGIC SALINE**), one dessert spoonful of which contains 4 grains Antipyrine and 4 grains Salicylate Soda. Physicians will not be disappointed in the treatment of La Grippe by trying this salt followed by PILL CHALYBEATE COMP. as above mentioned.

WILLIAM R. WARNER & CO.,

1228 MARKET STREET, PHILADELPHIA. 18 LIBERTY STREET, NEW YORK.

AVOID SUBSTITUTIONS AND SPECIFY WARNER & CO.

☞ The Coating of PILL CHALYBEATE CO. is Colored a Delicate Pink. ☜

GOUDRON DE BLOUNT

PREPARED FROM THE GENUINE CAROLINA TAR.

DOSE.—One fluid drachm four or more times a day (as indicated), either full strength, diluted, or, in combination.

INDICATIONS.—Chronic and acute affections of the Air Passages, Coughs, Colds, Bronchitis, Asthma and Consumption.

WILLIAM MURRELL, M.D., F.R.C.P.,

Lecturer on Pharmacology and Therapeutics at the Westminster Hospital; Examiner in Materic Medica to the Royal College of Physicians of London; Fellow of the Medico-Chirurgical College of Philadelphia,

Says:—"I have used with success 'Goudron de Blount.' The results have been good, and the preparation is popular with patients."

PREPARED EXCLUSIVELY FOR PHYSICIANS' PRESCRIPTIONS BY

R. E. BLOUNT, 33 RUE ST. ROCH, PARIS.

WHOLESALE AGENTS FOR UNITED STATES AND CANADA,

BATTLE & CO.,

CHEMISTS' CORPORATION,

Clinical Notes sent on Application. ST. LOUIS, MO.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

Clinical Lecture.

UTERINE HEMORRHAGE.—CORRECT TREATMENT OF FIBROIDS.—ENLARGEMENT OF THE ABDOMEN.[1]

BY E. E. MONTGOMERY, M. D.,
PROFESSOR OF GYNECOLOGY, MEDICO-CHIRURGICAL COLLEGE.

Uterine Hemorrhage.

Gentlemen: This colored woman, forty-four years old, presents the following history. Her mother died of dropsy, lasting a year before her death. The mother had several children, two of them girls, one of whom had a uterine fibroid removed some time ago, the other, the patient under consideration, has always been healthy. She had two brothers who died of phthisis. Our patient menstruated for the first time at the age of fifteen; the flow was always profuse but painless. She was married at twenty-two, and had a child a year later. The labor was long, lasting thirty-six hours, requiring for its termination the use of forceps. It was two years before she menstruated again. Four years later she had a second labor, again requiring the use of the forceps. She has never had an abortion. Three months ago, at her monthly period, she experienced intense shooting pains, accompanied with marked bearing-down sensations. This lasted several days, and was followed by a leucorrhœal discharge, which persisted until the menses made their reappearance, when she suffered from the same pains. Last month severe flooding from the vagina accompanied these sensations. She has been constipated for a month. She is not emaciated, although her appetite is poor, and her flesh is not especially abundant. Her heart and lungs are normal.

[1] Delivered at the Philadelphia Hospital.

There are certain conditions which will produce the symptoms from which this woman is suffering, but it is best not to arrive at a hasty conclusion.

Although everything at present points to pelvic trouble, do not at once exclude careful study of every organ, however remote. Is the trouble due to local or to constitutional causes? If you should happen to find some local cause which, in your mind, is sufficient to produce the condition present, do not let that fact deter you from studying all other possible sources.

Before commencing treatment, investigate all the sources of hemorrhage from the uterus, or, more broadly, from the vaginal tract. Disease of the uterine mucous membrane is frequently an important factor in these hemorrhages. Long-continued inflammation of this membrane sets up a granular endometritis, even producing polyps, which, in turn, may produce hemorrhage. The flow may be at the monthly periods, being called menorrhagia; or independent of these times, forming metrorrhagia—or simply hemorrhage from the uterus. Again, the walls of the uterus may produce a condition which gives rise to hemorrhage. Growths, which may be fibroid, appear, distend the mucous membrane, and, being supplied with numerous blood-vessels, rupture easily, producing the above phenomena. Malignant disease, involving the cervix or body of the uterus, is frequently a cause of hemorrhage. Degenerative changes following labor or abortion may cause hemorrhage. Imperfect removal of the placenta favors the growth of polypi, which in their turn favor the production of hemorrhage. Disease in the kidneys, liver or heart, the exanthemata, and typhoid or malarial poisoning, have produced occasionally, in their course, bleeding from the uterus. When there is an absence of heart, kidney, or liver trouble, when there is no poison in the blood, no fibroid, no malignant disease, not even inflamma-

tion of the mucous membrane lining the uterus—still there may be disease in the pelvis which is producing the flow of blood. Cellular infiltration of the pelvis, exudations into the tissue of the adjacent parts from extension through the Fallopian tubes, may cause the trouble. The circulation in the uterus is interfered with, and a hemorrhage, passive in character, makes its appearance. Disease of the ovary, especially cystic degeneration, is particularly prone to produce this symptom. In the absence of other apparent causes, it is well to remember this point. The influence of the ovaries upon the circulation of the blood in the uterus is most marked. When this cause is operating, local applications to the uterus will be made in vain. Bleeding from the vagina itself may be the real cause of the trouble, being mistaken for that from sources higher up. A vaginitis may produce this symptom; especially granular papillæ, which are common at the vestibule, may tinge the discharge blood-color.

Women rapidly lose confidence in the doctor who is unable to stop any such hemorrhage. So it is well to study all these cases with the utmost care. With this outline let us take up our present patient. This woman has severe tearing pains, bearing down in character. It is possible that this is due to pregnancy. The presence of menstruation does not preclude this possibility. I saw a case, within a few weeks, which illustrates this. I examined in consultation with another physician, a year ago, a woman who had enlargement of the uterus. This enlargement was fibroid in character, and I decided that it was areolar hyperplasia. With this condition, the woman had increased menstruation. I saw her again a month ago. The uterus was then enlarged, not symmetrically, and it was hard and firm at one point, localization of the fibroid growth having taken place. The hemorrhage had increased in quantity. There was no arrest of menstruation, on the contrary the flow was in excess. Two weeks ago, her physician writes me, she discharged a small fetus. The retained placenta formed the so-called fibrous polypus, to which there was enough blood supplied to prevent decomposition with its unpleasant results. There was no fibroid present; there was distinct thickening of the uterine walls, but no tumor.

Again, in some women, menstruation is increased for the first few months of pregnancy. In this woman, it may be due to a fibroid. If the pedicle is long, it may drop down into the internal os, becoming a valve, causing severe labor-like pains to produce the expulsion of the blood.

Fibroids of the Uterus.

With this introduction, let us return to our patient. She is, as I have said, forty-four years old, colored. There is a marked tendency in the colored race to fibroid enlargements, and less tendency to carcinoma or epithelioma. With the woman on her back, her limbs drawn up to relax her abdominal muscles, I introduce two fingers into the vagina. The cervix is large, hard and fixed, and projects into the anterior portion of the vagina. The uterus is immovable. In the posterior fornix there is a firm, irregular, dense mass which extends into the pelvis. This seems like a fibroid growth; still, we must not decide too quickly. With two fingers in the vagina and the other hand over the abdomen, it is possible with lax abdominal walls to outline the mass thoroughly. Here we find the abdomen hard and tense. In such cases, insist on the use of an anæsthetic. Do not commit yourself without careful search. Bromide of ethyl acts quickly, requires a small amount and is less likely to cause sickness than ether, and its effects pass off speedily, making it the best anæsthetic for office use.

Fibroids in the uterus begin as the result of irritation; there is a simple increase in the nutritive activity in the muscular layer of the uterus. The constituent elements of the normal tissue increase in size, pushing aside as they grow the adjacent tissue. Beginning in the uterine wall, as either a single or a multiple growth, as it develops it remains within the walls or intrudes into the cavity of the uterus, or extrudes towards the peritoneum; its direction varying according to its original position, as it grows in the direction of least resistance. These three varieties are called respectively, sub-mucous or polypoid; interstitial or in the wall; and sub-peritoneal or beneath the peritoneum. The fundus is well forward, the body of the uterus is small, and the mass is posterior, growing either from the back wall of the uterus or as the result of inflammatory exudation at this point. The uterus is more fixed on the right side. This is undoubtedly a fibroid enlargement, extending into the broad ligament. We should pass our finger into the cavity of the uterus to further

determine the diagnosis. This I will not take time to do now.

What treatment shall we pursue? This depends somewhat on the variety of the fibroid. First, the medical treatment would consist, naturally, in decreasing the flow of blood to the uterus. For this purpose strychnia, quinine, ergot, antipyrin, etc., may be tried. Ergot, by its action on the muscular coats of the blood-vessels and its contractile action on the entire uterus, may be of service. But it may drive a fibroid beneath the peritoneum, making it sub-peritoneal. On the other hand, it may force it into the cavity of the uterus and in this way expel it. Again, the circulation may be so cut off by the medication that the tumor may be in danger of sloughing, setting up septic trouble. Treating the mucous membrane locally may be of service. Changing the surface of the uterus cavity, by curetting or cutting partially through the vessels of the region, may cause these to contract, arresting the tendency to bleed. Dilatation or cutting of the cervix may be followed by extrusion of the tumor. Electricity has been a much vaunted agent in these cases; the positive pole being placed in the uterine cavity, the negative on the abdomen. With high currents cicatricial tissue is produced, which in its turn contracts. Cases have undoubtedly been benefited by this treatment, but the results are slight and transient, and the tumor steadily increases unless electricity is constantly applied.

Beside these measures, a radical course can be pursued. If the tumor is in the cavity of the uterus, twisting or cutting it with scissors or the wire *écraseur* will be of service. If the tumor is in the wall of the uterus, and the cervix is undilated, this is not easily accomplished. If the hemorrhages are severe, so that life or health are threatened, the removal of the ovaries may be considered. Menstruation does not always stop with the removal of the ovaries. In the case of this woman's sister, whose ovaries were removed, discharges have not ceased at all. I believe that this result is largely avoided by including the round ligament in the ligation of the pedicle. This increases the pressure on the ovarian nerve, which governs the blood supply of the uterus, and thus tends to reduce hemorrhage. These fibroids cease to grow at the menopause; they even decrease from this time on; but the menopause is generally delayed by their presence. A woman may die from hemorrhage before this period is reached. This woman is forty-four, she is near the normal time for the disappearance of her catamenia; but this disappearance cannot be regarded as a certainty for some years.

Enlargement of the Abdomen.

The next woman presents an obstinate case of vomiting and constipation, for the relief of which many remedies have been tried. The injection of oil high up into the alimentary canal has at last succeeded in bringing away a large amount of hardened feces. Her abdomen is distended, not quite symmetrically, more to the left than to the right. She may have a fibroid, an ovarian cyst, ascites, or be pregnant. In pregnancy there is usually an arrest of menstruation, and the subjective nervous symptoms so well known. The white lines on the abdomen here seen are not diagnostic of this condition. They are present in ascites, obesity, cystic tumor, or any condition by which the middle layer of the skin is stretched. The first step is to inspect the part. Is the swelling regular in shape? In pregnancy it is generally spheroidal with its main axis in the middle line, or rather, generally a little to the right side. In fibroid tumors the abdomen may be symmetrical or a little one-sided. Irregular projections are common. In cysts and ascites there is fluctuation as a rule. In a single cyst this fluctuation is marked; if the cyst be multolocular, it is less noticeable. On palpation a distinctive sensation is experienced. The fibroid presents a hard, dense, resisting mass, firm and irregular in outline. In the pregnant uterus of this size, although not by any means at term, irregular, rhythmical contractions may be felt, which do not easily mislead. Contractions in the abdominal walls do not imitate this rhythmical contraction. The fetal heart sounds can also be heard at this period in pregnancy. Both these signs are present in this woman. That the mass lies to the right side rather than to the left indicates that this is not this woman's first child. The uterus is large and there is a large amount of liquor amnii present, which allows the fetus to float.

—Sulphuric acid often contains traces of nitrous compounds which seriously interfere in the examination of waters. This fact is not as well known as it should be.

COMMUNICATIONS.

SALOL.

BY ALFRED EICHLER, M. D.,
SAN FRANCISCO, CAL.

Salol is one of the recent additions to our materia medica, but its merits are now almost universally admitted. It was discovered and first used by Swiss scientists, in 1886, and since then its use has spread all over the world. It is a white, crystalline powder, obtained by the action of carbolic acid on salicylic acid, therefore being, in chemical nomenclature, a salicylate of phenol. In composition, five grains of salol are equal to about two grains of carbolic acid and three grains of salicylic acid. Therapeutically, its effects are entirely different from those of either agent administered alone, depending on the fact that its constituents are united by chemical union, and represent, therefore, a different body. Salol possesses an odor similar to oil of wintergreen. It tastes like carbolic acid; it is soluble in water only in a very small measure, therefore watery solutions are impracticable. In alcohol, ether and oils, salol is very soluble. Further, it is interesting to know that this substance, although crystalline, cannot be reduced to a very fine powder, because the crystals have a tendency to adhere. The odor of salol may be noticed, after its administration, in the excretions as well as in the expired air. The dose differs, according to circumstances, from 15 to 120 grains a day. It should be remarked, however, that a case has been reported in which a half drachm of salol, administered to a previously healthy person, and distributed in five-grain doses over the day, has produced a severe rash over the whole body, which disappeared spontaneously in five or six days (*Medical Record*, March 3, 1888). A case of poisoning has also been reported, in which a young man had swallowed at once two drachms of salol. The resulting coma was followed by death. At the autopsy, degenerative changes were noted in the kidneys, as might be expected; the harm done was attributed to the carbolic acid contained in salol (*Medical Record*, October 11, 1890.)

As regards the method of administration of salol, it is best dispensed in pills, compressed tablets, capsules or emulsion. For external use lanoline, or a mixture of equal parts of lanoline and olive oil, offers a very good menstruum; if used externally in ointment form, it is usually prescribed in the strength of one part in ten of the ointment base.

Salol may be looked upon as a very efficient antiseptic, antipyretic and anti-rheumatic. When ingested, it is insoluble in the acid gastric juice, but it is dissolved in the alkaline intestinal secretion, being perhaps split up by the alkaline elements of the bile into its original constituents, which are then absorbed and taken into the circulation, the carbolic acid being rendered non-poisonous by the change into a phenate (carbolate) of soda. This assumption is corroborated by the fact that salol is readily decomposed by weak alkalies like bi-carbonate of soda—a point which should be remembered in prescribing. After absorption and diffusion through the system, the original constituents may be detected in the urine, the carbolic acid imparting the characteristic green color of phenoluria. As salol passes the stomach unchanged, experiments can be made with it in determining the activity of the stomach in propelling food. This test has been taken advantage of in dilatation of the stomach, and is available in all diseases where the motor power of the stomach is thought to be impaired. Of course, physiological tests of this kind depend so much on varying circumstances that definite conclusions can be arrived at only when a sufficient series of control experiments with healthy individuals is also carried out.

The antiseptic effects of salol are easily enough understood on considering that it is composed of two of the most powerful antiseptics now in our possession. As an antipyretic, it acts on account of being a derivative of salicylic acid, which itself has great heat-reducing virtues. Salol, however, is more easily tolerated by the stomach than salicylic acid, as it is insoluble and non-irritant; while the latter is a strong irritant of mucous membranes, and, therefore, cannot be tolerated by the stomach for any length of time in doses sufficiently large to produce good effects. That the salicylic acid is the antipyretic factor of salol is readily proved by the clinical fact that salol acts as an antipyretic only in large doses, twenty to thirty grains, containing from twelve to eighteen grains of salicylic acid. Small doses of salol reduce heat only in a very small meas-

ure. The carbolic acid and salicylic acid, into which salol is separated in the intestine, are eliminated mostly through the kidneys, as carbolate of soda and unchanged salicylic acid. Thus the urine is made antiseptic—a fact which has been taken advantage of in genito-urinary surgery.

The therapeutic action of salol resembles, to some extent, that of salicylate of soda. In comparing the action of the two remedies, much similarity may be observed, with some points in favor of salol. They are both excellent anti-rheumatics, salol, however, acting best in subacute rheumatism, especially when a short course of salicylate of soda has preceded its use. It will lessen the fever quickly, cause the pain to disappear, and the swelling will be reduced. As already mentioned, it acts better in chronic cases than in acute. For this purpose, it should be given in doses of not less than fifteen grains every three hours, preferably in wafer or capsule. Salol is especially efficient in those forms of rheumatism called lumbago. Sciatica, that uncertain disease, a veritable touchstone for medical skill, composed so often of neuralgic, rheumatic and malarious elements, often yields to large doses of salol.

In diseases of the alimentary canal, salol is also very efficient. It acts in the stomach merely as a mechanical antiseptic, similar to subnitrate of bismuth. In the intestine it becomes a full and strong antiseptic. This has been made use of to treat various diseases of the intestine, like dysentery and diarrhœa. It is advisable here to combine salol with other suitable agents. For chronic diarrhœas, in which a cleansing of the intestinal tract may be desirable, it is good practice to order fifteen grains of salol in an ounce of castor oil, to be given at a dose; or, when pleasanter medication is desired, one may prescribe:

℞ Salol . . . . . ℈ii
Ol. ricini . . . . . f℥iss
Syr. rhei . . . . . f℥ss
Pulv. acaciæ . . . . . ℥ss
Aquæ cinnamomii . . . . . q.s. ad f℥iv

M. Fiat emulsio. Sig. A tablespoonful every hour, until the bowels move very freely.

In typhoid fever salol has been used, but with no more success than other remedies. A disease running a regular course like typhoid fever will not mend its ways, or be aborted, under any one mode of treatment. Salol, however, has proved quite efficient to moderate the diarrhœa, and in conjunction with other therapeutic means, like cold ablutions and wet packs, with free stimulation and proper nourishment, it becomes a valuable adjunct in treatment.

Diarrhœa infantum offers a good field for the administration of salol. It is especially useful when the intestinal canal has been severely irritated by the products of faulty digestion. It may be ordered then in small doses, alternating with antacid remedies, like chalk mixture and bismuth.

Affections of the genito-urinary organs are often improved by the exhibition of salol. The most common of all, gonorrhœa, is much more tractable to treatment with salol than without it. The main good is rendered by making the urine antiseptic and unirritating by its administration. It acts thus considerably better than injections of antiseptic substances, being practically an injection from within outward. In treating a case of gonorrhœa with salol, it can be given in conjunction with the balsam of copaiba, usually prescribed. It may be ordered as in the following formula.

℞ Saloli . . . . . ℥vi
Bals. copaibæ . . . . . f℥iss
Syr. simpl.
Mucilaginis acaciæ . . . . . aā f℥iij
Tinct. lavandul. co. . . . . q.s. ad f℥viij

M. Sig. A tablespoonful three times a day, one hour after meals.

Large doses will prove more efficient for this purpose than small ones. The good effects are produced entirely by the action of the antiseptic and bland urine upon the inflamed urethra. Weak antiseptic injections into the urethra from without can also be used at the same time, and will assist in securing a speedy cure. It has been shown that salol, thus used, will shorten the course of the disease materially. Chronic cases improve under judicious use of this agent, if it be used with sufficient persistence. The urine appears, after the ingestion of these large doses of salol, in a much darker color, ranging from olive green to a blackish tint; this is caused by the carbolic acid contained in the urine, and need not be feared. Painful micturition is alleviated early, and the discharge is lessened promptly; in short, the acute inflammatory stage subsides much more quickly with, than without, salol.

In other diseases of the genito-urinary organs salol also deserves a careful trial. In operating for stricture of the urethra, it is advisable to have the patient take it one or two days before the operation, to render the

whole urethra aseptic. Perhaps the infiltration of tissues, so feared after operations in this region, might be rendered innocuous, if salol were given beforehand.

In diseases of the bladder it also proves useful. In cystitis it leads quickly to amelioration of the symptoms, and thus proves valuable in this troublesome and painful complaint.

Salol is of great value in treating different affections of the air passages. As the characteristic odor of salol may be noticed in the expired air, it is quite right to assume that it exerts a local influence besides the constitutional impression. It is of great value in the treatment of acute catarrhal conditions, for the treatment of which it may be combined with various other suitable agents. Terpin hydrate, for instance, acts well thus combined. The two substances can be dispensed in small doses in capsules, and given alternately every two or three hours. If salol alone is given, it will often be found to be acting like a charm. It soothes irritation, stimulates free secretion, and permits the patient to expectorate freely. Patients often remark when salol is given, that the medicine raises the phlegm quickly. It is also recommended in tonsillitis, as it will shorten the duration, besides lessening the fever, quieting the attending pain and relieving painful deglutition. In this affection an emulsion would seem to be the best mode of prescribing the drug.

During the recent invasion of influenza, salol proved of great benefit to the many afflicted. It was quite often prescribed, especially in that form of the disease simulating anginas and catarrhal sore throat. Alleviation of the rheumatic symptoms also quickly followed its use. In the treatment of other infectious diseases, salol has been found useful.

As already mentioned, in typhoid fever salol will assist in procuring asepsis of the intestines. In scarlet fever, it has also been prescribed, and it is believed continued administration of this drug will aid in shortening the duration of the disease, by eliminating the infectious material, besides reducing the temperature.

Externally applied, salol gives excellent results in some diseases of the skin. For a simple erythema, it may be used rubbed up with starch to a dusting powder. The powder form, however, is not very eligible, as salol has a tendency to ball together and form lumps. It is more suited to a paste. As it is white in color, it may be freely applied about the face. In sycosis of the bearded portion, if it is thus applied, it will cause good results. A good formula is as follows:

℞ Saloli . . . . . ʒij
Zinci oxidi
Pulv. amyli . . . . . āā ʒiv
Lanoline . . . . . ʒi

Of course salol may be added to this in any strength, providing the fatty vehicle is also increased. It is entirely innocuous when thus applied, probably not being absorbed through unbroken surfaces, and acting only as an antiseptic protective. The latter quality makes it also an admirable application in burns and scalds. It is then best used by dissolving it in some fatty oil, preferably olive oil, afterwards pouring it liberally over the injured surface, which is to be covered with soft lint.

A summary of all these properties will show salol to be a very useful addition to our materia medica. It is to be regretted that it is, like most other late additions, a proprietary article, imported from Europe and one which our laws prevent us from preparing ourselves; as a consequence it costs more than it would if it could be manufactured here.

SEXUAL PERVERSION AS A PHASE OF EVOLUTION.[1]

BY J. G. KIERNAN, M. D.,
CHICAGO, ILL.

The hypotheses advanced as to the origin of the sexual passion have been multiform. One just now gaining the ascendency was advanced by Clevenger a little more than a decade ago in the following language: "Dollinger and Drysdale have described fission of the monad preceded by the absorption of one form by another. One monad would fix on the sarcode of another, and the substance of the lesser or under one would pass into the upper one. In about two hours the merest trace of the lower one was left, and in four hours fission and multiplication of the larger monad began." Leidy insists that the amœba is a cannibal, whereupon Michets expresses

[1] Abstract of a paper read at the March meeting of the Chicago Academy of Medicine.

the opinion that each cannibalistic act is a copulative (if the term be admissible) one. Henry Lawson agrees with Michets.

Among the numerous hypotheses as to the origin of the sexual appetite none has referred its derivation to hunger. At first glance such a suggestion seems ludicrous enough, but a little consideration will show that in thus fusing two desires, the meaning and derivation of the primary one—desire for food—is not explained. The cannibalistic amœba may, as Dollinger's monad certainly does, impregnate itself by eating one of its own kind. Innumerable instances occur among algæ and protozoa, of this sexual fusion, appearing very much like ingestion. Crabs confuse the two desires by actually eating portions of each other while copulating. The female *mantis religiosa* eats the head off the male during conjugation. Some female spiders find it necessary to finish the marital repast by devouring the male, who tries to scamper away from his fate. The bitings and even the embrace of the higher animals appear to have reference to this derivation. Association often transfers an instinct in an apparently outrageous manner. With quadrupeds olfaction is most related to sexual desire and its reflexes; but not so in man. Ferrier diligently searches the region of the temporal lobe near its connection with the olfactory nerve for the seat of sensuality; but with the diminished importance of the smelling sense in man, the faculty of sight has grown to vicariate olfaction; certainly the lust of the eyes is greater than that of other special sense organs among bimana.

In all animal life multiplication proceeds from growth, and until a certain stage of growth, puberty, is reached, reproduction does not occur. The complementary nature of growth and reproduction is observable in the large size obtained by some animals after castration. Could the division of an amœba be stopped, a comparable increase in size would be effected. The seeming grotesqueness of these views is chiefly due to their novelty. While a primeval origin for both ingestive and sexual desire seems to have existed, and each seems a true hunger, the one being repressible, and in higher animal life subjected to more control than the other, the question then presents itself: What is hunger? But the reflection serves to show its potency in determining the destiny of nations and individuals, and what a stimulus it is in animated life. Most probably it originated in atomic affinities of inanimate nature.

Later biologists have adopted this theory. Rolph evidently regards the process of fecundation as one of mutual digestion, for he says: "Conjugation occurs when nutrition is diminished, whether this be due to want of light, or the lower temperature of autumn or winter, or to a reduction of the organism to minimal size. It is a necessity for satisfaction of a gnawing hunger which draws the animal to engulf its neighbor—to isophagy. The process of conjugation is only a special form of nutrition which results in a reduction of the nutritive income or an increase of the nutritive needs in consequence of the above-mentioned condition. It is an isophagy which occurs in place of an heterophagy. The less nutritive and therefore smaller, hungrier and more mobile organism, we call the male; the more nutritive, and, as a rule, relatively more quiescent organism, the female. Hence it is that the small starving male seeks out the larger well-nourished female for purposes of conjugation, to which the latter, the larger and better nourished is, in its motive, less inclined.

Westphal has reported an interesting case of perverted sexual instinct in a thirty-five-year-old woman, whose father had committed suicide, and who had been a housekeeper in a boarding-school for girls. She learned with difficulty in school. She had a cleft palate. As a child she had been fond of boy's games and male attire. From her eighth year on she had felt drawn to certain girls. She liked to express her love for them, kissed them and induced them to let her touch their genitals, which from her eighteenth to her twenty-fifth year she had frequent chances to do. When such chances did not occur she masturbated, particularly just before and just after menstruation, picturing to herself the loved girl. She had tried to abandon this habit, but when she attempted to control herself, she experienced a disagreeable odor and taste coming upward from her genital organs. This perverse tendency was exceedingly obnoxious to her and she desired to be freed from it. In her voluptuous dreams she appeared to herself to be a man. Physically there was no variation from the feminine type. The patient had latterly been depressed and apathetic; then unsociable and violent, using obscene language. These attacks were of regular occurrence. Before she came under Westphal's

observation, she had been exceedingly depressed, and confessed to her sister her love for a girl. As she finally manifested violence, she was sent to Westphal. Men were repugnant to her. During two months residence in the hospital she manifested no delusions or hallucinations, but weakness of judgment was evident. She contracted an affection for a weak-minded patient in the hospital. Five years after, the patient had no more relations with girls. She still masturbated, exciting her imagination as before by picturing female forms. She had attacks of excitement just before menstruation, and periods of depression just after; in these last she suffered from imperative conceptions, which are far from infrequent in these cases. Olfactory hallucinations frequently co-exist with sexual manifestation; hence their appearance in this case. That they are really an atavism will appear obvious when the relation between sexual excitement and olfaction in the lower animals is remembered.

In another case the mother had a neurotic ancestry, but was brought up in refinement. She fell in love with a farmer, and married him against her parents' wishes. The match proved unfortunate. He was prudent, and did not give his wife the comforts of life to which she had been accustomed. She finally become demonstrably insane, deserted her home, and was found one morning behind a pile of wood clasping to her bosom a newborn babe. The child was taken care of by friends until the mother died, and grew up a beautiful girl, but when about seventeen years old exhibited an errabund tendency. She displayed a great liking for boyish games and attire, but a repugnance to suitors. She was persuaded into a marriage with a man to whom she became so repugnant that he deserted her, whereupon she sought refuge in a Pennsylvania almshouse, where she met the second case who came under Dr. Wise's immediate observation. This last woman had an insane ancestry on the maternal side; she preferred muscular sports and labor; she was averse to attention from young men, and preferred the society of her own sex. She was forced into a marriage with a man to whom she bore a female child, but who deserted her, relations with her husband being distasteful. On being abandoned by her husband she went West, assumed masculine attire, became a hunter, and spent several years among the Indians. On her return she published a very quaint description of her hunting life. Becoming reduced in circumstances she sought refuge in the almshouse with the first patient, who became strongly attached to her and the attachment proving mutual, the two took up their abode in the woods as husband and wife. The second patient assumed the name of "Joe," and provided for the two by hunting and trapping. In 1876, the two returned, the wife introducing her "husband" to her uncle. She was kindly received, and her "husband" was hired to work about the place. One day "Joe" was found to be a woman in disguise, whereupon the uncle was so indignant that he caused "Joe's" arrest. She was imprisoned for four months, during which time the "wife" visited her and carried delicacies to her. At length the neighbors prevailed upon the uncle to have the young woman released. When she came out of prison she lived with her "wife" again. At that time the estate of the "wife's" mother was settled, and real estate valued at several thousand dollars became hers. This property she has not claimed, but still leads her old curious life. Her husband died in the Willard Hospital for the Insane. She is about forty-six years old, while her husband was a few years her senior. The husband was admitted to the Willard Hospital for the Insane in consequence of maniacal attacks. After admission "Joe" tried to have sexual intercourse with her associate. "Joe" said that with her husband she had never had anything but repugnant sexual relations, but with her "wife" sexual satisfaction was complete. She had an enlarged clitoris, covered with a large relaxed prepuce. She had periodical attacks of sexual furor.

Blumer reports a case in which psychological phenomena closely resembling those of hysterics were manifest. The patient, a male, loved a man in the purest manner possible. To gain the affection of the loved object he wrote poetry rather above the average of that poured out by enamored youths. His poetry was so pervaded by the dreamy sentimentality of the Platonic philosophic views of the relations of the sex as naturally to create a suspicion that this philosophy might have the same origin. The pervert used endearing names and wrote pseudonymous letters to his "beloved," scurrilously attacking himself as a means of drawing attention to his affection.

Sodomy sometimes results from an imperative conception, or from this arising from a vice or from both conjoined with congen-

ital defect. This last was the case with the amours of the suicide paranoiac Ludwig, of Bavaria, and Wagner, of "Tannhäuser" fame. The letters of the great composer to the King demonstrate this.

One such case came under my own observation. An insane Bohemian girl was admitted to the Cook County Insane Hospital without a history. She had a virginal vagina and hymen, and a funnel-shaped anus. Subsequently her lover came under my care. He admitted she was very lascivious, but feared pregnancy, and had permitted coitus only by the rectum. As a result both became incapable of coitus except when performed in this manner. The erethism of the girl finally resulted in an attack of mania-like sexual furor, from which she died. This flung her lover into a depression from which he recovered under treatment, and he finally made a happy marriage.

Sexual perversion may furthermore reappear in certain races under the influence of old tribal customs. Pæderasty, according to the oath of Hippocrates, was no more of a crime in Greece than ordinary lasciviousness. The boy loves of the Greeks were common features. Socrates and Plato indulged in this love. Pæderasty, as with the Pueblo Indians, often had a religious phase. Campbell points out that both prostitutes and sodomites were religious attachments even to the Hebrew temples. There were consecrated prostitutes and consecrated sodomites whose receipts formed part of the temple income, while the hire of the promiscuous prostitutes and promiscuous sodomites could not be accepted by the temple. The influence of such customs was shown in the relative frequency of pæderasty in France (Marseilles) and Italy (Calabria) where colonies had been early established by the Greeks. In tribes where pæderastic ceremonies were part of the religious exercises, there would be no popular aversion to pæderasty. Indeed, Schopenhauer views pæderastic performances by old men as an illustration of the beneficence of nature in preventing the propagation of the defective beings.

All of these manifestations may appear as phenomena of periodical insanity, as substitutes for epileptic attacks, in paretic dementia, at the onset of puberty and senility in man, and of puberty, pregnancy, senility and the menopause in woman. Furthermore, they are frequently produced on the neurotic soil of the male and female masturbator. The female masturbator of this type usually becomes excessively prudish, despises and hates the opposite sex, and frequently forms a furious attachment for another woman, to whom she unselfishly devotes herself. The same phenomena may be observed in male masturbators. These latter, however, reach insane hospitals early, as their gaucheries are demonstrable.

The female masturbator has not escaped the keen eye of Balzac, who depicted her in his *Demoiselle avec les Teux d' Or.* Browordel has reported an excellent case of the periodical insanity type. The unstable emotional balance of the periods of evolution and involution, like puberty, pregnancy, the climacteric and senility, explains the sexual perversions of these periods.

That these abnormal sexual phenomena may originate in imperative conceptions is readily demonstrable. A woman in the sexo-emotional condition produced by pregnancy manifests aberrant "longings." Pregnant women have insisted on sexual intercourse with a husband and have then killed and eaten him. Recently delivered dogs and tigers often devour their offspring. In the male, similar phenomena occur at the sexual orgasm, when great emotional exaltation exists and the will is in abeyance in consequence. A man may be then seized by an imperative conception differing in character from the voluptuous. Seeing a woman's shoe he is unable thereafter to experience sexual emotions without this conception. Ridiculous as this may seem, more than one victim of this imperative conception has been tried for theft therefrom resulting.

Lawson has reported such an adjudicated case. Sprague, the accused, was arrested immediately after having assaulted a young lady by throwing her down violently, removing one of her shoes and running away with it. He made no attempt to steal anything else, although she had on valuable jewelry. When the trial came on, insanity was alleged as a defense. Numerous witnesses, the principal of whom was the father of the defendant, a clergyman of the highest respectability, testified to the erratic conduct of the prisoner. A family history was elicited which bore most pertinently upon Sprague's case, his grandfather, grandmother, great-grand-uncle, three great aunts and a cousin having been insane. He had himself in his youth received numerous blows and falls upon the head, and within a year from the last head injury he had devel-

oped severe headaches, associated with which his friends noticed a bulging of the eyes. About this time the prisoner developed a fondness for stealing and hiding the shoes of females about the house, and it was found necessary by his relatives and the female domestics to carefully conceal or lock up their shoes to prevent his abstracting them. Upon investigation it was discovered that the act of stealing or handling the shoes produced in him sexual gratification.

About a decade ago I pointed out that not a single abnormal sexual manifestation by itself, could be regarded as evidence of insanity leading to irresponsibility, hence I most heartily agree with Krafft-Ebing, Spitzka and Tarnowsky, that the mere existence of anthropophagy, necrophilism or sexual perversion, unaccompanied by other evidences of nervous and mental disease, is not sufficient proof of insanity.

Between the cannibalistic sexual intercourse, the expression of protoplasmic hunger in the amœba and the picture drawn by Finck and Maudsley looms a seemingly impassable gap, yet evolution has, as demonstrated by these perversionary atavisms, bridged this gap, and from and by what would *a priori* seem the utmost expression of egotism, has developed a secondary "ego" which inhibits explosive manifestations of egotism and hence is an efficient moral factor.

COMMON COLDS.

BY A. NOEL SMITH, M. D.,
DOVER, N. H.

When an individual has "taken cold," as is said, there is certainly a departure from a healthy or normal condition. Although most people have contracted a cold many times in the course of their lives, and had no structural disease as a consequence; yet it is to my mind not only erroneous but dangerous to entertain a belief, as many, more especially non-professional people, are apt to do, that a cold scarcely ever has sequels of a serious nature. And this error in belief has destroyed the lives of many.

No person, it is true, dies merely of a *cold*, as long as it is nothing but a cold simply; but when, from inattention and neglect, it results in certain diseases which at once suggest themselves to the mind, a cold may, and often does, indirectly prove fatal. "Colds destroy more than plagues," was the answer of a physician to one of his friends, who in reply to an inquiry as to his health, said, "I am very well, having nothing but a cold."

Another error into which many are apt to fall is, that colds require no treatment; and I have heard of individuals who not only considered colds as free from danger, but even thought, or pretended to think, them wholesome and promotive of good to the organism in some way which they could not explain. No doubt a man had better have a cold than a more grievous disease, but it must be infinitely better to have neither.

It is unnecessary to note the symptoms of a cold; all are only too familiar with them. Colds seem to be of no certain duration or continuance; and many have been the remedies employed to cut them short in their course. Large draughts of cold water; hot water; hot brandy; whiskey; hot lemonade; gin; eating heartily, or "feeding the cold;" fasting, or "starving" it—all have been tried with variable results.

Neglected colds may be, and are, responsible for many affections which afflict us. We meet every day in our practice some form of the many throat troubles, so common in this changeable climate, which are brought on by exposure to cold and moisture. Very few people are exempt from catarrhal affections of some portion of the respiratory tract. Perhaps acute bronchitis most frequently results from taking cold. Of course every case of such disease does not have this common origin; as bronchitis frequently occurs in connection with other diseases, and also arises from traumatic causes.

Not only may colds be responsible for a catarrhal process in the larger bronchial tubes, but the process may extend downwards, developing catarrhal pneumonia and caseous phthisis. Then, although croupous pneumonia depends upon a specific element for its etiology, and is therefore a self-limited disease, persons predisposed to this affection by constitutional vice may find exposure to cold acting as an exciting cause at any time.

So long as the results of a cold are manifest in the larger bronchial tubes only, perhaps there is not much to fear; but when the smaller tubes become involved, there is everything to fear; for continuous collapse of the air vesicles from obstructed bronchi must end in caseous phthisis.

Now seeing these things are so, and that the dangers to the human economy are so numerous from neglect of the so-called "common colds," what is the inference to be drawn? Evidently this: that we ought to strive in all possible ways to lessen these dangers by prophylaxis, living ourselves, and teaching others to live—especially in this changeable climate—in such a manner as to reduce the number of colds contracted from time to time to the lowest possible number. This can be accomplished only by giving close attention to all hygienic rules. In the first place, a person must have good and abundant food, at regular intervals, in order to be well protected against the arrows of disease. The clothing must be such as will afford equal warmth to the surface of the body and the extremities. It must be comfortable and easy, and not interfere with sufficient perspiration over the surface of the body. The bad results from chilled extremities and cold feet can scarcely be over-estimated. The importance of proper clothing and the necessity of changing with the seasons are well illustrated in the lower animals. The horse changes his coat in the spring and autumn, and in the winter it might be said he has a double coat. The birds moult their feathers in the fall, and the new feathers thicken as winter comes on. The neck does not require so much protection as the body below this point; neither do the head and face. It is a mistake to muffle up the neck too much, especially when walking, as this part is richly supplied with blood-vessels. and does not chill easily.

Again, pure air is essential to the maintenance of health. I firmly believe that in order to enjoy the greatest immunity against colds, one must accustom himself to be out-of-doors in all weathers; and so long as he is protected so that he will not get wet feet, or get wet through, always remembering to keep the mouth closed, and to breathe through the nose wholly, there is no more danger of catching cold out-of-doors than in.

Another prophylactic measure consists in proper and continuous expansion of the lungs. As I have intimated above, certain forms of phthisis and pneumonia will result from the inflammatory condition established by collapse of the air cells of the lungs, on account of obstruction of the bronchial tubes. Now, this result may be avoided very frequently by keeping the lungs, especially at the apices, well inflated with pure air. I believe this process to be one of the most valuable in the prophylactic management of common colds; as I have known persons who, previous to systematic deep inhalations of air, were afflicted often with colds, and thereafter were seldom troubled. And not only is such a course valuable as a preventive, but an established cold may often be cleared up by persistent and frequent exercise of the respiratory muscles.

To conclude, as so many and grave diseases may and do have their origin in the common cold, and as guarding against and preventing disease is admitted to be far better and more philanthropic than to cure it when already established, let us endeavor to educate our communities in every prophylactic measure that experience of ourselves and others may suggest, and thus assist in the prevention of suffering, and in the prolongation of human lives.

PERISCOPE.

Sterility.

The *Archives of Gynæcology*, January, 1891, quotes Dr. Robert Bell, in the *Medical Press*, as saying that while it must be admitted that impotency in the male occasionally is present, it is of such rare occurrence that when it does occur it may be looked upon as phenomenal; moreover, it can generally be accredited to the effects of some previous gonorrhœal or syphilitic attack. That it may, however, occur idiopathically is also admitted, but the percentage of such cases is so very small that for all practical purposes they scarcely deserve consideration. In the female also sterility of an idiopathic origin may likewise be viewed as a very rare defect. In short, it may be accepted as a principle that sterility in either sex is the sequelum of some diseased as opposed to a defective condition of the sexual organs. I consider the one great factor in its production to be a diseased condition of the endometrium. This may be due to various causes, such as stenosis, catarrh, hydrostatic congestion due to a defective heart action, or some vascular derangement induced by obstinate constipation. It may, on the other hand, be aggravated by flexions, versions or prolapsus. Stenosis as well as retroflexion and anteflexion are credited with many evil consequences such as dysmenorrhœa, menorrhagia, etc., but these

various pathological conditions would never co-exist were the endometrium healthy. We are not sufficiently alive to the fact that endometritis proceeding to metritis is a pregnant cause not only of the various affections of the uterus, but of those of the tubes and ovaries also. Take stenosis of the cervical canal for example. In nine cases out of ten it is due to a hypertropic condition of the mucous membrane due to chronic hyperæmia. If such is the case it is needless for me to remark that forcible dilatation, which is so frequently resorted to, in the circumstances can be hardly anything more or less than injurious. If, on the other hand, stenosis is really the primary affection, it does not necessarily imply sterility or even dysmenorrhœa; that is, if the upper reaches of the endometrium are healthy; and for this reason that the spermatozoa can impel their way through as narrow a canal as a fluid can escape by, and blood, if not coagulated, can dribble through a channel of very minute caliber as quickly as it is thrown off in menstruation. If, however, it comes in contact with tissue, be it ever so slightly inflamed, its fluidity decreases and hence the distress which so frequently accompanies stenosis, because coagula have to be forced through the contracted channel by uterine action. Now, just as in endrometritis the caliber of the cervical canal becomes narrowed, so does that of the Fallopian tubes, and more especially does this occur at their outlet into the uterus where the lining membrane, in consequence of its hypertrophied condition, tends to occlude the orifice. In this way hydrosalpinx and pyosalpinx frequently originate. To my mind the one great factor of sterility is endometritis, and in this I include endocervicitis.

Not so very long ago it was accepted as an axiom, that if a woman had ever been the subject of inflammation of the womb she could never become pregnant. Now, however, it is beyond question that this hypothesis is false. Nay, more, I have known of women who have even been the victims of gonorrhœal endometritis to bear children after that was removed. This is a much further advance than pregnancy becoming possible after a simple endometritis had been cured. Endocervicitis may certainly *per se* be the cause of sterility, and doubtless occasionally is, but it is so rarely disassociated with a similar condition of the endometrium, and endometritis is never present without endocervicitis being co-existent. If we examine the discharge which is secreted so abundantly in endometritis, we will find that it frequently consists of a muco-purulent fluid of an acrid nature. The character of this fluid is so irritating that its passage over the vaginal portion of the cervix denudes it of its mucous surface, giving rise to erosion and pupillary ulceration, and not infrequently to vaginitis as well. The effects of its acridity, then, being so injurious to the mucous surfaces over which it passes, can it be doubted that it will have a destructive effect upon the spermatozoa when they come in contact with it? Though this were not the case, however, the disorganization produced by it on the endometrium would certainly deprive this membrane of the power of affording a proper nidus for the ovum, if even it were to become impregnated. If pregnancy does not follow marriage within a reasonable time, there must, as a rule, in the majority of cases, be present some faulty condition of the generative organs of the female.

Flexions are frequently accredited with being factors of sterility. This, however, is only because they indicate an unhealthy condition of the uterine lining membrane and walls. In short, they are only accessory conditions to, and dependent upon, the one prime factor of sterility, viz., endometritis. Now we know that not unfrequently unmarried women are the victims of this disease, and though in many instances it may not be sufficiently severe to interfere very much with the geueral health before marriage, the case is very much altered after that event, and this for obvious reasons. As time goes on the diseased condition of the uterus does not tend to diminish, but on the contrary to increase, in consequence of the periodical excitement the organ undergoes. The unhealthy condition, which at first was trifling, becomes in consequence more and more pronounced. It is little wonder, therefore, if sterility is persistent. If, however, the endometrium, by judicious treatment, is restored to its normal condition, I have no hesitation in affirming that it matters not how long after marriage this is accomplished, the most powerful as well as the most frequent barrier to conception will have been removed. As I have before stated, endocervicitis may exist for a time without the endometrium being also involved, but sooner or later, either by continuity of tissue or by the repeated monthly efforts of the uterine walls necessary to pro-

pel the menses through the narrow canal, or both combined, the endometrium must of necessity sooner or later become involved. The more extensive my experience becomes the firmer does my conviction grow that endometritis is the one great cause of sterility, and not only of sterility, but of flexions and oöphoritis also. This being the case the treatment of those affections is not difficult to conduct and bring to a happy determination. To carry this out successfully, however, it is needless to insist that during the process complete abstinence from marital intercourse be enjoined.

Varieties of Hydrocele.

Duplay, in an article in *l' Union Medicale*, translated in the *Medical News*, March 28, 1891, mentions a large variety of hydroceles which may be encountered in the inguino-scrotal region, together with the means of differentiating them. It is an easy matter to distinguish the so-called "hydrocele by infiltration" from hydrocele with effusion, since the former is simply an œdema, and is not accompanied with fluctuation and transparency, while the tissues retain the imprint of the fingers. More difficult is the diagnosis between encysted hydrocele of the testicle and epididymis and vaginal hydrocele. The differences here consist in the variable connections which exist between the sac and the testicle. The effusion in hydrocele of the tunica vaginalis entirely surrounds the testicle, and the latter occupies a postero-inferior position, aud is a little internal to the tumor. This is the rule, but it is well to remember that in cases of inversion of the epididymis the testicle is found in front of the effusion. In encysted hydrocele there is a cyst which takes its origin between the testicle and the epididymis, either on a level with the head of the latter or a little lower. This cyst increases in volume, little by little, until it conceals the testicle, but it always remains attached to the head of the epididymis by a point more or less constricted, as large as the thumb or two thumbs, and it is always possible to outline the gland, which is impossible when it is enveloped by an effusion.

It is necessary to distinguish several varieties of vaginal hydrocele, and to describe separately congenital hydrocele, and hydrocele in Dupuytren's pouch. In the fetus there is nothing in the tunica vaginalis, and it is at the time of the descent of the testicle that a prolongation of the peritoneum is dragged down, constituting the serous cavity. Congenital hydrocele is that in which the peritoneo-vaginal prolongation is not separated from the large abdominal cavity. The liquid which the sac holds is then very easily reducible, and returns into the abdomen very rapidly when the passage is large. If, on the contrary, the passage is small, it may require some time to return all of the fluid. Hydrocele in Dupuytren's pouch is a second variety of congenital hydrocele. It is easy to confound this variety with bilobar hydrocele. The latter is that in which, owing to the resistance of the fibrous tunic of the pouch, a bridle is formed which divides the sac into two portions. Hydrocele in the pouch is a variety in which the peritoneo-vaginal conduit, instead of becoming obliterated after the passage of the cord, is closed only in its upper portion, this closure completely shutting off communication with the peritoneal cavity. If, under these circumstances, an effusion occurs into the tunica vaginalis, it will divide into two portions, the one occupying the cavity which extends from the base of the sac to the orifice of the canal, and the other an intracanalicular dilatation. Occasionally the peritoneum is pushed back, and it then forms a subperitoneal sac, which may be felt in the iliac fossa. In some cases, vaginal hydrocele runs even to the external orifice of the vaginal canal.

Of hydrocele of the cord there are two varieties: in one, the cavity presents itself above the line of the cord, and evidently consists of the non-obliterated remains of the peritoneo-vaginal canal. It is seen as a small, resistant, transparent tumor, at a point more or less elevated above the passage-way of the cord. Some cysts of this kind at times descend to the lower portion of the pouch, and it is then possible to confuse them with ordinary hydrocele. On the other hand, the obliteration of the peritoneo-vaginal canal may take place in its lower portion, all the upper portion remaining patulous, and forming a serous cavity which may be taken for an hernia or an effusion. In this variety, which is very rare, the effusion descends along the inguinal canal, and forms a transparent, reducible tumor. This is, if we adopt the name given by Chassaignac, a peritoneo-funicular hydrocele.

Finally, there is hydrocele of the hernial sac, which may extend the length of the in-

guinal canal, and even reach to the base of the pouch. The hydrocele is a serous cavity filled with liquid; sometimes the intestine and omentum are absent, and there is no communication with the peritoneum, but at other times an organ is found in the sac which should be in the abdominal cavity. Hydrocele of the hernial sac does not descend to the base of the scrotum, and it is easy to recognize it. Nevertheless, the diagnosis between it and peritoneo-funicular hydrocele, or cysts of the cord, may be quite difficult.

Safety of Hypnotism as a Remedy.

So much has been written lately of the dangers of hypnotism that it is interesting to note a very interesting and remarkable article on the therapeutic use of hypnotism, by Dr. Hamilton Osgood, in the *Boston Medical and Surgical Journal*, March 26, 1891. In concluding, Dr. Osgood says: I wish again to allude to the feeling that hypnotism is dangerous. If it be applied with the necessary technical understanding and the proper suggestions, the causation of hallucinations being avoided, and if the patient be treated with the gentleness and consideration which is always shown a patient under any other circumstances, *I distinctly deny that danger attends the use of hypnotism.* I do not speak from hearsay, but from a moderately large experience. It is easy to see how harm could arise where a susceptible patient is used as a plaything for the creation of hallucinations, day in and day out, at the sweet will of medical students and of physicians indifferent to all else than their own amusement, indulgence of curiosity or a desire to watch effects. Charcot's patients are trained, *strained* one may say, to the highest degree and by startling and exhaustive methods. It is no wonder that he sees nervous disturbance among them, and that they became mere puppets. Charcot, therefore, declares that only hysterical subjects or persons of what he calls "a peculiar nervous make-up," can be hypnotized, and that hypnotism will create hysteria. This is curiously refuted by all the statistics published by men who hypnotize according to the Nancy methods, men whose united testimony refers to hundreds of patients to Charcot's one. This is my experience, and further, while the larger number of my patients have been non-hysterical, among them strong men, those who were hysterical, and have responded to the treatment, have become free from the nervous ailment.

Is there no argument in Bernheim's decided assertion, after more than nine years of large experience, that he never has seen one case in which harm of any sort has resulted? He shows how harm could be caused, but also that it is wholly unnecessary. I can show that harm has been caused by the use of baths; but does one stop bathing? Liébeault has used hypnotic suggestion during thirty years of large practice and *he* pronounces its proper application harmless. It is singular that mere prejudice strikes stronger roots in some minds than simple truth. The fact is, however, that the laity is more independent of the opinion of the physician than once was the case. People will decide for themselves, and the very results of hypnotic suggestion will be sufficient proof.

A well-known physician, who is a good hater of hypnotism, but who, of course, has not used it himself, else he would have another opinion, said to a relative of a patient whose case I have mentioned, that hypnotism was hurtful. "Yes," was replied, "but there is my cousin, who for twenty years was constantly intemperate and now cannot be made to touch liquor, and his health has greatly improved. This was the result of hypnotism. That is proof enough for me."

Can any fair-minded man fail to see the great value of the treatment in view of such results? One can merely quietly continue the use of a remedy which, in many senses, nothing can replace, and let prejudice take care of itself. No physician, who practically has followed the methods of the Nancy School, confining suggestions to the functions of the organism, will admit that he has ever seen a result in any sense injurious to the patient. Consider the vast number of patients which this statement includes!

One argument against the use of hypnotism I cannot leave unmentioned. It is, that in using it a physician, simply because this thing has in the past been largely in the hands of quacks, might injure his practice or hurt his standing. This needs only one word of reply: To put it mildly, it is the argument of a man without courage. Nevertheless, the timid physician, who *believes* in hypnotism, doubtless finds reason to be thankful for the fact that to-day hypnotic suggestion stands firmly upon scientific ground, and that it is practiced abroad by

men whose judgment is ripe and whose medical attainments occupy the first rank. Personally, I should feel that I were doing wrong, and were disobeying duty, if I were unwilling to apply hypnotic suggestion wherever I saw it were likely to aid the patient. And this is the outcome of my experience in this branch of therapeutics.

Treatment of Chorea.

The notable improvement in many cases of chorea during the administration of sedatives, such as chloral or bromide of potassium, has long been recognized by the profession. Dr. J. A. Jeffries has recently published, in the *Medical News*, his experience with sulphonal. Five of his cases were simple chorea—that is, first attacks of recent origin. These all recovered within three weeks. In two arsenic had failed, in two it was never used, in the fifth either arsenic or sulphonal alone failed, but together they were quickly followed by improvement. Sulphonal was also employed in five other cases, which were either of long standing or second or third attacks; four were at the period of puberty. Three of these cases got well, at least for a month; in three arsenic had failed; in two it was not used. Two did not recover with any treatment. All the cases were also ordered a daily sponge bath, simple diet and sleep in the middle of the day. Although the treatment has only been employed in ten cases, and two of these have shown no improvement, the results in the other cases appear sufficiently encouraging. In reports upon simple chorea, however, it is well to check the results by the average duration of such cases when not under medicinal treatment.

The attempt to place any drug or combination of drugs in the relationship of a specific to chorea represents a form of gross and inexcusable empiricism. Simple chorea, so-called, or better, Sydenham's chorea, is the only possible exception to the above statement. Certain choreas are of organic origin (post-hemiplegic), or at least are so classified at present. Such a form of chorea is but little affected by drugs which benefit the simple type. Huntington's chorea, or the hereditary form of the disease, is notoriously obstinate in its resistance to the curative effects of all drugs. There are forms of chorea which are distinctly of reflex origin. The celebrated case, reported by Hamilton, of chorea dependent upon an eczema of the arm, the choræic movements beginning with the development of the eczema, limited to the same arm and disappearing with the cure of the skin affection, is a striking example. Other reflex relations may exist in affections of the nasal mucous membrane, in defects of ocular muscle accommodation, in preputial irritation, or in a variety of other peripheral causes. Laryngeal chorea is almost invariably found to be associated with a local condition of disease in the larynx. Two other forms of chorea, one occurring in pregnant women and dangerous, the other in the aged, are recognized. Rational therapeusis demands, of course, the removal of the cause, and a reflex origin should always be eliminated. Often the symptom of nervous twitching will afford no clew to such a cause. In the simple or idiopathic, or Sydenham's chorea, the following plan of treatment is that observed with most success in the clinic for nervous diseases at the New York Polyclinic. The child is removed at once from school, put on a nutritious and non-stimulating diet, freed from all excitement or mental strain, and given a combination of iron, preferably the dialised, with Fowler's solution of arsenic, 20 minims of the former and 5 to 10 of the latter, three times daily. If there is evidence of malnutrition, as is usual, cod-liver oil and malt is added. If the case does not improve in one week, or two at most, it is put to bed and kept there for three weeks, other treatment being continued as above. In private practice, galvanism to the spine, using the continuous current and small doses at first (5 to 8 milliampères), with seances on alternate days, is at times a valuable adjunct to other methods. Very few cases will be found which are not markedly benefited, if not entirely cured, by the above plan. The arsenic may be increased, if necessary, though the possibility of arsenical poisoning should always be recognized.—*Archives of Gynæcology, Obstetrics and Pædiatrics*, February, 1891.

Keloid.

Dr. Bryson, in the *New York Medical Journal*, March 7, cites an article by Dr. A. F. Plicque, in the *Gazette des Hopitaux*, October 11, 1890, as saying that the anatomical and pathological nature of keloid is much in dispute. Alibert classifies it with cancerous dermatoses; Jacobson considers

it a particular variety of sarcoma; Tilbury Fox as a tubercular affection; and Hardy as a simple deformity of the skin. To account for it more satisfactorily, Bazin invokes the aid of a special diathesis—the fibro-plastic. Erasmus Wilson thinks it a trophic disturbance; Deneriaz, a microbic infection; while Kabler finds a certain relation between keloid and syringomyelia. It has also been suggested that keloid in general is the development on scrofulous soil of what would otherwise be sarcoma, and that it is an illustration of the antagonism of disease. Pathologically, there is no essential difference between the cicatricial form and the spontaneous variety. Embryonic cells penetrate deeply and congregate about the sheaths of vessels far beyond the definite limits of the disease itself. Hence the necessity of extensive ablation in view of total extirpation. True keloid is covered with the papillary layer of the skin, which the cicatricial variety is naturally without. There is also a slight and immaterial difference in the connective fibers of the two forms, but they both belong to the group of fibro-sarcomata. Just here lies an explanation of the benign nature of the disease. As it progresses, the embryonic cells take on the character of definite connective tissue which gradually obliterates the vessels of keloid that in themselves are few in number. Hence the slow devolopment and frequent arrest of sarcomatous elements, of which the essential cells and their nuclei become more and more infrequent and gradually disappear. One close relation to malignant growths, however, is the chronic tendency of keloid to return after removal or treatment.

Pain and discomfort are prominent symptoms. Anything that will relieve these is worthy of consideration. The agent now most in favor is scarification according to Vidal's method. The scarificator, a small, sharp bistoury, is held like a pen between the thumb and index finger. Incisions—perpendicular to the skin and not oblique—are made lightly and rapidly by movements of the fingers and not from the wrist. Quadrilateral incisions are best, extending slightly beyond the area of morbid tissue into the region of healthy skin. This procedure causes considerable pain, which diminishes with each sitting, owing to further division of nerve fibers. The slight hemorrhage may be arrested by pledgets of absorbent cotton applied with the left hand during the scarifying process. A Vigo plaster is then applied. Union is by first intention, all traces of the incisions disappearing in three or five days. While the operation is slight in itself, antiseptic precautions are absolutely necessary to avert all possible danger of consequent erysipelas. Scarification can be applied about once a week at first, and then more frequently if the surface is extensive. Pain is the first symptom to disappear under this treatment, two sittings having been sufficient to relieve it in a case of Vidal's, where it was so severe that the surface had to be protected from the clothing by a wire breastplate. Brocq recommends electrolysis by means of needles plunged into the tumor to the depth of six or seven millimeters. The current—five milliampères—is passed for thirty seconds. The whole surface is thus gone over, insertions of the needle being as near together as is possible without infringing upon the little white circle that appears upon its withdrawal. On account of inflammatory reaction, it is wise to give only weekly or fortnightly sittings. Perhaps the very best plan of treating keloid locally is to alternate scarifications and electrolysis. The diathetic condition, whatever it is, must receive attention. Quinine, where there has been a malarial element, and salicylate of sodium, in a lithæmic subject, have relieved the pain of keloid.

Morphine Habit Treated by Gradual Withdrawal.

Dr. Cottel, of Portland, Oregon, in the *American Practitioner*, states that he has obtained a positive cure in forty cases of morphine addiction by means of the following "mistura diabolica": Morphine sulphate, a variable amount; fluid extract of viburnum prunifolium, four drachms; elixir of ammonium valerianate, three ounces; elixir of sodium bromide, two ounces and a half. The dose is a teaspoonful as required. The amount of morphine is a diminishing one, beginning at a point somewhat below that which has been taken habitually. Tincture of opium may be substituted for the morphine with advantage in some cases, the size of the dose being proportionately increased. The bromide of sodium is in the proportion of five grains in each drachm of the excipient. The mixture can be readily given up after the morphine is dropped from it.

This plan of treatment involves the

gradual withdrawal of the narcotic in cases where there is a *bona fide* desire to be cured; immediate withdrawal is cruel and unscientific, and it is inapplicable where espionage and restraint are not within reach. Rapid withdrawal of the narcotic has the same objections, and the tendency to relapse is greater than when the gradual weaning has been resorted to. The writer adds: "I am confident that no case is incurable, however chronic, provided the general health is fair." The main point will be to win the confidence of the patient in the physician's power to cure, and to secure this he is to be taught that the substitute used by the physician contains no morphine. If he finds that the substitute contains morphine his co-operation will not be given, since nearly all opium fiends have had a sad and fruitless experience in regard to the tapering-off process. It is well not to hurry the reduction of the dose of morphine; in chronic cases, or those of persons who have been taking ten grains or less daily, the patients will usually not notice the abstraction of a grain each week, although some must be dealt with even more patiently than that. In smell and taste this mixture is truly diabolic, and many patients will say they can do without the horrible stuff long before the time estimated as required for the withdrawal has been consumed.—*New York Medical Journal*, March 7, 1891.

The Leprosy Commission.

The Indian correspondent of the *Medical Press*, March 4, 1891, furnishes the following particulars regarding the work of the Leprosy Commission: The Commissioners arrived at Bombay in November, 1890, and at once proceeded with their inquiries in that city, whence they proceeded to Madras, the Central Provinces, Hyderabad and Burma. They have yet to go through Bengal, the North-West Provinces, and the Punjab. This, however, in itself constitutes little more than half the inquiry, and which consists in making the round of the several leper asylums and examining the various patients confined therein. A good deal of time was necessarily spent in getting at the family history and the extent to which members of the family suffered from the disease, and who for the most part are scattered about. In Burma a rather different course was taken, the lepers were collected from the country and from the pagodas. In Prome a house-to-house visitation was made, and a number in this way were got at. A visit was suggested to the mosque at Tollygunge, where on the first Thursday in each month alms are distributed to about 600 paupers, the great majority of whom are lepers. This, however, was obliged to be abandoned, owing to want of sufficient time, but at Hyderabad an opportunity occurred of collecting evidence from a very similar gathering of lepers of the district. Here it appears that a wealthy native gentleman periodically distributed considerable sums of money among the lepers, and hearing of the arrival of the Commissioners in the city, he at once let it be known that he would distribute alms on a certain day, and this proved of great value. The Commissioners were last heard of in Calcutta, where upwards of fifty lepers were thoroughly examined the first day and their family history carefully ascertained. After having completed their work there, they will then proceed to Darjeeling and to Burdwan, and thence to the orphanage at Purulia. Of equal, if not in some respects of greater importance, is the bacteriological laboratory work which must follow on the footsteps of the inquiry, and which will have to be done at Simla, and will, it is believed, occupy about six months. The work there will, for the most part, consist of microscopical examination of the various diseased structures, the separation and cultivation of the leprosy bacillus, and to what extent it may prove to be the medium of communication. On this point some of the members of the Commission retain a perfectly open mind.

Extra Titles.

The *Medical Record* says editorially, March 7, 1891: "The use of extra and distinctive titles for medical men has always provoked discussion among those who have and those who have not the coveted appendages. The recent action of the Toledo Medical Association in resolving to dispense with all extra insignia of rank brings the general subject again to notice. While much can be said on both sides, we confess ourselves in favor of such extra titles as guarantee the possession of extra knowledge or ability. It may sometimes be the question which is the greater, the man or his title, the officer or the office, the professor or the college, the surgeon or the hospital, and so on. Few men are so celebrated as to carry with their work the simple name as

sufficient authority for *ex cathedra* statements. There are too few Hannibals, Cæsars and Napoleons in our profession to make precedents in such a line. Consequently, when a man claims a right to speak from his experience, it is proper to prove his fitness by stating his position and title. But the latter must be distinctive, if it adds force to the arguments and statements of an author or teacher. We admit that such distinctions are invidious, but all distinctions are invidious. Because they are so, men are willing to work and struggle for them, and in so doing make themselves fit the positions when they attain them. We are well aware that the man of mere titles means nothing. Those of professor are in some quarters so common that it becomes a real distinction to be a high private. The fellowships to societies are too numerous to mention, while the medical air is literally swarming with buzzing dispensary assistants. There is a happy medium between the two extremes of magnifying an office or of abolishing it altogether. It becomes after all a matter of taste with each man when and how to name his titles. There is as much presumption sometimes in avoiding their use on the egotistical plea that the name itself is sufficient as there is in making the tail too heavy for the kite. At all events, we cannot legislate on taste or expediency in this matter, and we very much fear that the resolutions of the Toledo Medical Association will be whistled down the wind."

[This is very true. The use of titles is sometimes ridiculous, but the fact that a writer holds a position of responsibility as a teacher or practitioner adds to the force and value of what he says; and, until an author may assume that all medical readers know this fact, it is proper to use a title which will acquaint them with it.—Ed. Reporter.]

Gastric Function in Chronic Nephritis.

In the *Bolnitchnaia Gazeta Botkina, No.* 47–52, 1890, Dr. V. Kravkoff publishes an exhaustive paper on the gastric function in chronic nephritis, giving in a tabulated form the results of his experiments on the gastric function of patients with renal affection of different degrees. He states that free hydrochloric acid in the stomach of patients with chronic kidney affections is extremely variable in different cases, as well as in the same case at different times. The variation in different patients is more marked, and its relation to the general clinical symptoms is less marked than that in the same individual. In the latter case the fluctuation is relatively less marked, but its relation to the general condition of the patient is much more conspicuous. In the majority of cases the absolute amount of free hydrochloric acid is lowered, the general acidity remaining the same. In the minority, the amount is normal or absent, but the general acidity is lowered. The absorptive power of the stomach is normal, as a rule. The gastric motor power is lowered only in especially cachectic cases, or cases with pronounced gastro-intestinal catarrh. Sub-acute and chronic attacks of uremia do not necessarily interfere with the presence of a normal amount of hydrochloric acid in the gastric juice and the normal digestive power of the latter.

Medical Schools in New York.

The *Medical Standard*, March, 1891, says: The recent incorporation of the New York College of Physicians and Surgeons with Columbia College has very naturally led to medico-historical reminiscences. It appears that in 1767 Columbia College established the first medical college in New York State. In 1769 the graduation of the students awakened such public enthusiasm that the New York Hospital was founded. The Columbia medical department survived until the outbreak of the revolutionary war when all college work ceased. The Medical College remained moribund until 1806 when the College of Physicians and Surgeons was started. It had no faculty to speak of, but the Columbia medical department had, and this medical faculty was transferred to the College of Physicians and Surgeons which, however, maintained a separate existence. In 1860 a nominal union was secured. The present union is, however, an intimate one. The medical college retains its name, but becomes an integral part of the university system of Columbia. The treasurer and trustees of Columbia assume all financial and other functions hitherto exercised by the same officials of the medical college. Dr. McLane becomes dean of the medical department and one of its representatives in the university control. The income of Columbia is to be drawn on for the support of the medical department. The students matriculate as students of Columbia.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

ELECTRICITY FOR THE DISEASES OF WOMEN.

Much interest has been felt, by thinking men, in the question as to the value of electricity as a curative agency in gynecology. This question has been kept constantly before the profession by the electricians themselves; and as the importance of the subject demanded, a respectful hearing has been given. It cannot be denied that at the present time the profession is disappointed with what has been accomplished by electricity. Only recently it was claimed that electricity was a positive cure for ectopic pregnancy and for many cases of pelvic inflammation, including the various forms of salpingitis and that pelvic adhesions, binding bowels, uterus, ovaries and tubes together, melted like the snow before the summer sun. Now, we hear this no more, or it is only hinted at, or it is hoped that electricity will do these things. Practically, the use of electricity is condemned by conservative men in the treatment of ectopic pregnancy and in all the graver forms of pelvic inflammation. Electricity has failed to abolish the necessity for abdominal section in ectopic pregnancy, and in the various septic accumulations in the tubes and ovaries.

It was claimed that electricity would displace hysterectomy and the removal of the uterine appendages, in the treatment of fibroids; that it would cure symptomatically and anatomically. The proof of this claim has been anxiously awaited, and it is gratifying to record that there is a growth of evidence of the value of electricity—the galvanic current—in the treatment of this disease. The Keiths have shown, positively, that electricity will do much for the relief or cure of fibroid tumors. At the present time it has not supplanted hysterectomy or the removal of the uterine appendages; but has been established as a method of treating uterine fibroids. Careful men exclude it in the treatment of fibroid tumors in which salpingitis exists—a considerable class, of soft myomata, and of fibro-cystic tumors. When it is recalled that most fibroid tumors do well without special treatment, that the occasional use of the curette will suffice in the treatment of many others, and that only a small percentage have been submitted to section in the past, it will be admitted that the field of usefulness of electricity in the treatment of fibroids is not a broad one.

There is no doubt, however, that the galvanic current, properly used in the treatment of uterine fibroids, will arrest hemorrhage, will lessen pain and will, at times, bring about a diminution in size or even the disappearance of the tumor. These facts have been established by thoroughly reliable men and are incontestable. On the other hand it must not be forgotten that in the natural history of fibroid tumors, hemorrhage at times lessens or ceases spontaneously, that pressure and reflex pains vary from time to time, and that the tumors

themselves diminish or disappear at times spontaneously. And also it must be remembered that certain dangers attend the use of the agent. Deaths have been reported; peritonitis has been caused, and growth of the tumor has been accelerated. There is thus a negative side to the question.

It is yet to be decided in what class of fibroids electricity will do the most good, and what the dangers of its use really are. Then its advantages and disadvantages in the treatment of a special class of fibroid tumors, can be compared with the advantages or disadvantages of hysterectomy in the same class of cases.

Electricians claim to cure otherwise incurable cases of chronic metritis and endometritis. These conditions, as primary, uncomplicated diseases, are rarely met; usually they are found as a minor complication of salpingitis—perhaps antedating or causing the salpingitis, but later being kept up by the tubal inflammation. In the rare, uncomplicated form of these uterine maladies, and in purulent endometritis sometimes remaining after the removal of the uterine appendages the use of the galvanic current is indicated if simpler measures fail. When the uterine disease is but a complication of salpingitis, all intra-uterine treatment is contra-indicated.

It is gratifying to be able to call attention to the lecture by Dr. Fisher, on the use of "Galvanism in the Treatment of the Diseases of the Uterus" in the last issue of the REPORTER, which, on the one hand, adds something positive to the literature of the subject, and, on the other, serves as an illustration of the views already expressed. Dr. Fisher is to be congratulated on much that is in his lecture. He has demonstrated something—that in certain cases the use of the galvanic current has controlled uterine hemorrhage, that in one case a fibroid became smaller after the use of the current for a year, and that in another a so-called vaginismus disappeared. He states, also, that he has obtained good results in ten cases not reported.

Dr. Fisher has demonstrated that galvanism will control uterine hemorrhage from certain cases of fibroid tumor and from abortion, after the failure of all medical means. No mention is made of the curette; and the question arises: would not these women have been cured with the curette in a few minutes, instead of in weeks or months by the use of electricity. And again, it is disappointing to those who have hoped much from the use of electricity, to find that in a large clinical service, like that at the Jefferson College, in a whole year's work but twenty women have been benefited. How many have been treated without benefit, the reader is left to conjecture. And, finally, we find that peritonitis has been induced by electricity in the hands of one so careful as Dr. Fisher.

The subject is certainly in an experimental state at the present time, and what is needed is careful reports of actual work, care being taken to make diagnoses as exact as possible. With full reports of good and bad results obtained by the workers in this field, the profession will be enabled to assign to electricity its true value as a therapeutic agent in the treatment of the diseases of women.

EXCISION OF THE VERMIFORM APPENDIX IN APPENDICITIS.

The inflammatory diseases in the region of the cæcum, described usually under the names typhlitis and perityphlitis, are of very great interest. Typhlitis is generally the result of fecal impaction, and it yields readily to medical treatment. The condition described as perityphlitis is probably in nearly all cases due to an inflammation or rupture of the vermiform appendix; appendicitis is, therefore, a better name for it. In it, also, medical treatment is in the majority of cases sufficient; but there are a number of cases in which an operation is the safer

course to pursue, and a still fewer number in which the only hope of saving life is to be found in a successful operation.

The *British Medical Journal*, February 21, 1891, gives a brief account of four cases of appendicitis in which Mr. J. B. Sutton operated and excised the appendix. The first patient was a man, twenty-two years old, with unmistakable appendicitis. Mr. Sutton exposed the cæcum by a lateral operation, and found the appendix lying adherent to the anterior aspect of the cæcum. The middle third of the appendix had sloughed, and an abscess, containing several ounces of pus, had formed as the result of it. The appendix was removed, the stump sutured and the peritoneal cavity flushed with warm water. The patient made an uninterrupted recovery.

The second case illustrates the difficulty attending the diagnosis of appendicitis. The patient had had three previous attacks, and came under Mr. Sutton's care as a case of renal colic; the disease was really relapsing appendicitis. On exposing the cæcum by a lateral incision, Mr. Sutton found the appendix slightly adherent to the brim of the pelvis; its lumen was obstructed, and below the constriction the appendix was filled with pus. The appendix was cut off, and the end was carefully sutured. The patient left the hospital convalescent on the fourteenth day.

The third case had also been regarded as one of renal colic, but Mr. Sutton came to the conclusion that the patient had a post-cæcal abscess, probably secondary to inflammation of a vertical retro-cæcal appendix. This clever diagnosis was verified at the operation; the appendix was lying vertically behind the cæcum, and its middle third had sloughed. The pus was washed away, the stump of the appendix sutured and a drainage-tube inserted. Convalescence was interrupted by an attack of pleurisy, which suggested that the trouble with the appendix was tubercular; no bacilli, however, could be found in cut sections of the appendix.

In the fourth case, the patient had been admitted with typical signs of typhlitis. Under medical treatment he seemed to improve, but in the course of three weeks the presence of pus was clearly indicated. At the operation, a large quantity of pus was evacuated from the iliac fossa; the tip of the appendix had sloughed.

The first, third and fourth of Mr. Sutton's cases are cases in which death would have resulted, in all probability, if an operation had not been performed. There is no dispute as to the propriety of operation in such cases. In the second case, one of relapsing appendicitis, there is still a wide difference of opinion as to whether or not an operation is the best method of treatment. Undoubtedly, in a number of cases, a patient gets entirely well after repeated attacks of appendicitis. If the recurrent attacks are not severe, if they appear to decrease in frequency and lessen in intensity, and if the patient is so situated that he can go to bed when they occur, without serious loss or inconvenience, it is probably best to employ medical and hygienic treatment alone. But if the attacks show no tendency to subside spontaneously, and at the same time are a cause of serious loss and disability to the patient, an operation may be advised. The operation should be performed in the interval between attacks.

Unquestionably lives are lost in cases of typhlitis and appendicitis because an operation is not done at the proper time and in the proper way. But, if Mr. Treves is right, the result would be worse if all cases were subjected to operation. Mr. Treves, who is a distinguished surgeon in this special field, says that, at the London Hospital, nearly all cases of typhlitis recover under ordinary medical treatment, and that only a few cases of appendicitis in young persons require operation. Probably no cases, he says, should be operated on before the fifth day, for cases of death on the third or even the fourth day are almost unknown. Contrary to the impressions one receives from reading the opin-

ions of many writers on this subject, Mr. Treves declares that the operation of removal of the appendix is often very difficult even during a quiescent period. He thinks that some day a portion of the ureter will be removed for an appendix.

Approval of medical treatment for most cases of typhlitis and appendicitis, coming from such a surgeon as Mr. Treves, means far more than it would if it came from any purely medical man; and yet Mr. Treves only gives expression to what is the common experience of most physicians. The chief difficulty which the latter encounter is to decide when medical treatment should end and surgical aid be invoked. The decision in a doubtful case requires close observation, large experience and ripe judgment. We think it would be wise for the physician to consult with a surgeon while the propriety of operating is still in doubt, and not to wait until it becomes clear to every one that an operation must be performed; for, in this as in most other cases, if an operation is required, the sooner it is done the better the chances of success.

HERPES VACCINIFORME OF INFANTS.

There occurs at and about the genital region in infants of three or four months an eruption, which, at first vesicular, soon ulcerates and presents the appearance of a mucous patch. The condition is a rare one, and derives its importance from its close resemblance to the secondary eruption of heredity syphilis, for which it is commonly mistaken. Fournier, who describes the affection in the *Bulletin Médical*, January 28, 1891, has seen only ten cases, and gives the condition the name of herpes vacciniforme by which it is, perhaps, best known. The eruption may appear coincidently in an infant born of syphilitic parents, but in other cases it is followed by no sequelæ. It occupies usually folds of the skin, where adjacent surfaces come in contact. In the first stage, the vesicle resembles that of vaccinia before the period of suppuration. The spots may be isolated or occur in groups or become confluent. In the second stage, umbilication and rupture take place, with subsequent ulceration. The resemblance is strong to a mucous patch. The affection is usually purely local. Occasionally, however, there is involvement of adjacent glands. Without treatment, the eruption may continue indefinitely. Under appropriate management, it may disappear in eight days. Relapses may occur, and the duration may be prolonged for from a month to six weeks. The process is thought to be the result of local infection from the bowel, in consequence of diarrhœa, which often coexists.

The treatment requires absolute local cleanliness, baths of simple water, of bran, or of starch, the application of lotions of boric acid or of diluted Labarraque's solution, a drying powder of bismuth, of oxide of zinc, of salol, or of iodoform, and a cotton dressing covered by some impermeable material.

UNIVERSITY OF MICHIGAN.

It is reported that the bill making an appropriation for the Ann Arbor University during 1891–2 was tabled in the Senate of Michigan, on April 2, to save it from defeat. It was opposed by the farmer members on the ground that "a horde of foreign pupils were being educated at the expense of the poorer taxpayers of the State."

It is to be hoped that this action will be but temporary, and that there will be no impairment of the usefulness of the medical department of the University of Michigan, which has done such excellent work in preparing men for the practice of medicine. The fact that its existence and success did not depend upon the fees of students has enabled it to take a high stand in regard to medical education, and to establish and adhere to a graded four years' course of study. We trust that, in their wisdom, the farmers of Michigan will come after awhile to see

that education is worth paying for, and that, within certain limits, the larger the class at their University, the better for it, and the better for each student; so that it is no disadvantage if some persons outside of the State come there to get an education without charge for tuition. It would be easy to show, from a purely economic standpoint, that it is a pecuniary advantage to Ann Arbor and the State of Michigan to get as many students there as possible, and even to make no charge for teaching them. Were this otherwise, it would still be a very good thing to have large classes at their University, for the good of the people of that and neighboring States.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

PLAIN TALKS ON MEDICAL ELECTRICITY AND BATTERIES. By Horatio R. Bigelow, Fellow of the American Electro-Therapeutic Association. Small 8vo, pp. 85. Philadelphia: P. Blakiston, Son & Co., 1891.

This little book contains a great deal of succinct information in regard to a subject about which most doctors have very hazy notions. The first part is occupied with definitions of terms like, "volt," "ohm," "ampère" and "potential," which must sometimes be troublesome to the general reader, when considering articles in which electricity is discussed. To know what they mean is not common, except with electrical experts; and so it is no reflection on the readers of the Reporter to intimate they might get useful information in Dr. Bigelow's book. Besides this, the book contains very fully and well illustrated descriptions of a variety of electrical machines, and diagrams showing the points on the surface to which electricity is applied for various medicinal purposes, and a therapeutic index in which there is given in alphabetical order a list of diseases and conditions for which electricity is used, with the form of current and the made of application.

MANUAL OF CLINICAL DIAGNOSIS. By Dr. Otto Seifert, Privat-docent in Würzburg, and Dr. Friedrich Müller, Assistant der II. med. klinik im Berlin. Translated from the fifth German edition, enlarged and revised, with the permission of the authors, by William Buckingham Canfield A. M., M. D. (Berlin), Lecturer on Clinical Medicine, and Chief of Chest Clinic, University of Maryland, etc. Second edition, revised and enlarged, with fifty illustrations and one colored plate. Small 8vo, pp. xi, 185. New York and London: G. P. Putnam's Sons, 1890. Price, $1.50.

This book treats, in successive chapters, of the blood, the temperature, the organs of respiration, the sputum, laryngoscopy and rhinoscopy, the circulatory system, the pulse, the digestive and abdominal organs, the urine-producing system, transudations and exudations, parasites, the nervous system, analysis of the pathological concrements, and metabolism and nutrition.

Those who expect to find in the book a treatise on medical or physical diagnosis, will be disappointed. Relatively little space, for example, is given to the examination of the heart and lungs, and, perhaps for this reason, some of the statements are unsatisfactory and others wrong. We object to the assertion that "very strong bronchophony is called pectoriloquy. In pectoriloquy there is not simply exaggerated reproduction of the voice sounds, but the individual words can also be distinguished. Again, in saying that heart murmurs are transmitted more easily in the direction of the blood-current, the authors give expression to a general and useful rule; but they are wrong when they say that the systolic murmur of mitral insufficiency "is heard most distinctly at the second costal cartilage of the left side." The systolic murmur of mitral insufficiency is heard best at the apex, or a little external to the apex, and it is transmitted to the axilla; in very exceptional cases it is most intense at the second left intercostal space.

The chapters on the blood, the digestive and abdominal organs, the urine-producing system, parasites and the nervous system are all very good. The book as a whole is an excellent one to put into the hands of a third or fourth year student who already knows ordinary medical diagnosis. It will also prove very valuable to a hospital interne who has a liking for clinico-pathological study; but it is too advanced to suit the requirements of the beginner.

TRANSACTIONS OF THE AMERICAN ORTHOPEDIC ASSOCIATION. Fourth Session, held at Philadelphia, Pa., September 16, 17 and 18, 1890. Volume iii, 8vo, pp. xxiii, 242. Philadelphia: Published by the Association, 1890.

This volume contains the papers read at the fourth annual meeting of the Association, at Philadelphia. It was one of the most successful meetings the Association has held. In addition to an admirable address by the President, Dr. De Forest Willard, there were twenty-three papers read. One of the most interesting features of the programme consisted in a series of papers on Lateral Curvature of the Spine, by Drs. Benjamin Lee, of Philadelphia; Charles L. Scudder, of Boston; Robert W. Lovett, of New York, and A. B. Judson, of New York. An extremely interesting and animated discussion followed the reading of the papers.

The Association is to be congratulated upon its thriving condition and upon this last volume of transactions, which bears such ample testimony to the progress orthopedic surgery is making in the United States.

Insoluble Cement.—It is said that a cement which is hard enough to withstand even boiling sulphuric acid may be obtained by gently melting India rubber and adding 8 per cent. tallow while stirring. Sufficient slacked lime should be added to give to the compound the consistency of a soft paste. Twenty per cent. of vermilion is now added, which causes the mass to harden immediately.

Notes and Comments.

Contagiousness of Gonorrhœa.

In discussing the contagiousness of chronic urethral discharges, in the *Journal of Cutaneous and Genito-Urinary Diseases*, March, 1891, Dr. George Emerson Brewer, of New York, says the practicing physician is frequently called upon to answer inquiries regarding the limit of the contagious stage of gonorrhœal urethritis. The question is a serious one, especially when considered in its relation to marriage, and should be regarded as equal in importance to that of syphilis.

It has not infrequently been Dr. Brewer's experience to be consulted by young men, a few weeks or months before a contemplated marriage, with a history of one or more attacks of gonorrhœa in former years, and who believed themselves to be well; yet who upon a careful examination presented the unmistakable signs of a chronic urethritis. The only evidence of disease remaining in these cases frequently was the presence in the urine of small thread-like bodies, to which the name of *Tripperfaden* has been given by the German surgeons, who first described them and demonstrated their importance. These minute shreds are composed of mucus, pus and epithelium; and represent the secretions which adhere to any granular patch or area of chronic inflammation remaining on the urethral mucous membrane.

In consulting the standard authors upon the subject of genito-urinary diseases, one is impressed by the marked difference of opinion, regarding the contagiousness of chronic urethral discharges, held by those whose reputation and experience entitle them to the foremost position in the discussion of this question. As early as 1785 Kühn called attention to the fact that the discharges resulting from a gonorrhœa remained contagious so long as they contained pus. The opposite opinion was held by Hunter, who denied the possibility of contagion from the gleety discharges of a chronic urethritis. This view was also shared by Bell and Ricord. In a paper entitled "Gonorrhœa a Non-specific Disease," published in the *New York Medical Independent* in 1864, A. K. Gardiner strenuously denies the contagious element in any, save the discharges from the most acute stage of the disease; and says regarding gleet that it is "allowably benign and innocous." Noeggerath, on the other hand, in a paper published in 1872, concludes that a man who has once been the subject of a gonorrhœal urethritis, never fully recovers, that the disease invariably lingers in the glands and ducts emptying into the canal, and may at any time furnish a secretion which may infect those with whom he has sexual relations. He also states that nine-tenths of all women married to men who have had gonorrhœa, sooner or later become the subject of incurable and painful inflammatory disease of the uterus, tubes or ovaries; that this infection may take place rapidly, and manifest itself as an acute affection, or by means of a slow and unrecognized process to which he gives the name of "latent gonorrhœa." In a subsequent paper, read before the American Gynecological Association in 1876, the author reiterates these opinions, and adds that 90 per cent. of all cases of sterility can be directly traced to gonorrhœa.

Without entering into any discussion regarding the correctness of these views, which have been the object of considerable criticism, the fact remains that these papers had the effect of calling attention to a source of female disease and suffering, the importance of which had not, until their publication, been adequately recognized. This difference of opinion upon so important a question is hardly to be wondered at, when we consider that at the time these views were enunciated, nothing definite was known regarding the etiology of this disease. Since the discovery by Neisser, in 1878, of the gonococcus, and the (Dr. Brewer thinks) establishment of its relationship to this disease, but one opinion can logically be held by those who accept his theory of gonorrhœal inflammations, and that is, that all secretions containing this micro-organism are capable of transmitting the disease under favorable conditions. In his recently published work upon this subject, Ernest Finger emphasizes this point and states regarding marriage, that it should be absolutely prohibited in all cases where the existence of a chronic urethritis is evidenced by the presence of the "morning drop" or *Tripperfaden* in the urine, until the following facts have been established:

1. That after from two to four weeks of daily observation, the secretions from the urethra are found to be *free from pus and made up wholly of epithelial cells.*

2. That no gonococci can be detected by

the microscope, even after a purulent discharge has been established by the employment of irritating injections of corrosive sublimate or nitrate of silver; and

3. That neither prostatis nor stricture exists.

Dr. Brewer says that upon first becoming acquainted with the views expressed by Finger, he regarded his conditions as unnecessarily severe, and his opinion of the danger as greatly exaggerated. But a somewhat remarkable case, which came under his observation, illustrated in a most striking manner the fact, that unless some of the precautions advised by Finger had been insisted upon, the responsibility of a dangerous illness would justly have rested upon his head. The case is reported by Dr. Brewer, and fully justifies the inferences he draws from it.

Pasteur and his Work.

The *American Practitioner and News*, February 14, 1891, says editorially: At a moment when Pasteur has been apparently promoted to a secure apotheosis, and new eligibles are being sought to share with him the superabundance of divine honors, it comes like a discord in a grand orchestra for men eminent themselves to stand out and boldly declare to the world that the renowned savant is wearing unearned laurels. But that is just what has been done by two eminent Paris physicians, one of them Dr. Lutaud, editor of a leading medical journal, the *Journal de Medicine de Paris*, and the other Prof. Peter, member of the Academy of Medicine. They not only charge Prof. Pasteur with exploiting procedures in themselves worthless, but with exploiting them for gain, and with interfering in political matters for the purpose of unfairly promoting his personal interests.

In a book of some four hundred and forty pages, a second edition of which has just been published by Dr. Lutaud, the whole history of the Pasteur discoveries has been gone over, as indeed they have been from time to time in the author's journal. In the first place, the originality of the discovery that repeated inoculation may confer immunity is denied to Pasteur.

In 1821 Magendie published in his *Journal of Physiology* a series of experiments proving that by successive inoculations hydrophobia limited itself after the third generation or repetition in different animals. These experiments with their results were republished in Paris in 1868, in a work entitled *What to do till the Doctor comes.*

In 1879 M. Galtier, professor in the Veterinary School of Lyons, wrote a communication to the Academy of Sciences announcing that he had discovered that rabies is transmissible to rabbits, and that they thereby become a convenient and harmless instrumentality for determining the virulence or non-virulence of various fluids derived from rabid animals.

In 1879, in April, Dr. Deboué, of Pau, communicated to the Academy of Sciences, through M. Bouley, a treatise on hydrophobia, in which he declared his conviction that the destination and seat of the rabic virus is the medulla.

Pasteur is a member of the Academy of Sciences to which these communications were made. So much for originality.

Passing over the charges in which Pasteur is made to take part in the working of political machinery to promote the election of Paul Bert over Davaine to membership in the Academy of Sciences, for the purpose of securing through M. Bert large government bounties, and to which there may be two sides, we come to the actual status of the several discoveries in the matter of inoculation.

It is shown that Pasteur had made a contract to sell for 1,000,000 francs the total rights of sale of the modified virus of charbon, which fell through because the syndicate could not raise the money, and because at the time confidence was being lost in it and the sales were diminishing; and this while it was stated by M. Paul Bert in the Chamber of Deputies that Pasteur had nobly refused, and declared that since he was receiving a pension from the State his works belonged to the State.

It is now a fact current that inoculation against charbon has gone out of date, the general impression being not only that it is not permanently of value, but that it is even dangerous and destructive. The outcome in chicken cholera and the rouget of pigs has been about the same.

The process invented by Pasteur to further the manufacture of beer of fine quality in France, and which was in its turn heralded as a great addition to the sources of wealth available for France, has been absolutely abandoned.

His labors with the silk-worm have not prevented the steady decline of silk culture in France, the official statistics showing that

from 17,000,000 to 18,000,000 of kilograms of cocoons were produced in 1865, when he gave out his discovery for the protection of the silk-worm. The amount has steadily declined to 3,000,000 or 4,000,000.

But what of the protective measures against hydrophobia, the crowning task of all the works of the great chemist? Dr. Lutaud shows beyond all cavil, by government statistics and hospital statistics that are accessible to all, that from 1850 to 1872 inclusive there was a total of 685 deaths from hydrophobia in France, or an annual average of 30. Seventeen died without treatment in France in 1886, and 22 with treatment. From November 1, 1886, to November 1, 1887, 27 died under treatment; 23 in the year ending November 1, 1889, and 21 in 1889—a reduction from the former average of about 5 per annum. In the year ending November 1, 1886, 1,538 persons were treated for bites by rabid dogs. Claiming with Le Blanc that 16 per cent. of all persons so bitten become hydrophobic, this would give for that single year 246 cases of hydrophobia that would have been but for Pasteur's treatment. But it happened that 16 of these cases died, so that there were 230 lives saved by the Pasteur treatment!

Dr. Lutaud shows further that the number of persons dying of hydrophobia has steadily gone down in all other countries besides France without treatment, and that in some of them it has become a thing unknown. Can we then think Dr. Lutaud too bold in declaring that Pasteur's system of inoculation actually tends to spread hydrophobia in France? This apprehension is further strengthened by the fact that many of these are cases of paralytic hydrophobia, which is the hydrophobia, as a rule, of inoculation.

It matters not how much the world may be dazed by the brilliant name of Pasteur or how much misled by blinded partisans, there is no escaping the principal conclusions of Dr. Lutaud in this matter. For to believe that, while in all other countries hydrophobia is decreasing, in France, beginning exactly with the discovery of a supposed preventive, there should happen in that country enough cases to allow nearly three hundred a year to be cured, and still leave a much larger number than the statistics of the country are entitled to when compared with those of other lands!

We would not rob Pasteur of a leaflet of his merited laurels. He is one of the great men of time, whatever critics closer to him may be led to feel when they see him wearing unmerited honors. He has made discoveries and given a stimulus to discovery that will resound onward through the years to come; but that is no reason why the whole world should fall down in worship of men like themselves and be made blind to the most glaring inconsistencies. And while we honor Pasteur, we honor Lutaud and Peter, who, in the glamour of hero worship, still have the discernment and the courage to speak what they regard as the truth.

New Operation for Lacerated Perineum.

Dr. Alexander Duke, Gynecologist to Steeven's Hospital, writes in the *Montreal Medical Journal*, March, 1891:

I wish to bring before the notice of my gynecological brethren an operation I have designed for the restoration of a lacerated perineum, easy of performance, and which will, when properly executed, form a good perineal floor, and I might almost say practically a new perineal body. The patient, having been prepared by the usual preliminary steps required for the old operation when under the influence of an anæsthetic, is placed in the lithotomy position, the left index finger being introduced almost its entire length into the rectum, a long, straight, double-edged bistoury is made to pierce the tissues *in front of the anus at right angles to the vulva*, and, guided by the finger in the rectum, is made to penetrate the septum for two and a half inches upwards, the incision being enlarged laterally to two inches as the knife is withdrawn. The patient is then turned on her side, and on the points of incision being pressed together, a lozenge-shaped opening will be seen, and when all sutures required have been introduced and are properly adjusted and approximated, the two cut surfaces are brought into direct apposition. The sutures are introduced by a strong cycle-shaped needle with eye near point, mounted on a handle, strong silver wire being the suture preferred. The needle is introduced at edge of incision, and, guided by a finger in the rectum, is made to travel under the cut surface to its full depth above, describing the arc of a circle; and on point of needle appearing *directly opposite*, it is threaded with suture and drawn through. On the ends of this suture being drawn together with the fingers, a good idea

can be formed of how many additional stitches may be required. When all considered necessary have been inserted, passed through leaden bars perforated at intervals, and approximated, a finger of each hand passed into the rectum and vagina will at once recognize the gain in thickness of septum, the external tissue being pushed fully an inch forward from anus, and forming a thick and solid perineal body. The incision being a deep one, on union taking place between the raw surfaces, a considerable amount of support must be afforded in cases where a pessary is required, or where there is much tendency to prolapse of uterus or vaginal walls. My experience of the operation though up to the present time limited, has satisfied me with the results, and there being *no loss of time whatever*, should the operation fail, it cannot add any difficulty to a subsequent one.

Even should the perineum be lacerated to verge of anus, what I describe can be done. I find that leaving the sutures for ten days is generally sufficient, but if I am in doubt as to the union being strong, I cut the wire, but leave it *in situ* for a day or two longer, thus affording some support, and relieving the strain on the edge of suture holes, and I also support the parts by long strips of adhesive plaster carried from hip to hip over new perineum. The wire should be stout and not too tightly twisted.

My friend, Dr. More Madden, has kindly given my operation a trial, and was much pleased with the results, especially in one of his cases where the old plan of operation had been tried previously but failed owing to the patient's poor state of health and a want of healing power.

The advantages of my plan of operation are briefly these:

1. The simplest of performance as yet proposed; no danger of hemorrhage, the surface, when dry, being brought together.

2. No danger of sepsis, as the incision is not open for the admission of any discharge from either vagina or rectum during healing process.

3. No loss of tissue, and consequently no harm done should the operation fail.

Calomel in Kidney Disease.

The general opinion that calomel is contra-indicated in renal dropsy is founded on the assumption that the drug acts on the epithelium of the kidney. When, therefore, the epithelium is considerably affected or partly destroyed, as in so-called parenchymatous nephritis, the mercury, by acting on the already weakened and scanty epithelium, would, presumably, do little good and possibly much harm. Rosenheim's experiments seemed to prove the truth of this theory.

The *Medical Chronicle*, March, 1891, asserts that Fleiner, in an article on the diuretic action of calomel in renal dropsy, in the *Berliner Klinische Wochenschrift*, December 1, 1890, says that he has found that facts are somewhat opposed to the general belief. Two years ago Prof. Erb gave a lecture on calomel as a diuretic, and mentioned a case of chronic parenchymatous nephritis with general dropsy, in which, after all customary diuretics and diaphoretics had failed, the œdema rapidly gave way under the calomel treatment, and the patient finally left the hospital with scarcely any appearance of anasarca. Fifteen months later she appeared again, and stated that all the intermediate time she had been able to work, and had not had dropsy to any great extent. Her disease now presented the characteristics of secondary contracted kidney.

This case made its due impression on Fleiner, then a student under Erb, and the case he details here with extraordinary preciseness and length is, so to speak, a twin of Erb's. The case was one of Bright's disease, threatening death from advanced dropsy. All other remedies proving useless calomel was exhibited in large doses, and *on two occasions in a few days* caused a marvelous improvement, the second time the œdema completely vanishing. Here, as in Erb's case, the patient, after the second treatment with calomel, had, as proved by his urine and the *post-mortem* (he died suddenly two months after), a contracted kidney, chronic parenchymatous and interstitial nephritis.

Influence of Exercise on Digestion.

Dr. Streng, in a lecture before the Medical Society of Giessen, on the Influence of Exercise on Digestion, which has been published in the *Deutsche Medicinische Wochenschrift*, states that he concludes from his own experiments that this influence is of a retarding nature. His experiments, however, suffer from the fact that he always injected 300

cubic centimeters of water before obtaining the contents of the stomach, so that the proportion between gastric juice and water continually varied. The first experiments in the clinic at Giessen were made on two dogs. Twenty-five grams of meat, suspended in 300 cubic centimeters of warm water, were twice injected into the fasting stomach, and after one feeding the dogs were compelled to remain for three hours in absolute bodily rest, while after the other feeding they were made to take active exercise. After the three hours the contents of the stomach were obtained and analyzed. The quantity did not essentially differ in the two cases; the experiments consequently tended to prove that exercise does not influence the time required for digestion. The chemical analysis also detected no difference. The same results were obtained by substituting the white of an egg for the meat. The experiments were then repeated twenty-five times on three men with healthy stomachs. Two of these suffered from sycosis, and the third from insipient muscular atrophy. They were fed each time with 200 grams of minced meat, a bun, a plate of bouillon and three spoonfuls of mashed potatoes, and the contents of their stomachs were obtained four hours and a half afterwards. The exercise after meals consisted partly in gymnastics, partly in walking; absolute rest was obtained in bed. These experiments gave the same results as those on the dogs, the difference resulting from the chemical analysis being especially imperceptible. The author therefore concludes that the gastric function is in no way influenced either by muscular action or by absolute rest.—*Lancet*, March 7, 1891.

"New Philadelphia."

"The New Philadelphia" is the title of a deeply interesting article which will appear in the May *Cosmopolitan*, and is from the pen of Mr. Henry C. Walsh. To those who are not entirely familiar with the "city of brotherly love" of to-day, and who, taking the joke-maker at his word, entertain the erroneous idea that this large city is at best but a sleepy and unenterprising town, the *Cosmopolitan's* article will prove a veritable revelation. The great change that has been wrought during the past decade in the external appearance of Philadelphia is ably set forth, and greatly augmented by the splendid illustrations drawn by Mr. Harry Fenn. A glance at these masterly drawings shows that, in beauty of architecture, the solidity and modernness of construction and design in her homes, clubs and commercial buildings, Philadelphia stands at the very head of flourishing American cities. The business, social and intellectual advancement of this, perhaps the most habitable of cities, is no less marked that is its mere outward progression. Doubtless, too much attention has been paid to other more ostentatiously progressive cities, especially of the West, to the exclusion of the Quaker City and its marvelous growth. The article in the May *Cosmopolitan*, however, places Philadelphia before the public in its true light as one of the best governed, most enterprising and socially, commercially and politically, progressive cities of the United States.

Local Sweating of Reflex Origin.

The *New York Medical Journal*, March 28, 1891, quotes from the *Journal de médecine et de chirurgie* for October, 1890, the following curious observation by Ducorneau: A young woman of good constitution had been confined two months previously. She had noticed for about two weeks that whenever she put her baby to the breast there broke out suddenly a profuse sweating of the thigh and leg of the side corresponding to the breast nursed. The sweating extended posteriorly from the nates to the foot, and lasted through the whole time of the nursing. The same phenomena was observed when the other breast was given. On changing the baby from one breast to the other, the sweating began and ceased always at the same moment with the flow of milk from the side in question. The mother had been considerably reduced by the sweating. Tonics were given and the breasts were rubbed with belladonna ointment. After a few days of this treatment the sweating diminished and finally ceased entirely. Ducorneau attributes the sweating to reflex action, though the *modus operandi* is difficult to explain.

Powder for Migraine.

℞ Citrate of caffeine . . . . . gr. 1½
Phenacetin . . . . . gr. 2
Sugar of milk . . . . . ʒi
To be taken every two hours until relieved.

CH. MARCHAND'S

PEROXIDE OF HYDROGEN

(MEDICINAL) H_2O_2 (Absolutely Harmless.)

Is rapidly growing in favor with the medical profession. Is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a Nostrum.

A REMEDY FOR DIPHTHERIA; CROUP; SORE THROAT, AND ALL INFLAMMATORY DISEASES OF THE THROAT.

OPINION OF THE PROFESSION.

Dr. E. R. Squibb, of Brooklyn, writes as follows in an article headed "On the Medical Uses of Hydrogen Peroxide (*Gaillard's Medical Journal*, March, 1889, p. 267), read before the Kings County Medical Association, February 5, 1889:

"Throughout the discussion upon diphtheria very little has been said of the use of the Peroxide of Hydrogen, or hydrogen dioxide; yet it is perhaps the most powerful of all disinfectants and antiseptics, acting both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. The few physicians who have used it in such diseases as diphtheria, scarlatina, small-pox, and upon all diseased surfaces, whether of skin or mucous membrane, have uniformly spoken well of it so far as this writer knows, and perhaps the reason why it is not more used is that it is so little known and its nature and action so little understood. . . . Now, if diphtheria be at first a local disease, and be auto-infectious; that is, if it be propagated to the general organism by a contagious virus located about the tonsils, and if this virus be, as it really is, an albuminoid substance, it may and will be destroyed by this agent upon a sufficient and a sufficiently repeated contact. . . . A child's nostrils, pharynx and mouth may be flooded every two or three hours, or oftener, from a proper spray apparatus with a two volume solution without force, and with very little discomfort; and any solution which finds its way into the larynx or stomach is beneficial rather than harmful, and thus the effect of corrosive sublimate is obtained without its risks or dangers. . . ."

Further on Dr. Squibb mentions that Charles Marchand is one of the oldest and best makers of Peroxide of Hydrogen, and one who supplies it to all parts of the country.

CAUTION.—By specifying in your prescriptions "**Ch. Marchand's Peroxide of Hydrogen (Medicinal)**," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon. Never sold in bulk.

PREPARED ONLY BY

A book containing full explanations concerning the therapeutical applications of both Ch. Marchand's Peroxide of Hydrogen (Medicinal) and Glycozone, with opinions of the profession, will be mailed to physicians free of charge on application. ☞ Mention this publication.

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

SOLD BY LEADING DRUGGISTS.

Laboratory, 10 West Fourth Street, New York.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{60}$ gr.), Atropiæ Sulph. ($\frac{1}{500}$ gr.), Codeia ($\frac{1}{60}$ gr.), Antimony Tart. ($\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{50}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonials from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

88 Maiden Lane, **New York City.**

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL and NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

CLINICAL LECTURE.

THE DIAGNOSIS AND TREATMENT OF CATARRHAL DYSPEPSIA.

BY JAS. M. ANDERS, M. D.,

PROFESSOR OF CLINICAL MEDICINE AT THE MEDICO-CHIRURGICAL COLLEGE; VISITING PHYSICIAN TO THE PHILADELPHIA AND EPISCOPAL HOSPITALS.

This man, A. P., 57 years old, is a printer. His family history is negative. His own history before the onset of his trouble is also negative, with the following exception. Eleven years ago he had a hemiplegia. Twenty years prior to this hemiplegia he had syphilis, *i. e.*, chancre followed by well developed secondary manifestations. The fact that the hemiplegia followed so long after the date of the appearance of the chancre renders it probable that it was due to cerebral syphilis. You will remember I told you while lecturing on that subject that syphilitic palsies were apt to occur from 10 to 20 years after the initial lesion; also that unless proper treatment was instituted at the proper time, changes would take place in the muscular and nervous tissues, which go on independently of the original cause and of specific treatment. Hence, from the history of this patient's case, I am inclined to think that the hemiplegia was due to the syphilis, which was probably not properly treated. He comes to us to-day for treatment for a different affection. For the last year he has vomited, regularly every morning on getting up, a couple of tablespoonfuls of ropy, tenacious mucus; his bowels have been regular. After eating he experiences a sense of burning weight and gastric uneasiness; he says he has no pain. Pain is not a symptom so constant in the inflammatory form of dyspepsia, from which, as I shall attempt to show, he is suffering, as one is led to suspect by writers on the subject.

Between the two forms, atonic and inflammatory dyspepsia, there are radical differences, hence the treatment must be radically different also; and yet there are symptoms and leading ones common to both. He says he has belching of gas, eructations causing heartburn, due to acids. On palpation he complains of tenderness over the cardiac end of the stomach, percussion elicits clear tympanitic resonance to the costal border, indicating no enlargement of the liver. His tongue has a yellowish white fur with red tips and edges and enlarged papillæ in the latter situation. This latter condition is almost pathognomonic of inflammatory dyspepsia. The tongue is either small with red edges and tip or it is broad and coated, especially in hepatic forms of the trouble, but the papillæ are always bright red and enlarged. The atonic form is due to conditions external to the stomach, and the symptoms are induced by reflex action, such as debility or anemia. In the inflammatory form the symptoms are caused by the local condition. Alcohol is a potent cause as well as immoderate eating, especially of spicy articles of food. He however tells us that he does not use alcohol and is a moderate eater. Of other causes predisposing strongly to this form are syphilis, gout, renal disease, paralysis, weak heart, even though no murmurs be present. In phthisis, gout, and syphilis, gastric catarrh is apt to be early induced. The subacute type of a passive nature is often produced by a weak heart or anything interfering with the return current of blood from the stomach. There is one symptom which is prominent in this case and which is not infrequently met with in chronic forms of inflammatory dyspepsia, namely, vomiting of ropy mucus in the morning when the stomach is empty. This is due probably to sluggish circulation—passive hyperemia. It is often hard to make a certain differential diagnosis between functional and inflammatory forms of the disease,

because many of the symptoms occur in both. Anemia and neurasthenic states are frequently associated with or are precursors of the atonic form; so too is a sluggish liver and constipation—in fact, anything which depresses the vitality of the system; but you do not have the history of syphilis, of gout, of renal, of lung or organic heart disease as in the inflammatory form. The symptoms which, though occurring in both forms, are more aggravated in the catarrhal form, are more constant. In atonic dyspepsia there is gastric uneasiness and a feeling of distention soon after a meal, rather than pain in the epigastric region, and this is the case in the majority of instances of the catarrhal form, though pain is sometimes patent in subacute gastritis. There is more acidity and thirst in the inflammatory variety. The tongue in the atonic form may be clean, or it may be coated with a yellowish or white fur. In the catarrhal form, it is sometimes small and clean, but is usually red at the tip and edges with enlarged papillæ, as in this case. The tongue is often broad, flabby, and coated heavily, but the papillæ are always pointed. Pain, as already intimated, occurs in both forms, though not in the stomach. In the atonic variety there is rarely much pain in the stomach. It may be between the shoulders or across the chest, often the pain is at the back of the head or at the forehead. In the catarrhal form pain is more apt to be felt in the stomach, but as a rule, only in the more acute forms, while in the subacute and chronic forms, pain in the region of the stomach is rare, but usually tenderness, as in this case. In the latter class of cases, pain is generally referred to the head.

In both forms of dyspepsia, alterations in the urine occur. Functional dyspepsia is attended with the presence of urates and phosphates in the urine. When the oxalates are present in abundance, the condition is often called oxaluria, and is frequently associated with a depressed state of the nervous system. In the catarrhal form, urates are present in large quantities, the sp. gr. is apt to be high, a condition of lithemia existing. In both forms the nervous symptoms are well marked, but to a greater degree in the catarrhal form. Patients suffering from inflammatory dyspepsia are apt to be gloomy, hypochondriacal, and suffer from these latter symptoms more than from those referable to the stomach. In the atonic form there are intervals of freedom from all symptoms, while in the catarrhal form the symptoms are constantly present. Drugs used with good effect in the atonic form will be found to aggravate the catarrhal.

In conclusion, I may say, to sum up the points on which to base a diagnosis in the catarrhal form, we have the history of gout, or of syphilis, or renal disease, or phthisis, or heart disease, as predisposing causes. As exciting causes, overfeeding, or improper food; malaria or alcohol. There is more frequent vomiting, more thirst, more heart-burn, more tenderness on palpation, more marked nervous phenomena, than in the atonic form. The condition of the tongue is to be carefully noted.

The treatment of the subacute inflammatory form, from which our patient is suffering, consists in giving the stomach rest, so as to save the mucous membrane and get rid of the waste products. For one or two weeks we will order milk diet, also order the time for feeding and quantity of food to be given. If it don't agree, we will give it pancreatinized or boiled, and to it a quantity of lime water may be added. Soon after feeding, give diluents, because the patient suffers from thirst; the best are mucilaginous substances and water, to which a few drops of muriatic acid should be added. Commence their administration one hour after meals, then every hour or two till digestion is complete. This allays thirst and produces comfort. When solid substances can be added, albuminous substances are better than farinaceous. After two or three weeks give one egg in the morning, a chop and rice or underdone beef for dinner for two or three weeks longer, along with the milk. Of remedies, we should select the alkaline carbonates and saline aperients. We will give this man every morning one drachm of Rochelle salts, to be taken fasting. If the patient can afford to go to a mineral spring, such as Carlsbad, so much the better. I shall also order the alkaline carbonates as per the following.

℞ Bismuth. subcarbonat. . . . . ʒii
Sodii bicarb. . . . . ʒiv
Ft. chart. No. xii.
Sig. One to be taken before each meal.

Attention to the patient's regimen is important. Order, in all cases, moderate exercise in the air, warm clothing, regular habits. After certain indications are con-

trolled and the local condition is much improved, enlarge the diet list and give tonics, beginning with small doses; otherwise the condition will be made worse. By the injudicious use of tonics, especially bitter tonics, this disease has actually been frequently produced. Don't forget to attempt to remove the constitutional cause that has led up to the case in hand, whether it be syphilis, gout or other conditions.

COMMUNICATIONS.

CARE OF THE CHRONIC INSANE.

BY THEODORE DILLER, M. D.,
PITTSBURGH, PA.

It is to be hoped that the bill recently introduced in the Legislature at Harrisburg, by Dr. Morton, president of the State Committee on Lunacy, providing for the erection of a hospital plant for the chronic insane will, with certain modifications, be approved of by the Legislature.

The normal capacity of the five State asylums combined is about 4,000; but they contain now about 5,250—or 1,250 more than their normal capacity. For the past five years the average annual increase in population in the asylums has been 238. Certainly no further arguments are needed to establish the fact that prompt and active measures should be taken to very considerably increase the State Hospital accommodations. The only question is: How shall the State build? In what shape shall the increased accommodations come?

Two plans have been suggested. 1. The extension of the present hospital plants by building additional wings or annexes to them. 2. By providing two new hospital plants—one for the chronic insane, the other for the criminal insane and insane criminals. (Note distinction.)

The adoption of the first plan assumes that the present hospital system is so good that it cannot be improved upon.

The promoters of the second proposition say: We can improve on the present hospital system. By our plan we can take care of 2,000 chronic insane better and much cheaper than they are now cared for. We can procure accommodations for all the insane criminals and criminal insane in a separate hospital plant at a cost to the State of not more than $3.66 per week (the present average rate).

Now if the claims embodied in the second proposition can be substantiated, certainly it behooves the Legislature to adopt them with as little delay as possible. Let us examine them a little more in detail.

Separation of the acute from the chronic insane has long been a *desideratum*. The great bulk of the insane are incurable. There are fully 3,000 inmates in the State asylums who are chronically insane beyond the smallest hope of recovery but who enjoy good, or at least fair, physical health. 1,500 or 2,000 of the most suitable of these would be removed to the new asylum. Here they would be put to work. From 80 to 90 per cent. of them would engage in profitable, or at least useful, occupations. A small infirmary building would suffice for those who became ill with intercurrent physical diseases. Those whose mental condition changed so as to render them no longer fit for the chronic asylum could be transferred back to one of the hospitals. Many of the methods and appliances now in use in the State Hospitals could be done away with in the new asylum.

The present State Hospitals were designed to treat the acute insane. Now, with the great bulk of the chronic insane and all the criminal class removed—with their machinery no longer clogged (if I may be permitted the expression), the existing hospitals would certainly be in much better working order. They might then become hospitals in fact as well as in name.

Now as to cost. The Lunacy Committee estimates that the new asylum will cost $600,000 or $300 per bed, and that the cost of maintenance will be $2.00 per week for each inmate—or $1.66 less per week than the insane are now supported for. The saving in cost of maintenance would in three or four years pay for the new hospital plant. The new asylum itself is not to be built after the fashion of the present hospitals, which the Lunacy Committee say "are characterized by unnecessarily elegant and expensive centre or administration buildings and by long, straight, cheerless wards, having small lodging rooms and dormitories opening into the same on either side; having a small ward dining-room in each corridor, and in many other particulars far behind modern ideas of proper hospital construction; being inconvenient to administer, and so planned as to but partially fulfil the pur-

poses for which they were erected. They cost anywhere from $2,000 to $3,000 per bed, and accommodate, for the sums expended, a relatively small number of insane."

The proposed asylum is to be several clusters of small buildings, two stories in height, plain and simple in their construction, conveying, as far as possible, the house idea and making possible a desirable classification.

Concerning the baneful effects of the chronic on the acute insane who are convalescing I cannot express my ideas better than to quote the following from the Lunacy Committee's report:

"The acute are often heard to allude with horror to the condition of their chronic companions, dwelling most painfully upon the imminent probability of soon becoming hopelessly lost to home, friends and society, and of living the remainder of their lives in similar seclusion.

"Like begets like, and as the population of any hospital for the insane is chiefly chronic, the acute or curable being a relatively limited number scattered through the various wards, this enforced evil association must rob society of many a useful and productive citizen by placing him in daily contact with those who mar his chance for recovery.

"Humanity demands that the most enlightened policy be applied to the restoration of the curable insane, which would be materially promoted by separating the chronic from the curable, in distinctive separate institutions."

In the five State Hospitals there are 226 of the criminal class. The Committee thinks the House of Refuge in Philadelphia could be bought and adapted for them. New York State has for years provided a separate asylum for this class of insane. It seems to me the need of such an asylum for our State is so obvious as to need no further discussion.

I think the second proposition has everything to commend it. If all the readers of the MEDICAL AND SURGICAL REPORTER who think as I do and who are interested in the subject would write to their Senators and Representatives at Harrisburg much strength would be given to the Committee's recommendations.

—Incipient putrefaction of meat may be tested with sensitive litmus paper. The acid reaction of meat is changed to alkaline by the putrefactive process.

FOREIGN BODY IN THE EAR FOR NINE YEARS.

BY BYRON F. DAWSON, M. D.,

KEWANNA, IND.

Some time ago, while attending a case of typhoid fever in a rural family, the mother informed me that her son had in his ear a grain of corn which had been lodged there several years. The story seemed so improbable that I told her she was undoubtedly mistaken about the foreign body being still in the ear, and passed the case by without other thought or examination. Some days afterwards the subject was mentioned again, and the mother reasserted that she was sure the corn had never escaped. I then made a cursory examination of the organ and found the auditory canal did contain a foreign body of some kind, and directed that the boy be sent to my office for examination, but as he was quite bashful, it was arranged that he should come ostensibly to bring a report of his sister's case.

He came, and in a very few minutes after beginning I had removed from his right external auditory canal a grain of hackberry popcorn, surrounded by a considerable mass of inspissated cerumen.

The history of the case is as follows: the boy was twelve years of age in November, 1890. The grain of corn was put in his ear by himself some time during the winter in which he was three years of age, and was removed February 21, 1891, having been lodged in the canal something over nine years. During all this time his hearing was greatly impaired, while he was at times entirely deaf in the right ear.

The only instruments required were a head-mirror, ear scoop and dissecting forceps, yet he was required to suffer the annoying presence of this foreign body over nine years, because the physicians to whom he was taken were "not prepared to doctor ears," and made no examinations of the case. One of them, however, recommended the use of sweet oil in the ear, with the assurance that it would cause the grain to "work out."

The grain of corn apparently was of its original size and shape, and notwithstanding the irritation to which its sharp point might be expected to give rise, the lining membrane of the ear appeared perfectly normal, and hearing was found to be unaffected after its removal.

HYDROGEN PEROXIDE IN OTORRHŒA.[1]

BY ARTHUR D. MANSFIELD, M. D.,

ASSISTANT IN THE PRESBYTERIAN EYE, EAR AND THROAT CHARITY HOSPITAL, BALTIMORE, MD., ETC.

By far the greater number of ear complaints are those in which otorrhœa appears as the prominent symptom and as the cause of the patient's being brought for advice and treatment. The diagnosis of otorrhœa is easy enough to make, but the trouble is not always so easy to cure.

The cause of the otorrhœa may, in the vast majority of cases, come from the middle ear, generally being an inflammation set up there by transmission along the Eustachian tubes from the pharynx, and resulting in final perforation of the tympanic membrane and a discharge externally.

Again, the otorrhœa may result from an inflammation of the external meatus alone, when the drum is not involved at all, or, if so, only externally.

The main indication in suppurative inflammation of the ear—no matter whether from the middle or external ear—is cleanliness; and, as it is almost impossible to wash the ear out properly by the ordinary cleansing means, the advent of a substance which will attack pus, and pus *only*, is a decided advance. Such a substance is found in hydrogen peroxide.

I have had very good results from the use of hydrogen peroxide in all otorrhœas, treated both in private practice and at the Hospital. My method is usually to wash out the ear as thoroughly as I can with a warm alkaline solution—generally a solution of sodium bicarbonate, and then, when the ear has been dried with cotton, to instil hydrogen peroxide and allow it to remain in the ear for ten minutes or so. The action of the peroxide is to decompose the organic matter present by oxidizing it, giving up its atom of nascent oxygen which very readily combines with whatever free carbon, sulphur, or other element it may find. This action gives rise to some such remarks as these from the patients: "it causes a bubbling," or "it boils," or "fries." One likened it to soap-suds. The action is to decompose all the pus present and to clean out the external ear much more efficaciously than water and syringe can do.

After using the peroxide, it is well to again syringe out the ear, to wash away any epithelial scales or detritus that may accumulate from the action of the peroxide. The ear is now thoroughly cleansed of all inflammatory products, and the membrane can be inspected easily, and its condition ascertained. It has been my custom to dust the ear with powdered boric acid and to order the peroxide to be used at home twice or thrice daily, as this may be indicated. I usually have the patient recline, with the ear that is to be treated uppermost, and have some one fill the ear with peroxide of hydrogen. The patient is instructed to allow the drops to remain in the ear for ten or fifteen minutes, then the meatus is wiped out with clean cotton as well as possible, and left alone. This is usually done twice a day, but may be done oftener if deemed necessary on account of the quantity or duration of the discharge. The action of the peroxide is not only cleansing, but also disinfectant, as it has a germicidal effect upon the pus-producing organisms.

Seeing the cases day after day, and cases more or less chronic in character, I have been enabled to note gradual recovery in cases where the ear has been discharging for years without cessation.

The time for recovery varies in the different cases, and depends upon many factors, especially upon the zeal and faithfulness with which the physician's instructions are carried out. As a fair average I have found a week or ten days' treatment generally sufficient to cure a case of otorrhœa, no matter how long the ear may have been running. In many of the acute cases, when treatment is applied in its very incipiency, a few days suffice to effect healing of the lesions and stopping of the otorrhœa.

One complication I have noticed, that may be well worth mentioning, is this: persistent rawness and pain in the external meatus, which follows the use of the peroxide in some cases after all otorrhœa has ceased. This is of no consequence whatever, and soon yields to the use of any of the milder astringents, such as boric acid dusted in the ear. Hearing is not by any means restored in all cases; for, if the case be one of long standing, the chances are that the drum is damaged to such an extent that repair seems impossible.

In conclusion, I may say that I think the

[1] Read before the Medical and Surgical Society of Baltimore, March 26, 1891.

use of hydrogen peroxide in otorrhœa supplies a long-felt need and answers the purpose most admirably. It is a drug for the specialist and for the general practitioner. It may be kept on hand and is generally efficacious when needed, or it may be ordered from the druggist when needed, and instilled into the ear by the patient.

Hydrogen peroxide is undergoing now a "boom," and I feel that many of its uses will be forgotten, but that its use in otorrhœa will remain with us.

PERISCOPE.

Treatment of Uterine Tumors with Electricity.

The *University Medical Magazine*, April, 1891, cites Keith as stating in the *British Medical Journal*, Feb. 14, 1891, that the criticisms with which Apostoli's treatment has been so generally received, give him now, after two more years of experience, no concern. He knows some things that it cannot do; he knows better what it can do. Delicacy of manipulation, perseverance, and a knowledge of electricity are essential in carrying out this treatment with any hope of success or improvement to the physician, or comfort to the patient. The results are slow, but comparatively certain. The only quite hopeless cases seem to be fibro-cystic tumors and fibroids in which hydrorrhœa exists to a great degree. In these cases there is improvement up to a certain point, but it is not permanent. No fewer than one-half of the cases of fibroid seen during the last two years were advised to have no treatment whatever.

Keith regrets no part of his past work so much as that in which he removed so many ovaries for small bleeding tumors. During the last three years and a half he has not performed a single hysterectomy in soft or solid fibroids. He has operated three times for large fibro-cystic tumors, one of thirty-eight pounds, one of seventy pounds and another of seventy-six pounds. In two cases only has he removed ovaries for small bleeding tumors. In one case there was an ovary as large as a hen's egg; the other had two small ovarian tumors.

The electrical treatment is tedious, but may be shortened by using high intensities, with puncture. In only one instance has it been necessary to use an anæsthetic. Till quite recently Keith saw few cases of *small* tumors with symptoms so severe as to need treatment; lately many such presented themselves. The following were the seven earliest cases: (1) Small bleeding fibroid: profuse and painful menstruation; cured by electricity. (2) Small uterine fibroid: painful and profuse menstruation; disappearance of tumor under electrical treatment. (3) Fibroid uterus: almost continuous menstruation; electricity; disappearance of growth. (4) Small uterine fibroid: unusual amount of pain, with suspicion of ovarian and tubal disease, and disappearance of tumor under electricity. (5) Fibroid tumor in posterior wall of uterus: profuse menstruation; disappearance of tumor under electricity. (6) Small uterine fibroid, with profuse hemorrhages; enlargement of ovary; disappearance of tumor under electricity. (7) Long-continued bleeding fibroid: cured by electricity. Thus in five of these cases the fibroid entirely disappeared.

After the treatment is stopped, there may in some cases be no apparent benefit, and the good obtained may not be seen for several months. No explanation is given of the principle of the process which causes the absorption or diminution of the enlargements. In these cases it is certainly *not* that of electrolysis. It must be looked for rather in some form of electrical osmosis. Several of the cases had enlargement of the ovary; not only did the fibroid disappear, but also the ovarian enlargement.

This treatment *almost always* relieves pain. It *almost always* brings about diminution of the tumor—sometimes rapidly. It *almost always* stops hemorrhages—sometimes rapidly. The results are *almost always* permanent, and the growth of the tumor, if it be not lessened, is stopped. The general health is immensely improved. By *almost always* he means nineteen cases out of every twenty.

Health Legislation in California and South Carolina.

Henry A. Riley, Esq., says in *The American Practitioner and News*, February 14, 1891: Two curious cases, involving the power of communities to legislate for matters really or falsely alleged to be against public health and morals, come to us from California and South Carolina. The city of San Francisco has, as is well known, a large Chinese

population, which is not looked upon with favor by the rest of the community, and a resolution was enacted some time since by the city authorities requiring all the Chinese either to remove outside the city and county of San Francisco, or else to a certain designated portion distant from their present quarters. This excited great indignation among the Chinese, and the courts were at once appealed to in order to prevent the execution of the ordinance.

The United States Circuit Court decided in very plain and curt language that the ordinance was unjust, unconstitutional and must not be enforced. It said: "The obvious purpose of this order is to forcibly drive out a whole community of twenty odd thousand people, old and young, male and female, citizens of the United States born on the soil and foreigners of the Chinese race, moral and immoral, good, bad and indifferent, and without respect to circumstances or conditions, from a whole section of the city which they have inhabited, and in which they have carried on all kinds of business appropriate to a city, mercantile, manufacturing and otherwise, for more than forty years. Many of them were born there, in their own houses, and are citizens of the United States, entitled to all the rights and privileges under the constitution and laws of the United States that are lawfully enjoyed by any other citizen of the United States." The court in this case did not believe that any "health" or "moral" question was really involved, and nullified the ordinance.

In the South Carolina case the inhabitants of a town near Charleston wished to get the advantage of being considered a health resort, and so passed a resolution forbidding the cultivation of the soil within the corporate limits, except to the extent of one-eighth of an acre for each owner of land, and absolutely forbidding the cultivation of rice on the part of any one. The ordinance permitted the cultivation of flowers, vines, fruit and forest trees without interference. As this ordinance excited opposition, it came up in various courts for consideration, until at last the Supreme Court decided that it was valid and could be enforced. The judges held that the powers of local authorities to legislate for the general health could not be overruled by the courts.

There will be little doubt felt by thinking persons that the California decision was a just one, but many will question the South Carolina one as giving undue power to local authorities over the use and control of private property. There has undoubtedly been a considerable extension in recent years of the police and health powers of town and city corporations, but the limit has apparently been about reached.

Koch's Treatment.

In the *Lancet*, March 21, 1891, Dr. McCall Anderson, Professor of Clinical Medicine in the University of Glasgow, says: The extravagant laudation with which the treatment of tubercular diseases by means of Koch's fluid was ushered in has given place in many quarters to an equally absurd depreciation of its merits. Considerable practical experience of its results having been gained in the hospitals of Glasgow, it is right that we should take stock of our knowledge and compare notes with one another, in the hope that we may arrive at just conclusions. But as our experience is necessarily a short one, it follows that whatever views may be expressed must be taken as provisional, and liable to modification when a large number of cases has been dealt with, and when they have been under observation for a longer period of time. Before bringing any cases under notice, it may be well to indicate, in a general way, some of the conclusions which, I think, may be derived from them. When a patient is inoculated for the first time with an appropriate dose of the fluid, there result in typical cases—(1) elevation in temperature, (2) a series of other constitutional symptoms, and (3) local reaction. But, in a considerable number of instances, one or more of these sets of symptoms may be absent, or only present in a minor degree. Thus it is not uncommon to find decided reaction at the diseased part with little, if any, constitutional reaction and fever. Or there may be an absence of fever, but other well-marked constitutional symptoms; or local reaction may be alone observed. But, as a rule, the more pronounced the fever and other general symptoms the more decided is the local reaction, and *vice versa*.

With regard to the body heat, the first effect of the inoculation in many cases is to produce a temporary lowering of the temperature, but this soon gives place to a rise, which reaches its maximum generally within twelve hours—sometimes not until the following day; or there may be a primary rise

of temperature the day after the inoculation, and a secondary one the following day, which may even be greater than the first. First inoculations are likely to lead to a slower rise and one of longer duration than subsequent ones, in which the tendency is towards a rapid rise and an equally rapid fall of temperature. It is not, in my opinion, desirable to encourage an elevation which exceeds 104° F., and in this connection it must be borne in mind that an inoculation frequently produces a greater rise than the preceding one, although the dose is not increased. The other constitutional symptoms observed varied in different cases, but the most common were chilliness or rigors, headache, pains in the back and throughout the body, sickness, vomiting and prostration. In two cases what has been described as a measly, but which is really a roseolous, rash made its appearance, but in no instance was a scarlatiniform eruption induced. As regards the local reaction, we can best observe it when the lesion is on the surface, although the symptoms arising when internal organs —such as the lungs—are affected, leave little room for doubt that similar changes take place in them. The first result—in a case of lupus, for example—is the occurrence of redness and swelling which are not limited to the affected part, but spread to the skin in the vicinity, which often assumes an erysipelatoid appearance, and a serous exudation takes place from the diseased surface which dries into crusts. Each succeeding inoculation is followed by less inflammation, and when serum ceases to exude, the crusts become very dry, contract, and finally fall off, leaving a dry, scaly, rosy surface, the cicatrix being smooth, and less pronounced than after any other local treatment with which I am acquainted. When any isolated lupus nodules lie imbeded in cicatricial tissue, the inoculations may fail to destroy them, the poison being apparently unable to get at them ; and what may be done under these circumstances is to penetrate them with a pointed stick of caustic, and then to inoculate again, when a certain amount of reaction ensues, generally making short work of them.

From what I have said it may be inferred that, when the lupus nodules are confluent, the result is better than when they are discrete, and the best cases of all are those in which the whole patch is in a state of ulceration ; that is to say, the worse the case the more brilliant is likely to be the result. But, while tuberculin is often in a position entirely to destroy the existing disease, it seems to have little influence in the way of preventing relapses, which must be warded off by endeavoring to improve the general health, especially by giving anti-strumous remedies—above all, cod-liver oil—just as we have been in the habit of doing formerly in connection with the use of local applications. A patient who cannot take cod-liver oil in full doses—say, to the extent of 3 oz. daily—has a poor chance of being permanently cured. As regards phthisis, the time is much too short to entitle one to formulate very positive conclusions, but I am quite sure that it is undesirable to treat advanced cases in this way. Indeed, I have no doubt that such treatment is dangerous ; or, at any rate, it is very apt to leave the patient in a worse plight than before. But there is equally little doubt if we get a case at the very commencement, before excavation, with a very limited amount of lung tissue involved and the general health not being undermined, the best results may often be obtained. In considering the propriety of carrying out this treatment in a given case of phthisis it must never be forgotten that the extent of the disease is almost invariably considerably greater than the physical signs would seem to imply. Indeed, in most of the patients treated, moist râles, with or without evidences of consolidation, have made their appearance at parts where, previous to the commencement of the inoculations, there were no traces of pulmonary mischief. These new physical signs cannot certainly *always* be attributed to the development of new centres of disease, the result of setting free tubercle bacilli to work mischief elsewhere, because they sometimes appear immediately after the first inoculation.

With regard to diagnosis, there can be no doubt that Koch's discovery is a most valuable one, because, although it cannot be asserted that the fluid exclusively attacks tuberculous tissue, it is *certain* to inflame parts which *are* tuberculous when the appropriate dose is reached, and it undoubtedly often ferrets out quite unsuspected foci of disease.

As to the dose, I think it may be laid down as a good rule that not more than one or two cubic millimeters of the 1 in 100 dilution should be given as a first injection, especially if internal organs are involved, or if the patient is weakly ; but the appropriate dose varies in different persons, just as we

find in connection with the administration of medicinal substances. It is much better to start with a dose which may fail to yield any result than with a large one which produces violent local and constitutional reaction, it being always safer to feel one's way at the outset. We are all cognizant of the fact that the system soon becomes habituated to the use of certain drugs, so that after a while doses may be taken with impunity which might have poisoned the patient at the outset. And there can be no doubt, with reference to tuberculin, that a remarkable tolerance is speedily established; so much so, that we can often ultimately give an inoculation without any result one hundred times stronger than that which at first produced well-marked local and general reaction.

When I commenced to inoculate patients I made use of the syringes recommended by Koch, and with which we are all familiar; but I found that they were somewhat troublesome and uncertain in their manipulation, especially when not manufactured with the greatest care. So that most of my inoculations have been made with an ordinary subcutaneous syringe, graduated for the purpose, which has none of the drawbacks of the other, and from the use of which I have experienced no inconvenience, while inflammation at the seat of puncture has never occurred.

In conclusion, I may be permitted to say this much, at least, with regard to tuberculin, that, whatever the ultimate verdict of the profession may be with regard to the scope of its utility in diagnosis and treatment, it is possessed of most remarkable and unique properties; and no one who has had much practical experience of it, can grudge the encomiums and the honors which have been showered upon its discoverer.

Dr. Anderson concluded by showing a series of cases upon the treatment of which the above remarks were based.

Menstruating Nurses.

That excellent journal called *The Nightingale* discusses in its issue for March 28, 1891, the question whether or not menstruation should be regarded as disqualifying a woman for surgical nursing. Our contemporary says: "About two years ago we referred to what was then to us a novel suggestion. This suggestion came from a Chicago surgeon and was to the effect that the menstrual discharge rendered the nurse infective and unfitted her for service in an obstetrical case, that a menstruating nurse, in other words, should be excluded from such service. Still more recently a surgeon in one of our New York colleges has in the presence of a large class substantiated this inference. This surgeon says that he regards the menstruating nurse as a source of infection and announces as an 'unwritten law' of his practice the exclusion of menstruating nurses from all major operations. Now, if enforced, this rule will be a serious matter to the surgical nurse as it will mean incapacity for three months out of the twelve—it will mean even more than that—it will mean total incapacity from the impossibility of arranging cases so as to accommodate her physiological functions. If this rule be enforced, we say, all women nurses will be driven from the field of surgical and obstetrical nursing. Even in the hospital we are told that it will be impossible to cover its requirements, that in spite of the large classes in our training schools there will come times when not a single nurse will be available. We are told that the pupils of the training schools cannot be depended upon to arrange themselves in single file and to so distribute their incapacities over the month; but that these incapacities will be apt to occur in groups, that a large group of nurses will be found menstruating at one and the same time. Unless women then are to be replaced by men, in surgical and obstetrical nursing, this 'unwritten law' must be inoperative.

"But let us consider the ground of its adoption. We acknowledge that the vagina contains bacteria, we acknowledge that the menstrual blood is already partly disintegrated and that it rapidly becomes offensive. The same, however, is true of the perspiration and other excretions. It would be as rational to exclude every perspiring man from the operating room as to exclude every menstruating woman. The cases are parallel. Again, if curetting and other operations can be performed during menstruation with safety this fact proves the original innocuousness of the menstrual discharge."

Upon this point Dr. William Goodell's opinions about menstruation which were cited in an editorial in the REPORTER, February 28, 1891, are quoted, and a letter from Mr. Lawson Tait is published, in which he says: "The question of dealing with menstruating women in relation to my op-

erations has never entered my mind for a moment. It is a suggestion that has never been made to me till the present moment and I cannot imagine anything more ridiculous. For years and years of my work, in every case the anæsthetic was given by a woman. There are always four or five nurses about in each operation, and I dare say that very few of my operations indeed are performed without some of the female persons present being in that condition."

Treatment of Headache.

Dr. Dercum, in a lecture published in the *University Medical Magazinè*, April, 1891, speaks as follows in regard to the treatment of headache.

We come now to the treatment. This is an exceedingly knotty question. I shall not spend time in the consideration of the treatment of organic headache. I can indicate only general principles. If there is a tumor, it should be removed if possible. If there is meningitis, it is to be dealt with on general principles. If the patient bears the iodides and mercurials well, they should be given, while at the same time counter-irritation should be practiced. Especially is this treatment applicable in headache following sunstroke.

A great deal might be said in regard to the treatment of the cases that belong to the group of migraine. In the first place, the patient should be put on such constitutional treatment as will improve the general condition and bring it up to a high standard. Every error of diet should be eliminated, not because the patient has gastric catarrh, but because he suffers with migraine. These patients should be given large amounts of milk in addition to other food. The food given should be in a digestible form. Exercise is another important factor. This should be rigidly insisted upon. However, in spite of what you do, although the attacks may be less frequent, it is improbable that you will be able to stop them altogether. I do not say that this is invariably true, but it is so in many cases. In addition, it is necessary to practice some decided interference at the time of the attack. One plan is to use morphia. Of course, that is a decided way of dealing with pain due to any cause. This is, of course, a dangerous method of dealing with pain, especially where there are recurring attacks, for the patient inevitably acquires the morphia habit. Again, especially where the migraine is associated with sympathetic spasm, the pain is often relieved by large doses of whiskey, especially if it be given hot. Various drugs have in recent times been given, not only for migraine, but also for other head pains, notably antipyrin and antifebrin. Antipyrin is a very valuable drug, and is a decided addition to our armamentarium. In some way or other the notion has got abroad, and is held by many people, that antipyrin is a dangerous drug. An ordinary individual will stand ten, fifteen and even twenty grains without noticeable effect on the heart or pulse. Antifebrin is a dangerous drug, and should not be given in large doses. Antipyrin, however, only exceptionally acts as a depressant. A good plan is to associate the antipyrin with bromides. The depressing effect, if any, can be prevented by giving digitalis, or especially aromatic spirits of ammonia, which is acceptable to the stomach in this condition. Cannabis indica also enjoys a reputation in the treatment of migraine, and a just one. One-fourth to one-half a grain of the extract may be given at intervals of four hours.

In the treatment of functional headaches, due to anemia or chlorosis or to hyperemic states, general principles, of course, must guide you. The anemic patient needs the best hygiene, and especially does he need iron. He requires the most nutritious diet. The headache of chronic nervous exhaustion and neurasthenia may also be spoken of here. The only way in these cases is to put the patient to bed for a while. Forced feeding, especially with milk, and massage and faradization, will cause improvement in the general health, and the headache will disappear. You may treat some of these cases in other ways, but you will make no impression on the headache until you put them to bed. If you make the diagnosis that the headache is due to neurasthenia, do not hesitate to tell the patient of the necessity for rest, else you will fail in relieving the headache, and your reputation will suffer.

The headaches due to disorders of nutrition, as the various diathetic headaches, will call for their special treatment. The uremic, rheumatic and diabetic headaches suggest what is to be done. The same is true of the toxic headaches. I shall here refer to one point only, and that is in connection with the malarial headache. This is not, as a rule, relieved by ordinary doses of quinine, such as would prevent the recurrence of a chill. If you do not give large doses, you will fail.

Twenty and even thirty grains are required to make an impression. Where it is necessary to give very large doses, it is well, in order to avoid irritation of the stomach, to give the drug in ten-grain doses in capsules every hour with a quantity of milk, until the required amount is taken. In that way the quinine will dissolve slowly in the presence of the curds of the milk, and there will not be much irritation of the stomach. In order to obtain the best effect the remedy should be administered four or five hours before the expected attack.

In regard to headaches of reflex origin, each case will require the appropriate treatment. The eye, nasal and gastric headaches suggest their respective treatment. Gastric headaches are due to chronic gastritis, and the treatment should be directed to the relief of this condition. Do not let yourself be turned aside from the proper thing to do by dabbling with pepsin and other digestants. Put the patient on a bland diet, give him nothing but milk, perhaps with a few crackers, or stale bread. To this possibly may be added beef juice from time to time. If he will consent to give the stomach a rest he will recover. This is the most important part of the treatment. Nitrate of silver is also of service. One-fourth of a grain of nitrate of silver, with hyoscyamus or belladonna, may be given thirty minutes or an hour before meals. It should be swallowed with as small a quantity of water as possible. Even if there be formed, as some assert, an albuminate of silver, there can be no doubt that the drug has some alterative effect upon the stomach. It probably acts as a stimulant and a sedative. It is probable that it rapidly undergoes chemical change, but we know that cases improve more rapidly with silver than without it. During the attack of headache it is well to give an emetic, and preferably one that will not irritate the stomach. You would not, under these circumstances, think of giving mustard. You could give the patient warm water until he could retain no more. The moment vomiting takes place the headache is relieved. The vomiting should be followed by the administration of an alkali, such as bicarbonate of soda, soda-mint or a tablespoonful or two of lime water in ordinary water.

If you have an obscure headache, for which you can find no obvious cause, and you detect physical signs of cardiac disease, you must take this into account. Do not forget, further, the part that the bowel may play in the production of headache. Uterine headaches will require their special treatment.

Regulation of Prostitution.

The *Medical Record*, March 28, 1891, says editorially: The discussion of the subject of licensing prostitutes and regulating prostitution has again become a subject of present interest. The Legislature of Missouri has before it a bill providing for the regulation of prostitution. At the International Medical Congress, Dr. Thiry read a paper on the subject which excited much discussion, and quite recently it has been brought up before the New York Academy of Medicine. We notice also that even in so remote a land as Japan there has been an agitation started, and the Imperial Diet has been memorialized by a large number of citizens, who ask for the abolition of the license system and present statistics showing that it is a failure in Japan.

Those who assert that the licensing system should be established, produce statistics which show that it reduces the amount of venereal disease. For example, in France, M. Commenge has recently stated, at a meeting of the Academy of Medicine of Paris, that he had collected the statistics of the number of diseased prostitutes found in the decade from 1878 to 1887: First, among women registered by houses or cards; second, among those women who—though registered—were the object of more or less frequent arrests, and constituted a special class under the name of *femmes du dépôt;* third, and lastly, among the uninspected, or women that lived by clandestine prostitution. The results obtained, based on nearly a million visits, showed the number of cases of syphilis in each thousand examined to be respectively 3.1, 2.7 and 23.9. Of other venereal diseases 3.0, 2.5 and 14.5.

Thiry, of Brussels, gives similar figures. The Vienna syphilographers are all naturally in favor of regulation. Neumann would have prostitution entirely under government control. Prostitutes should, according to him, be regularly examined, and, if diseased, quarantined. Soldiers, sailors and even factory hands and wet nurses should also be regularly examined. Already in Vienna each prostitute receives a book containing a description and photograph of herself, and a copy of the laws relating to prostitution.

No one under sixteen can be registered, no persons afflicted with organic or constitutional disease. Sanitary examinations are made twice a week, all diseased women are put into hospitals, primary syphilitic cases are quarantined for three months, and kept under treatment for two years. Clandestine prostitutes are treated in the same way by their own physicians.

The results of this treatment in Vienna are not dwelt upon with so much enthusiasm as the methods. Vienna is rank with venereal disease. The idea that continence is a moral virtue, simply does not exist for men or for lower-class women, half the births in the city are illegitimate, and Austria's Crown Prince shoots himself as the result of a low intrigue. Statistics are brought forward by the opponents of licensing which appear to show that the system is a failure in Paris, Berlin, Italy and Great Britain. The statement of Lacour, chief of the police of Paris, that licensing does not protect and that prostitution cannot be made safe, is also often quoted.

It seems, therefore, that judgment must be formed upon general principles, since the facts are so inadequate. One general principle, viz., that the sexual propensity cannot be regulated by law, seems to be a pretty safe one. If there is a general desire in a given community to do a thing, it will be done. Regulating prostitution, however, is said to make this indulgence safer. Facts do not quite prove it. Furthermore, it is admitted that all attempts to register and examine prostitutes thoroughly have failed. And for our part we should dislike to feel that members of our calling would accept so low and despicable a position as that of government examiners of prostitutes.

A mistake which advocates of the licensing system make is that of considering the question solely as a sanitary one. Even if it were proved that syphilis were reduced five per cent. in a given community, it would not prove that the community was a happier or healthier one. For under the stimulus of a government assurance that prostitution was safe, the amount of illicit indulgence might be doubled, with the result of increased domestic trouble and moral degradation. The injustice of forcing women to be examined, and not men, has often been referred to. M. Thiry considers this a "fallacious idea," though upon exactly what grounds he fails to state.

It has seemed to us, taking all the facts into consideration, that the safest method of treating the subject of prostitution is the educational one. Its moral and physical dangers should be assiduously inculcated, especially upon the rising generations.

Rupture of Linea Alba.

In the *Australasian Medical Gazette*, January, 1891, Dr. R. D. Pinnock, of Victoria, writes: When reading Dr. Monsell's interesting case of this rare accident it occurred to me that Dr. Dimock, one of the oldest and most respected members of the profession in this city, had, some time ago, told me of a similar experience in his own practice. I have, therefore, reminded him of our conversation, and he has kindly allowed me to send you the following particulars which he has looked up from his notes and which, he informs me, have never been previously published:

"Mrs. Sharwood, a wheelwright's wife, aged (at time of birth of fourth child) 35 years; confined on November 5, 1876. During labor linea alba ruptured, and the limbs of the child could be distinctly made out through abdomen. The late Dr. Nicholson also saw this case and recognized the nature of the accident. The labor terminated safely with a living child, but she was very ill for 17 days afterwards. Three years afterwards she had another child and a good time, and she is still living, but at a distance from Ballarat."

Dr. Dimock has been nearly 40 years in active practice, and has had an immense midwifery experience, but never saw or heard of a similar case until I mentioned to him the one published by Dr. Monsell. He also tells me of another unusual experience he had in midwifery, which is well worth recording.

The labor was going on quite normally in every way, and when the head of the child was actually *visible* outside the vulva it suddenly retracted, labor pains ceased, and on examination he found the child had returned within the uterus, and there was no return of labor for 38 hours afterwards, when the birth took place easily and naturally.

During last year I was consulted by a young man in charge of a country railway station for severe pains in the abdomen. He said he had overstrained himself in helping to push some empty trucks the day previously. On examination I found the linea alba ruptured for a space of three

inches immediately above the umbilicus, and the contents of the abdomen easily felt between the separated recti. Pressure inwards at this point caused a sickening pain. Lateral pressure approximating the recti gave great relief. I strapped the abdomen firmly and ordered him to go to bed and lie on his back for a week, but never saw anything of him again. This case was seen with me by Dr. Whitcombe, who agreed in the diagnosis.

I do not recollect any similar case being reported, and therefore mention it in connection with the other.

Trichloracetic Acid as a Test for Albumin in the Urine.

Dr. Nestor Tirard, Senior Assistant Physician to King's College Hospital, London, writes to the *Lancet*, March 21, 1891:

"The practical value of trichloracetic acid as a test for albumin in the urine is so great that any sources of error in its employment should be carefully noted. In a letter from Dr. C. F. Heywood, of New York, which appears in the February number of *Merck's Bulletin*, the writer, after speaking in very laudatory terms of the value of the test, says: 'I have yet to find that it declares any *other elements* of suspected urine than albumin,' and he recommends that a saturated solution should be carried about in the pocket. I have long been employing this test, both in private and in insurance examinations, and can speak very highly of its results. I have been in the habit of comparing its reactions with those given by nitric acid and picric acid, and while I have never found it fail to react in specimens in which albumin has been discovered by other tests, it has given a line of opacity in numerous samples which have been unaffected by nitric acid or picric acid. In some of these the trichloracetic acid appeared to be a more delicate test, since in cases with a history of an acute attack of nephritis the urine has often given a line of opacity after it might have been declared free from albumin when the customary tests were employed. On the other hand, the need of the warning originally given by Boymond has been very strongly impressed upon me by several cases—viz., that when the urine is rich in urates the reaction may appear without any albumin being present, and this possible source of error can only be avoided by free dilution of the urine before making the test.

"With regard to the desirability of carrying this reagent in the pocket, the effects of a crystal on a piece of blue paper or on the blade of a knife have been sufficient to deter me from making the experiment. Although trichloracetic acid may be used either in a solid or liquid form, it gives the most striking results when a good-sized crystal is dropped into the test-tube containing the urine. The crystal speedily liquefies, and, if albumin is present, produces a zone of turbidity in the urine just above it, otherwise a sharply-defined line marks the junction of the white acid with the yellow urine. The zone of turbidity appears immediately when due to albumin, but when due to urates it forms more slowly, and is not so wide."

Angina Pectoris.

The *Medical Press*, March 18, 1891, says, editorially:

Angina pectoris is by no means what may be termed a new disease, yet its phenomena and its very nature still present so many obscurities that the subject has monopolized the almost unprecedented number of three evenings' discussion at the Medical Society of London. Those who take their medicine and pathology from text-books will be saddened at finding the divergence of opinion on the part of authorities with respect to the precise nature of the morbid process which gives rise to symptoms designated in their integrity under the name of angina. It is but too obvious that under this somewhat misleading title are grouped conditions of widely different origin, of very different nature, and amenable to vastly different treatment. This must infallibly prove to be the case when nomenclature is based on symptoms rather than on pathological observation, and it justifies the attitude of those who evinced a desire to dispense with the use of a term which implies nothing except pain and distress in a particular region of the body. The term angina pectoris is about as scientifically precise as stomach ache. Anginal attacks vary immensely, as is well known, both in severity and in import, but all attempts to group them on a more scientific and topical plan have proved unsatisfactory. The most surprising feature of the prolonged but instructive debate was the antagonism of views respecting clinical

details which one would have supposed would have been by this time clearly made out. For instance, is angina, in its principal variety, a disease associated with high arterial pressure or not? At first sight the evidence in favor of the pain, which is the most salient symptom, being due to overdistention of the heart, appears to be overwhelming, and this view is reinforced by the palliative effects of drugs which lower arterial tension, such, for example, as the nitrites, the use of which in medicine is one of the most striking examples of the application of physiological investigation to practical therapeutics. There is, on the other hand, evidence which we cannot afford to overlook that heightened blood pressure is not an invariable or even an essential concomitant of angina, while in many diseases associated with an abnormally high blood pressure, anginal symptoms are comparatively rare. As to the neurotic hypotheses according to which angina is referable to an unproved and unprovable neurosis of the heart, these may for the present be dismissed with the Scotch verdict of "not proven." It is worthy of remark that most cases of angina occur in persons not constrained to hard work, though the first attack is frequently associated with, and dates from, some unusual muscular exertion calculated to throw an unwonted strain upon a heart which has been enfeebled by senile or other degenerative or organic structural changes. It is, moreover, distinctly associated with the gouty diathesis, and there is much to be said in favor of the view that what we call angina pectoris is in many instances only the manifestation of a gouty heart. This is not inconsistent with the view that it may be directly the result of overstrain of the heart, for it is not unreasonable to infer that the proclivity which gout shows to attack damaged tissues generally holds good in respect of the heart just as in the case of joints, etc. Then, again, as was clearly pointed out by Dr. de Havilland Hall, a certain proportion of cases which are diagnosticated to be anginal really belong to quite another category, and several instances are on record in which the pain and distress which were supposed to be pathogenic of angina have subsequently been shown to be due to hepatic colic, indeed, the resemblance is occasionally so close that it may be well-nigh impossible to distinguish one from the other unless suspicion be aroused as to the veritable nature of the mischief. The observations and inquiries which can alone elucidate the moot points in this protean malady are unfortunately of a kind not readily accessible to the ordinary practitioner, but it ought not to be difficult for those whose means of investigation are more extensive to provide us with accurate and reliable data to go upon. At present there is too much surmise, and too little direct observation, and this accounts for the difference of opinion which the discussion has elicited on matters of fact.

The Fluviograph.

The *Engineering Record*, March 28, 1891, says: At a recent meeting of the Société d'Encouragement, Mr. Ch. Mocquery, Chief Engineer of Bridges and Roads, described what he termed an electric "fluviograph," an instrument designed to register at any desired distance, by means of electricity, variations in the height of water level of a water-course, and to give timely warning at sites of dams of impending floods, so as to enable adequate means to be taken to provide for heavy rushes of water.

Briefly described, the device consists of a float about 1 inch in diameter, which rises and falls in a vertical cast-iron tube, the latter being in direct communication with the river whose varying levels are to be recorded. This float transmits its motion to a wheel, whose circumference measures exactly one meter (3.28 feet), and which gears with another wheel of such proportions that every five centimeters of vertical displacement of the float corresponds to an interval of two teeth on the smaller wheel. A conveniently arranged electric contact thus permits of sending an electric current through a wire at every such displacement, and gives indications of the nature of the variation in the water level. These can be recorded on a chart. Arrangements can also be made for electrically sounding a high water alarm. The device is said to have been in use on the river Seine since 1882.

—Stern, of Breslau, says that bacteria sink to the floor within two hours, in a room perfectly quiet; and recommends that rooms vacated by patients be closed for twenty-four hours, after which the furniture should be carefully removed and the floor and walls washed with sublimate solution.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

SPERMINE.

The craze over Brown-Séquard's so-called elixir led to attempts to find an ingredient in the semen or testicles which would produce the effects claimed for the testicle-juice he used. Such a substance has been quite largely advertised by an enterprising firm of manufacturing chemists in Detroit, under the name of "Spermine." This material, however, is not new. Spermine, as the *Chemist and Druggist*, November 1, 1890, says, has been known under various names since 1851: as Charcot or Charcot-Neumann crystals, as the asthma crystals of Leyden, and as Schreiner's crystals. In 1865, Boettcher found them in semen, and they have been obtained from the spleen, the blood, the spinal cord, the white of egg, sputum and old anatomical preparations. In 1888, Ladenburg and Abel established their identity with ethylenimine ($CH_2.NH$.). The alkaloid, properly called piper-azidine hydrochloride, resembles other ptomaines chemically, and when free has the odor of fresh semen, the same odor sometimes found in sputum being no doubt also due to its presence.

On this subject, *Merck's Bulletin*, February, 1891, states that spermine has not been shown to be identical with piper-azidine, and that it is as yet not obtainable by synthesis. Natural spermine has not yet been obtained pure in any considerable quantity, and the difficulties so far found in the way of its isolation have led to attempts at preparing its equivalent synthetically; but hitherto these attempts have not yet led to any definite result.

On a survey of the chemical results published up to the present day, it appears that the synthetic products variously designated as piper-azine, piper-azidine, ethylene-imine and di-ethylene-di-amine are mutually identical; but that their identity with Schreiner's natural spermine from spermatic fluid is not yet established. Ladenburg, who first intimated the possibility of his ethylene-imine being identical with spermine, has taken up this question anew, and is now engaged in a comparative investigation of the two substances. According to Bock, the excitant properties ascribed to natural spermine are totally absent from the synthetic compound above named.

From all this it will appear that chemists and manufacturers of pharmaceutical preparations feel quite a lively interest in this substance, which appeals so strongly to the imagination, and that their efforts have been more barren of results than have been those of the experimenting clinicians of Europe—we say Europe, because the folly was soon over in this country. In Europe, we find Brown-Séquard from time to time reporting brilliant results from the employment of testicle therapy, and once in awhile some one else produces seemingly corroborative evidence to its worth. In Russia, we are told, Dr. Roschtinin reported, in March,

1890, a series of experiments which he had made with the injection of spermine, and declared it had proved an excellent stimulant in asthma with heart complications, paralysis of the extremities, angina pectoris, diabetes, fatty degeneration of the heart, and in pneumonia. It is said also that spermine has been used with good results by other Russian physicians in delirium tremens, tuberculosis, and atonic ulcers of the leg.

If it could really do all this it would be but little inferior as a remedy to some things which are advertised in the newspapers; but after reflecting on the subject, we incline to the opinion that spermine is an agent better suited to the use of persons of an imaginative turn of mind and sanguine disposition than to that of calm and critical practitioners. Its temporary acceptance seems to be only one of the evidences we have recently seen that the medical profession may occasionally try to take its bearings from a meteor instead of from a star.

TREATMENT OF CHRONIC CONSTIPATION WITH BORIC ACID.

Chronic constipation may be the result of stricture of the bowel, or of chronic catarrh, or be caused by the pressure of some organ, such as an enlarged or retroverted womb, which occludes the lumen of the bowel. But there are a large number of cases of chronic constipation not to be referred to any organic or mechanical cause. In many cases the bowel is in a sluggish, insensitive, atonic condition, which is due primarily to neglect on the part of the patient to heed the first gentle warnings that the bowel needs to be emptied. As this neglect becomes a habit, the bowel itself gradually ceases to make its condition manifest, and chronic constipation develops. The symptoms and distressing consequences of the condition are well known to every physician, and they need not be mentioned in this connection.

In recent years there has been a tendency to use purgatives as little as possible, and to resort to massage, electricity, gymnastics and baths. These methods can be carried out when the patient has a skilled attendant and sufficient means and leisure.

In many cases, glycerine by the bowel is to be preferred to the administration of purgatives by the mouth, and its use necessitates less loss of time and less change in the patient's habits of life than when massage, electricity, etc., are used. A more recent remedy than glycerine is suggested by Dr. Flatau, in the *Berliner Klinische Wochenschrift*, March 2, 1891. Flatau recommends powdered boric acid very highly in those cases in which, as the result of chronic inflammation of the rectum, there is sluggishness of the rectal mucous membrane, a circular border projecting more or less at the point where the rectal mucous membrane merges into the anus. In such cases, the buttock upon one side is strongly abducted, the parts are carefully washed with cold water and then dried, and finely-powdered boric acid is applied to the exposed rectal mucous membrane. The quantity used by Dr. Flatau is rather indefinitely expressed as a "good knife-point full," and he uses it either by dusting it on the part or by pressing it upon the part and then rubbing it in. In the cases in which there is torpor of the colon, the boric acid must be used by insufflation.

At first, in the rectal cases, the treatment should be carried out by the physician, but later it may be entrusted to the patient. Insufflation, however, must be done by the physician. For this purpose, a short tube of pretty large bore is inserted into the rectum, and about forty-five grains of boric acid is insufflated by means of a powder-blower. In addition to the cold-water bathing of the anal region before the application, Flatau has the patient rest for a short time after the application of boric acid, in order that the latter may keep its place for a few minutes. In from one-half to three hours or longer, after the application, pretty strong peristaltic movements are set up in the large intestine,

and probably the small intestine takes part in them also. As the result of the increased peristalsis, the feces are pressed down into the lower section of the intestine and so are cast out. The stools are rarely watery.

Flatau says he has not failed to secure good results from the boric acid treatment in any of the cases in which he has used it, provided that it was used in suitable cases. He has used it in about forty cases. The most interesting statement of all, is the assertion that the bowel seemed to grow stronger as a result of the use of the boric acid, and that a normal condition of muscular activity of the large bowel was brought about. Three illustrative cases are reported in full.

Such a simple and harmless method of treating ordinary chronic constipation as Flatau has described, can be carried out by any physician, and the results may be as gratifying as those obtained by the use of glycerine in more acute cases. One need not dwell upon what a boon a simple but effective treatment of chronic constipation would prove to be to many who now seem doomed to swallow some purgative two or three times every week. We hope that the boric acid treatment may obviate this, in a measure, at least; and as each of our readers can try it for himself, it should not be long before we shall know definitely its value in chronic constipation. It is for this purpose that we have called attention to it in the REPORTER.

PHILADELPHIA POLYCLINIC.

The handsome new building of the Philadelphia Polyclinic was formally opened April 2, 1891, with ceremonies which were interesting to those who took part in them, and must have been especially gratifying to the members of the Board of Trustees and Faculty of this institution, who have labored so indefatigably to accomplish the result which they now have attained. The Polyclinic has now what is believed to be the finest building in use by any such institution in the United States. It is admirably adapted for the purposes for which it is intended, and is especially valuable as affording unusually good opportunities to medical men for the close observation of medical and surgical cases. It is an objection to some of the most prosperous Polyclinics in this country, that it is almost impossible for medical men attending them to get much better views of operations or closer investigations of individual patients than is now attainable in first-class undergraduate medical schools, with well-supplied clinics. The Philadelphia Polyclinic affords peculiar advantages in enabling those in attendance to come very close to everything which is done, and in many cases themselves to take part in the treatment, as well as in the examination of patients.

It is pleasant to note that the exercises on April 2 indicated that the Philadelphia Polyclinic has the hearty sympathy and goodwill of the undergraduate medical schools of this city. With its new building in full operation, and its well-known Faculty, it is reasonable to expect that it will now rapidly increase in prosperity and usefulness.

Medical men living within convenient reach of Philadelphia, would at any time find it to their advantage to take a holiday, and to spend it here, where, with the Polyclinic and the active Medical Societies of this city, and the professional atmosphere for which it has a widespread reputation, they could not fail to find advantage and pleasure.

TRAINING SCHOOL FOR DEAF INFANTS.

It has been demonstrated that deaf children can be taught speech and lip reading, be educated and be enabled to communicate with their families and friends through the same, and a number of pure oral schools for such instruction are in existence in the United States. To the complete success of the method, however, it is necessary that these deaf children should be guided and

trained to speech from the age when hearing children begin to learn to talk.

As the majority of these children are poor, and as all mothers, even of those who are not poor, do not understand how to train them to speech, Miss Fuller, Principal of the Horace Mann Day School for the Deaf (pure oral), Boston, established, two years ago, a Home for the training in speech of deaf children before they are of school age. The necessary funds for commencing the good work in New England were raised by the mother of a successfully trained deaf child. The children are, of course, under the care of persons specially trained for that purpose, and their progress already gives great encouragement.

It is proposed to establish in the Middle States, as speedily as possible, such a Home as Miss Fuller has established in New England, and the public are earnestly requested to contribute to the Endowment Fund required for the same. The School will be under the management of Miss Emma Garrett, long known for her skilful and devoted labor for the deaf, and more recently as Principal of the Pennsylvania Oral School for the Deaf, which position she has resigned, to take up this new work.

Physicians probably understand the need for such institutions as well as any class in the community, and we feel sure that the readers of the REPORTER—many of whom are familiar with the work already done for the deaf by Miss Garrett—will approve and support the proposed Home, which will begin the work of ameliorating the condition of these unfortunates at the most favorable time.

RESIGNATION OF DR. DA COSTA.

The Alumni and friends of the Jefferson Medical College will receive with regret the announcement that Dr. Da Costa has resigned from the Chair of Practice of Medicine in that institution. The reason for his resignation, is that Dr. Da Costa desires to withdraw from the cares and burdens of the professorial position in order to have more leisure for his large practice. For twenty-seven years, in one capacity or another, Dr. Da Costa has been identified with the Jefferson Medical College, and it is not too much to say that its present exalted position is in a large measure due to the admirable manner in which he fulfilled the duties of his position, and to the lustre of his reputation, which has so effectively supplemented that of Meigs, Gross, Pancoast and others, whose students respected and loved them, and who were justly esteemed and honored by the members of our profession all over the world.

FAREWELL OF THE EDITOR.

On April 30, 1887, Dr. N. A. Randolph and I leased the publication business of the MEDICAL AND SURGICAL REPORTER for a period of ten years, with the right to terminate the contract—at our option—at the end of any current year. Dr. Randolph lost his life in August, 1887, and since then the whole work of editing and publishing has devolved upon me. Now, in accordance with the provisions of the contract mentioned above, I have decided to give up this work on May 1, and I must therefore take leave, as Editor, of those to whom, for nearly four years, I have spoken every week through these columns.

During this time it has been my desire and endeavor to conduct the REPORTER so as to advance the interests of its readers and to support the honor and dignity of the medical profession. More than once I have acknowledged recognized errors of judgment, and others unrecognized have no doubt occurred ; but I trust that, while under my control, it has helped those who read it, has supported no unworthy cause and has opposed no good one. I have felt, while Editor of the REPORTER, a very warm interest in the welfare of those thousands of its readers whom I have never known personally, and especially in that of those who live far from large centres of population.

For the faithful and laborious practitioners in the country, I have acquired a respect and regard which has increased with each year of my connection with this journal.

To all—in city, town and country—and to my editorial colleagues throughout the land, from whom I have always received courteous treatment, as Editor of the REPORTER, I now say, Farewell.

CHARLES W. DULLES.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

TWELVE LECTURES ON THE STRUCTURE OF THE CENTRAL NERVOUS SYSTEM, FOR PHYSICIANS AND STUDENTS. By DR. LUDWIG EDINGER, Frankfort-on-the-Main. Second Edition. With 133 illustrations. Translated by Willis Hall Vittum, M. D., St. Paul, Minn. Edited by C. Eugene Riggs, A. M., M. D., Professor of Mental and Nervous Diseases, University of Minnesota, etc. 8vo, pp. xii, 230. Philadelphia and London: F. A. Davis, 1890. Price, $1.75.

An idea of the scope of this book can best be given by mentioning the subjects of the twelve lectures which form it. These subjects are: A review of the history and methods of investigating the central nervous system; embryology and comparative anatomy of the brain; the general conformation and histology of the brain; the convolutions and fissures of the surface of the cerebrum; the cortex and fore-brain, the white substance of the hemispheres, the commissures and the corona radiata; the corona radiata, the corpus striatum, the thalamus and the subthalamic region; the structures at the base of the brain; the corpora quadrigemina and the origin of the optic nerve; the pons and the cerebellum; the roots of the peripheral nerves, the spinal ganglia and the spinal cord; the spinal cord and the commencement of the medulla oblongata; the medulla oblongata and the tegmentum of the pons; the pons; final review.

It will be seen that the lectures cover very completely the subject of the structure of the central nervous system. The illustrations are very clear and helpful. In most cases they have the German anatomical names upon them, but as these are explained beneath the illustrations, no confusion is created in the reader's mind; indeed, to a person with some knowledge of German, it is interesting to have the exact German equivalents of well-known English anatomical names. Altogether we think the book will be valuable to the specialist in nervous diseases, and especially to one who is a student of cerebral histology.

PRINCIPLES OF SURGERY. By N. SENN, M. D., Professor of Principles of Surgery and Surgical Pathology in the Rush Medical College, Chicago, Ill., etc. Large 8vo, pp. xiii, 611. Philadelphia and London: F. A. Davis, 1890. Price, cloth, $4.50, sheep, $5.50.

This handsome and well-illustrated book contains an exposition of the principles of surgery different from what has been usual in works on this subject. The difference is due to the great amount of space given to discussing the *rôle* played by micro-organisms in the various morbid processes coming within the domain of the surgeon. Pus, for example, is not described by its color, smell and taste, but—in addition to some of these—by its chemical and microscopical characteristics. Septicemia is divided under a number of heads, each of which is identified by the presence of a definite bacterium. So through the whole list of subjects considered—it is the bacteriological side which gets most study. The result is a book quite different from the general run of books in the English language on surgery, and a book for which there is a place in most libraries.

Dr. Senn has done his work well, having great familiarity with surgical literature, and an abundant clinical and experimental experience. His book is both interesting and instructive, and has been well printed by the publisher.

LITERARY NOTES.

—J. B. Lippincott Company will, beginning with April, issue quarterly thereafter, a work entitled "International Clinics." This work will comprise the best and most practical clinical lectures on medicine, surgery, pediatrics, gynecology, dermatology, laryngology, ophthalmology and otology, delivered in the leading medical colleges of this country, Great Britain and Canada. These lectures have been reported by competent medical stenographers and thoroughly revised by the professors and lecturers themselves. The object of the work is to furnish the busy practitioner and medical student with the best and most practical clinical instruction in concise form. Each volume will consist of over 350 octavo pages, illustrated with photographic reproductions of important cases.

CORRESPONDENCE.

Electricity and Pelvic Surgery.

TO THE EDITOR.

Sir: In your impression of March 21 (page 340), Dr. Horatio R. Bigelow makes some criticisms upon some remarks of mine touching the harmful effects of electro-puncture in treating fibroid tumors of the uterus.

My remarks were contributed to a discussion upon the treatment of such growths, which discussion was introduced by Dr. R. S. Sutton, of Pittsburgh, and afterwards published. Here are my remarks to which Dr. Bigelow makes objection: "Of late electricity has been much vaunted in the treatment of fibroid tumors of the uterus. Dr. Sutton merely mentioned this agent in his paper, probably purposely, because he knows that electricity does nothing towards arresting or removing these tumors. A peculiar feature about the application of electricity in pelvic surgery is that those who a

few years since denied the existence of certain forms of intra-pelvic diseases are now foremost in the diagnosis and treatment of these same diseases by electricity. The application of electricity by puncture is fraught with danger. The speaker has removed a uterine myoma by supra-vaginal hysterectomy, weighing sixteen and a half pounds, in which the entire anterior aspect, which had been accessible to electric treatment, was bound by dense adhesions to the omentum, intestines and abdominal walls, etc."

Dr. Bigelow pronounces the above to contain some "peculiar points," which points he takes up *seriatim* as follows:

"(1). Dr. Sutton, if acquainted with the statistics and history of gynecological electro-therapeutics, will not feel flattered at this surmise. The unimpeachable cases on record in which tumors have been arrested by electricity, are numerous and quite as reliable as are any statistics ever brought forward by any surgeon. If Dr. McMurtry does not know this—his argument would be akin to that of a 'lightning bug' who never owned a battery—if he does know that such claims are made, but refuses to accept them because they antagonize pet theories of his own, it is not polite to give utterance to such doubts, since men of equally honorable standing with himself have seen and reported such cases. I have seen quite a number 'reduced,' and so can any one else see these cases if he will. I have never seen a fibroid *disappear entirely*, but other men have, and I believe them. It is 'foolish talk' to reiterate all this, because all of it is a *fact*.

"(2). In no branch of medicine has a greater change taken place than in the pathology of female pelvic disease. What became of all these modern, high-sounding diseases, and of the women who had them, before the modern laparotomist was incubated? Who condemned abdominal surgery, not very long ago, but the surgeons themselves? Did women die of these diseases then, as they are since laparotomy has become a fashionable '*fad?*' It *is* nice of the doctor to give the 'lightning bugs' credit for recognizing and diagnosticating these troubles, early in their history, and for establishing a conservative system of treatment.

"(3). This objection is a mere will-o'-the-wisp of the doctor's fashioning. I am speaking, of course, of a puncture in the hands of those competent to make use of it. In the clinic, conducted by Dr. Massey and myself, cases are punctured, high intensities being used, and the patients go to their homes one-half hour afterwards. I do not advise this, but with such absolutely poor people, and with no beds at our disposal, we have no alternative. I *have never seen* any bad results following a fibroid puncture, and my experience has been an ample one. But even were it possible to show that such a process is attended with danger, what is the value of such an objection? Is not laparotomy — the alternative — a dangerous operation?

"(4). Dr. Baldy, than whom no man of equal age stands higher in the surgical literature of this country, told me only a few days ago, that he very rarely if ever had opened the abdomen for the removal of tumors, without finding extensive adhesions, and that a large majority of so-called pus-tubes were simply cases of chronic adherent salpingitis. So that all this rumpus about adhesions—these big tumors—how could it be otherwise, and by what process of ratiocination does one reach the conclusion that adhesions are engendered by electricity?"

In the present state of our knowledge, with the established results of the surgical treatment of uterine fibroids, it seems almost idle to answer such criticisms as the above; but the plea of conservatism (so-called) is so attractive to many, and so very misleading, that the facts should be stated. Permit me to call attention to Dr. Bigelow's first "curio."

In this he says "the unimpeachable cases on record, in which tumors have been arrested by electricity, are numerous." In the same paragraph he says, "I have never seen a fibroid *disappear entirely*, but other men have, and I believe them." Further on, in paragraph numbered 3, Dr. Bigelow states that "my (his) experience has been an ample one." So we have his own testimony, in his own words, that with an ample experience he has never seen a single case of fibroid tumor, in which the tumor disappeared under electrical treatment.

In his second paragraph, numbered 2, he presents a still greater absurdity. After announcing the great advance in the pathology of female pelvic diseases, he says: "What became of all these modern high-sounding diseases, and of the women who had them, before the modern laparotomist was incubated?" The logical sequence of such an interrogation can be best appreciated if we would inquire what result was obtained in

treating ectopic pregnancy before advancing surgical knowledge in the hands of laparotomists made clear the deadly nature of intra-peritoneal rupture, and a safe and efficient method of treatment? The absurdity of this mode of reasoning (if it can be so called) will be apparent if applied to any great advance in medical or surgical therapeutics, or to any scientific improvement, for that matter, in any department of human effort.

In paragraph numbered 3, Dr. Bigelow says he has never seen any bad results following fibroid puncture. In reply to this, I will say that I *have* seen the bad results of such puncture in the form of violent peritonitis and extensive adhesions, directly resulting from electro-puncture in the hands of those who, like Dr. Bigelow, consider themselves competent to make use of such treatment.

In paragraph numbered 4, Dr. Bigelow would seem to be ignorant of the simple fundamental fact that intra-peritoneal adhesions are the result of pre-existing peritonitis. Whatever begets peritonitis will produce adhesions; electro-puncture begets peritonitis at the point of puncture, often extending widely; and hence electro-puncture produces adhesions. No one claims that electro-puncture is the only cause of adhesive peritonitis. It is well known to experienced pelvic surgeons that tapping ovarian cysts with aspirator or trocar always produced peritonitis and adhesions at the site of tapping. Since the practice of tapping has been abandoned, this troublesome complication is much less frequently encountered in ovariotomy. For the same reason, electro-puncture is harmful in its results upon fibroid tumors of the uterus.

Ovariotomy is recognized as the most successful major operation in surgery. The mortality of supra-vaginal hysterectomy for uterine fibroids has been reduced almost to the same point. When treated thus, the results are perfect, the patient being entirely cured and restored to health and activity. A distinguished surgeon in Dr. Bigelow's own city has done thirty-eight consecutive, unselected, supra-vaginal hysterectomies without a death, in cases where the supreme indication was to save life. The operation of removal of the uterine appendages arrests hemorrhage and brings about atrophy of the tumor in less extreme cases, and has a mortality of only two and one-half per cent.

These results of the treatment of uterine fibroids upon sound surgical principles are established facts, demonstrated by the incontrovertible evidence of individual cases and personal experience. The harmful effects in the form, if inflammation and adhesions resulting from electro-puncture, are equally well known; and the inefficiency of the electric treatment has been conceded by many who intelligently and earnestly applied the treatment for a long period of time, and have abandoned it.

Yours truly,

L. S. McMurtry, M. D.
231 W. Chestnut St.,
Louisville, Ky.

Notes and Comments.

Partial Excision of Sternum for Melano-Sarcoma.

Dr. Herman Mynter, of Buffalo, N. Y., reports, in the *Annals of Surgery*, February, 1891, an interesting case of operation for melano-sarcoma of the sternum. He says that while excision of the sternum on account of caries of tuberculous or syphilitic nature has been done quite frequently, excision on account of malignant growths is so rarely performed that neither surgical textbooks nor works on operative surgery mention it. On looking over the literature at his command, he finds only two cases mentioned, one by Koenig, and one by Küster. Koenig's case was an osteoid chondroma which occupied the whole sternum with the exception of the manubrium and the processus xiphoideus. The operation was performed in the following way: Long, vertical skin incision, after which the costal cartilages were severed on both sides from second rib downwards. Thereafter the sternum was cut through, by aid of a saw, below the first rib. The sternum, with the tumor attached, was now lifted up with blunt hooks and carefully dissected loose from the mediastinum. During this proceeding both pleural cavities were torn open, but the tears were closed by pressure with antiseptic gauze until the skin-flap was in position covering the openings. The tumor was adherent to the pericardium, which was removed with success (?). The patient recovered, but died two years later from relapse in the lung.

Dr. Mynter's patient was a woman twenty years old, born in Ireland, who entered the

Sisters of Charity Hospital on November 14, 1890, with the following history: She is a domestic, and has been obliged to do a great deal of sweeping, during which the handle of the broom rubbed against her breast bone. She ascribes her complaint, a tumor over the sternum, to this cause. The tumor first appeared eleven months ago, and has been growing larger steadily until now it is the size of half an orange, and extends from below second to below fifth rib. Four months ago the glands in the right axilla commenced to enlarge and there is now found here a conglomeration of glands as large as two fists, completely filling the whole axilla, but yet somewhat movable. Two months ago the glands in the left axilla commenced to swell, and are now as large as a hen's egg. During the last few weeks the glands in both supraclavicular regions have commenced to enlarge. The tumor over the sternum is immovable, and presents a feeling of false fluctuation; the skin is normal in color and not adherent. She has sharp, shooting pains radiating from the tumor in different directions; has lately commenced to lose flesh, but is yet in pretty good general health. There are no symptoms of any growth in the anterior mediastinum such as hoarseness, difficulty in breathing or interference with circulation.

On November 15, 1890, an operation was done under ether-narcosis. Dr. Mynter made a U-shaped incision, convex downwards, from second to sixth ribs, about three inches wide. The flap was dissected up and the periosteum loosened transversely from the sternum above the tumor in healthy tissue, in order to shell out the tumor from the bone if possible. The tumor was surrounded by a strong fibrous capsule. On a line with the fourth rib the tumor extended into the sternum, and the capsule was necessarily opened here, and there was a discharge of a semi-fluid, black, grumous substance. The rest of the tumor was therefore removed from below upwards, by a similar process. The sternum was found quite extensively involved, presenting an irregular cavity as large as a section of a hickory nut, filled with the black, grumous substance. It was thoroughly scraped out with a sharp spoon. During this proceeding, the posterior lamina of the sternum was perforated. The opening was enlarged with chisels, and from this opening the posterior periosteum was loosened with a curved elevator, and the sternum removed piecemeal with cutting pliers from above the third rib to midway between the fifth and sixth ribs. About one-half inch of the third, fourth and fifth right costal cartilages were removed too, and the pericardium, which appeared healthy, was exposed for about six square inches. The skin flap was thereafter brought into place, and sutured, and a drainage-tube inserted from the lowest point into the cavity left by the removal of the tumor and the sternum. The enlarged glands were thereafter removed from both axillar and supraclavicular regions, drainage-tubes or catgut drains introduced, sutures inserted, and antiseptic dressings applied. The operation lasted two and one-half hours.

The further course was favorable. The temperature rose for a couple of days to 101° in the evening. The respiration was difficult and painful for some time until she learned to use abdominal respiration. The drains were removed on fifth day, and on the tenth day the wounds were healed and the patient allowed to sit up. She left the hospital on the fourteenth day, and so far, ten weeks after the operation, has no symptoms of relapse; she has gained twelve pounds in weight, and gone to work again as a domestic.

The operation performed differs from the one described by Koenig. He tried to extirpate the sternum *in toto*, and managed by that proceeding to tear open both pleural cavities. It is scarcely possible to have this accident occur when we first trephine the sternum, and then remove it in pieces with cutting-pliers. Dr. Mynter could, with the greatest ease, have removed the whole sternum in this way, but he stopped, of course, when he met healthy bone-tissue. The tumor being a melano-sarcoma, will, of course, return, and eventually kill the patient, but if it had been removed half a year earlier, before the glands were enlarged, there might have been better prospects of a permanent result. Dr. Mynter says he was severely criticized by several physicians for attempting the removal, they being of the opinion that such an operation was "little short of murder."

Medical Legislation in Missouri.

The *St. Louis Medical and Surgical Journal*, March, 1891, says: State Legislatures have always been "a source of innocent merriment," as the Mikado puts it. Our own is no exception to the rule. In fact, it seems that since the Farmers' Alli-

ance is in practical control of the House of Representatives, our lawmakers have let their fancies run riot. They do not seem to know what law is and they furthermore indulge in the fascinating self-deception that they can pass such enactments as seem most pleasing to them, irrespective of Constitution or any other such small hindrances to their untrammelled action in the premises.

One bright particular star, no doubt, has fallen into the clutches of a doctor at some remote period of time. This is the only way we can account for a remarkable action he committed not long ago in the introduction of a bill whose chief feature is the amusement it caused. We want every one to distinctly understand that this happened in the broad commonwealth of Missouri, and not in one of the effete States bordering upon the Atlantic Ocean. If we are going to have sample idiots we want them of the monumental kind, and we have one and we want to keep him as a sample. He imagined that an idea had struck him and he forthwith formulated a bill, the principal features of which provided for the regulation of the fees of physicians. The schedule is quite a liberal one, considering the source whence it emanated. Calls are not to exceed $1.00 each, and office consultations must not be charged for at a greater rate than fifty cents each. There are some other equally lucid provisions to the literary curiosity, but we forbear from enumerating them.

Our State Board of Health not long since held its annual meeting and the subject of medical education came up incidentally. Some of the members stated it as their firm and unalterable conviction that no diploma should be recognized unless the college issuing it required its possessor to have attended three courses of lectures in one or several reputable medical schools. Others of the members of the same Board gave it as their opinion that an attendance upon two terms of lectures was all-sufficient. To arrive at a definite conclusion it was decided to have a vote. When the result of the ballot was announced the discovery was made that the Board was evenly divided upon the question, with no hopes of obtaining a majority for either side of the question. What to do in such circumstances might have puzzled others, but the Missouri State Board of Health cut the Gordian knot and solved the difficulty in a very simple manner. The whole matter was referred to the State Legislature and it has been resting there ever since. We presume that it needs a prolonged rest and will get it. Our Solons are not particularly anxious to wrestle with the question and there seem to be indications that it will quietly slumber into non-existence unless some vigorous means be pursued to resuscitate it into the semblance of life.

We are certain that there will be other features of a medical character brought out in this Legislature before it adjourns. The Social Evil bill has a few; but what we want is a good, genuine "way-back" medical law (that won't hold water). We need it, as physicians are so thoroughly incompetent to manage their own affairs that they need the kindly and protecting care of the farmers to help them along.

Albuminuria in Acute Catarrhal Enteritis.

Dr. A. A. Netchæff (*Bolnitchnaia Gazeta Botkina*, states that there is very little said about albuminuria in acute enteritis in medical literature, although it is a very important subject. Works of a number of authors are quoted, one of whom reported twenty-five cases of cholera nostras, in nineteen of which there was albuminuria in various degrees, which disappeared in from two to three days. Bacteriological investigations revealed the presence of five different micro-organisms in the intestinal secretions. As a rule, it is alleged, it is hard to trace out the provoking cause of enteritis. Often the patients state that unwholesome food was taken, but frequently they cannot account for the condition. It is always unknown, the author says, what was the condition of the intestinal tract previous to the manifestation of the series of symptoms and—what is very important—what was the condition of the foods thought to be wholesome.

Three hundred and four cases of acute enteritis are mentioned which the author treated in his hospital. In sixty-five cases of those, the affection was traceable directly to the quality of the food used, and seventeen cases of the sixty-five had decided albuminuria. In the cases of enteritis without any traceable cause, albuminuria was not marked, in either per cent. or amount; in cases with chronic kidney affections the albuminuria was increased, and there was a decided acute renal exacerbation during the attack of enteritis. The number of *post-*

mortem examinations of the patients who succumbed to the enteric attacks convinced Netchæff that the kidneys suffer more or less, and the food is considered to be the source of the supply of poison to the system in general. In a few cases indican was found to be present simultaneously with albuminuria in enteritis. As indican appears usually during decomposition of matter especially in the small intestine, and as the presence of indican coincides with temporary albuminuria in enteritis, it is evident that both are provoked by decomposing matter in the intestine.

Netchæff concludes by saying that the acute exacerbations of renal disease during an enteric attack rarely passes off without leaving some impression on the already affected kidneys, and that in some patients who have not the choice of their food certain renal affections could probably be traced to the latter.

Ways in which Syphilis may be Spread.

Dr. Holcombe writes in the *International Dental Journal:* "I recollect an instance that occurred on board the same ship with Horace Greeley's wife. Her little child was taken up by a stranger and kissed. The mother took the child from him and said: 'Sir, I do not allow you or anybody to kiss my child.' She took her handkerchief and spat on it and rubbed the lips off. This kissing business is often perfectly terrible in results. Some nurses kiss a child on the lips, and kiss it on the nose and ears and kiss it all over: and I have not the least doubt that syphilis is conveyed to many innocent persons by this habit. I should like to ask if the dry powder of syphilitic chancre, having been rubbed off, like vaccine virus, and blown through a room, would, by being inhaled, be the means of communicating syphilis. I heard Ricord once say that many cooks would communicate syphilis to a whole family; the cook would have a sore on his lip and would not think anything about it, and he would taste the different dishes and put his fingers into them—and all know the French cook has a habit of handling the meat with his fingers—and many people undoubtedly have contracted syphilis from food handled by cooks. It was the old-fashioned way in hotels to have the towels on a roller for the common use of guests, and I remember once on a steamboat there was a tooth brush for the whole crowd. I have no doubt that tooth brushes sometimes used by several younger members of a family have been the means of communicating syphilis. I have had many patients come to me and say that they caught the disease from a water-closet, and I have no doubt that many cases of gonorrhœa and syphilis can be thus communicated. I think they should be under direct sanitary inspection, just as much as the foul air that comes from the sewer. Not long ago I was in a cigar-maker's establishment and I noticed that every cigar-maker, when he finished the end of a cigar, wet the forefinger and thumb with his lips to point it nicely. I wondered at the time if he had a lip-chancre; and I question if the disease has not been given to many persons in that way. I know of a case where, a few days ago, a lady kissed every female in the room, and one of the persons in that room I know had syphilis. Some people make a business of kissing everything, kissing animals, birds, dogs and cats, and it is very suggestive of the transmission of disease. The habit of putting money into the mouth, that some people have, is one that might lead to syphilitic infection. A butcher or grocer will often hold a half dozen bills in his mouth, and grown people will put silver pieces and pennies into their mouths; and I have wondered that the habit has not been more productive of disease than we have observed. At all events it is well to have our attention and that of the public called to the means of contracting syphilis and other diseases."—*Druggists' Circular*, March, 1891.

Burial of So-called Stillborn Children.

The *Lancet*, March 21, 1891, calls attention as follows to a matter of importance in this country as well as in Great Britain. "The question recently asked by Dr. Cameron in the House of Commons respecting the interment of stillborn children, and the reply of the President of the Local Government Board, call for more serious attention than it is likely to receive. Dr. R. Rentoul has just issued a pamphlet in support of his active opposition to the Midwives' Registration Bill, in which he states that he has ascertained by personal inquiry that during the year 1889 there was interred in seventy-one burial board cemeteries, as stillborn, the bodies of 6,321 infants; and that there are

no fewer than 1,100 such board cemeteries in England, in addition to the parish churchyards, in which the proportional number of this class of burials is supposed to be larger than in cemeteries under the control of burial boards. Dr. Cameron, knowing the very loose and unsatisfactory system under which stillbirths are certified for burial purposes under the Births and Deaths Registration Act, 1874, asked the President of the Local Government Board for a return of the total number of infants interred as stillborn during 1890 in England and Wales. The answer to this question obviously suggested by the facts of the case was that, as there is no system of registration of stillbirths in England and Wales, it would be impossible to furnish the return asked for. It is seriously to be regretted, however, that the importance of this subject, from many points of view of deep public interest, did not suggest the possibility of providing some remedy for an evil which amounts to a grave public scandal, rather than suggest the assertion of a simple *non possumus*, a position too readily assumed by Government departments as a foil to suggested reforms. It is needless now to enumerate the many evils that arise from the present loose system of certification of stillbirth; but we may point to one which is but too likely to be overlooked—its effect upon vital statistics which constitute one of the most powerful and stimulating factors of health progress. Vital statisticians have in recent years been startled by the constantly rapid decline of birth-rates and of death-rates. It is obvious that so-called stillborn children are not recorded in the birth or death registers, and in the interests of trustworthy statistics, it is therefore of real importance to know what truth there is in the assertion of the amount of interment of so-called stillborn infants that is going on around us, practically unknown and unchecked. The results of Dr. Rentoul's private inquiries are striking enough to call for Government inquiry; and there seems to be only one real difficulty in the way of such an inquiry. This difficulty is the apathy of the Government in the matter. All burial grounds and all burial authorities are, it is supposed, under some kind of control exercised by the Home Office. Why then should not the inquiry, so urgently needed and called for, be undertaken by the Home Office? and why should not all burial authorities be required to furnish annual, or more frequent, returns, showing the number of burials of so-called stillborn infants, accompanied by the actual certificates which the Births and Deaths Registration Act, 1874, requires, as authority for the burial of any child as stillborn? Such a course would supply the means for a kind of registration of stillbirths, and would also prove a real check upon the gross abuses of the present system, which are very generally known to exist."

Ichthyol Varnishes.

In speaking of ichthyol as an external application, a reviewer in the *British Journal of Dermatology*, April, 1891, says: One great disadvantage in regard to the employment of ichthyol to limited areas of disease has been the impossibility of applying it in any way that was at once easy and efficacious. The pure drug, apart from its unsightliness and objectionable odor, will not dry, even if spread in a thin layer, but remains for hours moist and sticky, and the various combinations with dextrin, gum and gelatin-glycerine paint have been found in practice to be inefficacious. Ichthyol collodion promised better, but the irritation which is caused by removing it is such as to more than counterbalance its beneficial effects. In the case of patients who are only able to follow out treatment at night the removal of these firm adhesive layers each morning, therefore, renders their employment impossible. In order to overcome this difficulty and to produce an impermeable layer of ichthyol, which could be easily and quickly removed without irritating the skin, Unna instituted a series of experiments in conjunction with Dr. Helmers, and arrived at the following formula, which he finds to answer his purpose fully:—

Ichthyol	40 parts (by weight).
Starch	40 parts.
Albumin solution concentrated.	about 1–1½ parts.
Water . .	ad. 100 parts (*i. e.*, about 20 parts).

The constituents must be mixed in definite order, the starch must be moistened with the water, the ichthyol then rubbed well in, and finally the albumin must be added. The concentration may be regulated by the thickness of the layer, the first application being wiped off with a moist cloth so as to leave the finest possible coating. Even a thick layer drys very rapidly, and can be washed off at any moment.

An ichthyol-carbolic acid varnish having the same properties can be made in a similar way, but, of course, with the omission of the albumin. The formula is:—

Ichthyol	25 parts.
Carbolic acid	2.5 "
Starch	50 "
Water	22.5 "

The ichthyol and carbolic acid are dissolved in the water in a gentle heat, and the starch then added.

The first preparation, *vernisium ichthyoli*, is recommended in acne where the skin is irritable, in rosacea seborrhoica, and in rosacea simplex, in ulerythema centrifugum (one form of "lupus erythematosus"), intertrignes, tubercular eczema, seborrhoic eczema and erysipelas. It may with advantage be made a basis of other reducing and antiparasitic substances, such as chrysarobin (2.5 per cent.), which may in this form be applied with confidence to the face, pyrogallol, resorcin and sulphur, for the treatment of parasitic diseases, such as certain eczemas and psoriasis. But in this case it is better to mix, for every quantity of new substance added, an equal quantity of linseed oil, which is at once a reducing agent and a rapid seccative.

Bad Effect of Poultices for Spreading Ulcers.

Surgeon R. Ross, of Bangalore, writes in the *Indian Medical Gazette*, March, 1891, that in October and November, 1889, being then in Upper Burmah, previous to proceeding on the Chin Lushai expedition, he had the opportunity of treating a large number of cases of spreading ulcer on the feet of mule drivers attached to the force. These ulcers were of an alarming nature, spreading rapidly sometimes to the size of a saucer and even burrowing between the bones. Several deaths occurred in neglected cases, and in one case amputation of the foot was necessary. The sores were evidently microbic, and were of the same nature as the spreading sores on the backs of some of the mules. Flies probably carried the infection, but the mules' hoofs appeared, by the result of kicks, to be much imbued with the poison. The sloughing action implicated as a rule only the true skin, and in one night a quarter of an inch of tissue would be destroyed. The treatment was at first the usual—nitric acid, hot poultices and opium—but in many cases Dr. Ross was obliged to leave off the hot poultices owing to the great pain they caused. In a few of his last cases he was astonished to find that the sloughing ceased when the sore was dressed simply with a wet piece of lint placed upon it. At the same time he was informed by the Veterinary Surgeon of the expedition that those mules whose sores were left undressed often recovered marvellously.

At the end of June last, Dr. Ross was called to see a woman, sixty-nine years old. She was suffering from two bruises, one on the right shin, the other on the inside of the left ankle. The skin over both bruises had mortified to the size of a shilling. The wounds long remained in a quiescent state, being only lightly brushed with oil. At last, in order to stimulate them, hot poultices were ordered. The skin now rapidly broke, showing a foul ulcer beneath. They were both cleaned out with pure carbolic acid and poultices were continued. The upper and slighter wound healed shortly, but the lower spread in resistance of frequent carbolic acid swabbings. At last, when the ulcer had become two and one-half inches in diameter, nitric acid was applied to the sloughing tissue (there was a white, evidently microbic, infiltration of the true skin causing the slough). The neighboring parts were perchloridized, and carbolized charcoal poultices were applied. Next day Dr. Ross found that the sloughing had continued as if nothing had happened. Moreover, a minute drop of acid had fallen from the pipette on to the healthy skin one-half inch from the edge of the wound. The sloughing had commenced in this spot also. This did not argue well for nitric acid. Finally, in despair, he determined to leave off the hot poultices; and the sloughing action ceased from the moment the last poultice was taken off, and the ulcer completely healed. Dr. Ross thinks that the nitric acid failed for one or both of these two reasons: 1, it is known that microbic infiltration is often very extensive in the neighborhood of microbic lesions, so that the destruction of tissue by nitric acid would have to be very great to be effective, too great, in fact, for the present case; 2, many recent investigations have shown that microorganisms which may exist quite harmlessly in the blood will immediately attack an injured part, say a broken bone. It is obviously useless, therefore, to apply nitric acid to a wound when the malignant organism

comes from the blood itself. In this case the fallen drop of acid itself immediately started a new circle of disease. The reason why poultices may be bad is that they maintain exactly the conditions of warmth and moisture necessary to the growth of the pathogenic organism.

Tuberculosis Treated with Hypodermic Injections of Iodoform and Guiacol.

Dr. Picot, Physician to the Hôpital Saint André, Bordeaux, at a recent meeting of the Académie de Médicine, Paris, read a long and highly interesting paper on the above subject, the following abstract of which is taken from the *Medical Press*, March 25, 1891.

For the last two months the author had been making experiments at his Clinic in the Hôpital Saint André, at Bordeaux, on the treatment of phthisis, but before proceeding to describe the treatment he followed, he wished to declare that he did not bring forward a cure for the disease, for in his opinion, and in that of his colleagues, the day has not arrived when it might be affirmed that an infallible remedy for pulmonary tuberculosis has been discovered. There are patients, with whom no treatment will succeed, for no therapeutic methods could reorganize lungs that have been destroyed by the ravages of the disease. Lately an example of the absurdity of therapeutic conceptions pretending to cure tuberculosis in a general sense has been before the world. Dr. Picot was much more modest in his pretensions, and desired only to relate the result of his treatment of pulmonary tuberculosis and pleurisy of the same origin. He would remind his colleagues that, as the illustrious Trosseau had affirmed, pleurisy is, in the large majority of cases, of tuberculous origin. The therapeutic agent which he was bringing before his colleagues was a mixture of iodoform, guiacol, olive oil and liquid vaseline. The solution is perfectly transparent, and each hypodermic syringe contained one-fifth of a grain of iodoform and one grain of guiacol. The liquid as indicated was employed in subcutaneous injections, and the position chosen was the supra-spinal fossa as it is a point free from any compression.

The first condition, said the author, which imposes itself on the therapeutist in the use of an agent, is not to do any harm, *primo non nocere* is the old adage, and which ought to be respected even in this daring age. He affirmed then at the outset, that the injections of the liquid gave rise to no evil consequences, neither locally nor generally. At the point of injection no redness or swelling occurs, nor is the part painful. The absorption of the medicine is proved by the fact that it appears in the urine not, however, as iodoform, but as iodide of potassium, on the third day after the injection. As to the general effects of the injection, they were never hardly noticed except when the patient had fever, and then appeared as profuse sweating over the whole body, which set in about a half an hour after the injection, and lasted one or two hours. When past, the patient felt a *bien être*, and the fever lowered one degree. Examining the therapeutic effects of these injections, Dr. Picot said that all his experiments were made openly, before all his students and several army and navy doctors, so that all was done above board. Twenty-five patients were treated up to the present, of whom fifteen were men and ten women, of this number three succumbed, as they were in the last stage of consumption, the fever in no way being abated by the injections, but each of them expressed themselves as better for the treatment, and the expectoration diminished considerably in quantity. The *post-mortem* showed, however, the good effects of the injections in the fact that the vomicæ were found dried up, the caseous secretion was entirely absent. All the other patients were in the second stage of the malady. One of them, a man, 54 years old, entered the hospital in October last. His father died from consumption. This man had coughed for the last year. On examination, the chest showed dulness in the subclavicular regions on both sides, and on the right side sibilant râles; bacilli were discovered in the expectoration. The injections were commenced in January, and immediately the patient felt better, the expectoration diminished and the body gained in weight. At the end of a month sonosity was well marked at the seat of former dulness, and all râles had disappeared, while the respiration became normal. A week subsequently the man left the hospital in a very encouraging condition. The injections were made every day, at the dose of three syringes.

Another patient, 35 years old, entered the hospital in the middle of January, four

years previously he had a pleurisy, which lasted two months, last year he had the influenza and coughed ever since. He was very emaciated and suffered from night sweating and fever. He spit a great deal, and bacilli were found in the expectoration. Auscultation revealed the existence of skodic murmur on the right side and dulness and râles in the third intercostal space. On the left side broncophony was noticed and other symptoms, leaving no doubt of the character of the affection. On January 20, the injections were commenced at the dose of a syringe a day, forty-eight hours afterwards the expectoration diminished by two-thirds. Three injections daily were then practiced with the result, that in a week the patient expectorated no more, and the cough had totally ceased. On February 9, he quitted the hospital quite satisfied, although the skodic murmur persisted, all râles had ceased and sonosity had returned in the points of dulness. After passing more briefly in review several other cases which terminated in a similar satisfactory manner Dr. Picot said that, although the results must be admitted to be very encouraging, he was far from pretending that he had discovered a cure for the disease. It is well known how reserved one ought to be in such cases, and how difficult it is to affirm that a patient is cured. In order to be sure of it, the case should be closely watched for years. But with the treatment he had been following for the last three months, he obtained such results as to lead him to believe that it was possible to arrest the progress of the disease. In any case for the thirteen years that he had been teaching medicine in the Bordeaux Faculty, he never arrived at the success he has experienced by the treatment he had just explained. By these injections the general condition of the patient was greatly improved, the expectoration and the cough ceased, as well as the fever and the night-sweats, and the vomicæ in certain cases dried up, all crepitation disappearing. Is it a cure, asked, in conclusion, the author? Time alone can tell, but up to the present he was happy to have been able to give some hope to so many unfortunate patients.

The formula used is as follows:

℞	Iodoform	grs. vj
	Guiacol	grs. xxxij
	Olive oil	℥iv
	Liquid vaseline	℥iv

A hypodermic syringe of this solution contains one-fifth of a grain of iodoform and one grain of guiacol. One to three injections daily.

Diagnosis of Whooping-cough with a Tube in the Trachea.

Dr. James Finlayson, physician to Glasgow Western Infirmary, reports in the *Archives of Pediatrics*, April, 1891, the following interesting case. A boy, six years old, was admitted to the Royal Hospital for Sick Children, Glasgow, on November 6, 1888. He was in such distress from urgent dyspnœa, due obviously to laryngeal obstruction, that in about an hour after his admission tracheotomy was performed by Dr. Hector C. Cameron. The breathing was at once relieved. After the operation the boy seemed to do well enough, but he continued to have a very troublesome cough, which was supposed to be connected, in part at least, with the irritation of the tube, etc. On the eighteenth day the tube was removed, and he did well enough without it. The cough still continued. After the removal of the tube the peculiar character of the cough began to excite suspicion, and in three days the resemblance to whooping-cough became so great that his removal to the isolation ward was ordered; in another three days the diagnosis was complete, and he was removed to the whooping-cough wards of the Fever Hospital, on November 30. The report from there was that the case proved to be a mild one; the tracheotomy wound healed in a few days, and he was dismissed well on January 12.

Inquiry of the parents elicited the fact that others in the family, as well as this boy, were affected with a cough, which, after the patient's admission, had developed the character of whooping-cough in them also.

The case was, no doubt, one of whooping-cough, complicated with laryngitis, suddenly presenting a grave form of obstruction. The idea of whooping-cough never entered my mind till after the tube was removed from the trachea, although the irritating sound of the coughing, with the air rushing through the tube, was heard repeatedly, and its cause could not be ascertained on physical examination of the chest. Of course the presence of a tracheotomy-tube necessarily interfered with any manifestation of the spasm of the glottis, on which we rely for the most characteristic sign of this disease. The effect of the tube completely misled the diagnosis.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

Clinical Lecture.

COMPLETE PROLAPSE OF THE WOMB, BLADDER AND VAGINA, TOGETHER WITH AN EPITHELIOMA OF THE LATTER.—PAROVARIAN CYST.—ADHERENT PLACENTA.

BY WILLIAM GOODELL, M. D.

PROFESSOR OF GYNECOLOGY, UNIVERSITY OF PENNSYLVANIA.

Gentlemen:—The first case I bring before you is that of a woman who has come from a distance to see what can be done for her. She is sixty-three years of age and has been a sufferer for a long time. Her condition is truly distressing. In merely taking a glance at her, I can see that she has an arcus senilis, and that the calcareous degeneration of her blood-vessels is quite marked. Moreover, she is emaciated and broken down.

Upon inquiring into her history more closely, I find she has been married, when she was a young woman; that her husband is still living; that she never has had any children; and, that her genital organs have been in this prolapsed condition since she was a girl. Cancers of the cervix generally come from lacerations, which latter, from being the seats of fungous degeneration, become worse and worse, until malignant disease is developed; so that old maids have fibroid tumors; mothers have epitheliometa, and sterile wives have ovarian or tubal disease. Of course, these statements are very broad ones, and are subject to many exceptions.

In the present instance, the facts that the bladder is completely prolapsed and that the urine is constantly dribbling over the vagina are the two main local causes in the production of the epithelioma here noticed; but I cannot tell to what extent they have contributed to this effect, nor why the growth is situated on the left inferior wall of the vagina, as it now stands in its inverted condition.

The pain that she has suffered from this growth has not been very great nor has it been constant; because the vagina is not a very sensitive part, nor is the cervix uteri. Therefore, epitheliometa and such growths on these parts are misleading; they are often overlooked for a long time, and the patient may allow them to go on, until she is aroused to her condition by the fœtor, bleeding, and her more or less impaired health; she then applies to a physician who insists upon a thorough examination and finds that the disease has so far advanced that he can do but little beyond rendering the balance of the patient's life more comfortable.

When the disease occurs within the uterus, the amount of suffering occasioned may be truly distressing, and it is useless to restrain the patient from the free use of opium or from anything else that may afford relief. (The patient was here removed.)

In dealing with this woman I told her the truth and nothing but the truth; yet I did not tell her the whole truth, because I was afraid that the shock and the distress occasioned thereby would be too great for her. I informed her that she had an epithelioma, and that any operation at her age would be almost useless.

My treatment will be to apply to the foul-smelling surface, a piece of lint or cotton, wrung out of a one to four thousand solution of the bichloride of mercury, in order to lessen the danger of systemic poisoning, and also, to destroy the fœted odor. The stench that clings to the hands of the surgeon from merely being in contact with such diseased structures is truly disgusting, and the method I resort to in my own person to destroy it, is this: I begin my course of disinfection by washing my hands in soap and water; I next wash them in turpentine, ether or alcohol,—whichever one happens to be most convenient. I then give them another washing in

soap and water, and finish my course of antiseptic cleaning by rinsing them thoroughly in a one to five hundred solution of the bichloride of mercury. All these precautions should be taken in going from one patient to another, lest disease germs be carried, and we thus become the seat of infection to those whom we wish to cure. The clothes may also carry germs, so that they should always be protected during our operations with gowns or aprons, which have been rendered surgically clean for this purpose; or, what is best, let our outer garments, at least, be changed, before going from an infected patient to another.

In the present case, I shall advise that it be suggested to her physician, so soon as she returns home and is well rested, that he apply to the ulcerated part, a solution of fifteen grains of the bichloride of mercury in one ounce of flexible collodion. This will cause a slough, leaving a clean surface more amenable to treatment than is the present one. She is also to be placed on the use of arsenic, beginning with one drop of Fowler's solution and gradually increasing that amount until she reaches as much as fifteen minims after each meal, or until the stomach rebels. The manner in which this drug exerts its beneficial effect is by means of its alterative action. Of course, I do not practically understand much about what this means, but I do know from a long clinical experience, that the remedy does good; and I can here recall the case of a man who submitted to numerous operations for an epithelioma of the lip, and who was finally permanently cured by a course of this medicine.

PAROVARIAN CYST.

The next case, is that of a woman, aged forty-two years, who has been married eighteen years, and has given birth to nine children. Eighteen months ago she suffered with aphonia, which must have been the result of some nervous trouble. She was also, a short time since, in bed for four weeks, during which time she did not suffer much pain, but, four times she managed to pass, from the vagina, as much as a bucketful of clear semen. After each of the aqueous discharges, the swelling of the abdomen became less for a while, at least; her other symptoms subsided, and she became very much better.

There is but one avenue from the abdominal cavity to the vagina, and that is through the Fallopian tubes. It is impossible to believe that the growth noticed in this case is a tubal tumor; because such tumors are smaller, and give more pain than this one has caused. Now, at times, an ovarian cyst is communicable with the tubes, and this will explain these repeated emptyings and refillings, resulting, too, in so little systemic disturbance. But, whatever it is, I shall now begin a systematic examination, in order to find out.

In the first place, I must decide whether the abdomen is enlarged from the presence of something really within and distending it, or whether this enlargement be merely owing to increase of fat in the abdominal walls. This latter fact is always to be borne in mind, because it is a rock upon which young physicians sometimes go astray. About the climacteric, a woman begins to dodge her periods, or to miss them altogether. She increases in abdominal size, and imagines herself to be pregnant; if she be a multipara, having the same signs and feelings as she did at her previous pregnancies; or, if she be a primipara, experiencing them with even greater evidences than ever did her more fruitful sisters. Arrangements are made for the birth, which, however, does not take place. The family is disappointed, and the young doctor is mortified. This occurrence once happened in the life of an English Queen, much to the disappointment and even disgust of her political party, which was looking to her for an heir. How, then, am I to determine whether this enlargement is from a distension within the abdomen, or whether it is merely from a thickening of the abdominal walls? It is done in this manner: I press with one hand deeply on one side of the abdomen, and then strike the opposite side with my other hand. I can feel the thrill of the vibrations as they are transmitted through the fat. But, by getting my assistant to put his hand between mine, the thrill that is transmitted only by the fat is stopped. The vibrations in the substance below, or through the underlying strata are still transmitted; but they are deeper and they vary from the fat vibrations. The difference in the time or intensity of the transmissions of the vibrations helps me to tell also whether I am dealing with a fluid or a solid tumor; because the speed or fineness of the thrill varies according to the solidity of the transmitting medium. This helps me to exclude a solid tumor, apart from the common senses of touch and of feeling; apart from the double touch, or the necessary consideration of the much more serious symptoms which a solid tumor of any kind would cause.

After arriving at the fact that I have a

liquid to deal with, I next have to decide whether there is a cyst or whether the fluid is loose in the abdominal cavity. I proceed to find this out by this mode of reasoning: If the fluid were loose, there would be dullness in the flanks, as the woman lies on her back, owing to the liquid seeking the lowest position. On the other hand, I would find resonance—as I do in this case—in the umbilical region; because the buoyant intestines would be floated up from below.

Examining per vaginam, I find that there is a small tear on the right side of the cervix. The womb is freely movable and measures plus three inches. Therefore, there is no solid tumor, and not finding any remnants of an ovarian cyst, I can yet state that I have made my diagnosis by finding nothing.

There is but one affection that would present itself as the diagnosis in this case, and that is a parovarian cyst. A parovarian cyst! you say, and what, pray, is that? As yet I am unprepared to answer this question with complete satisfaction to myself; but I know that it is thought to be a dropsy of one or more of the tubes of the parovarian. This word means near the ovary, and the name is given to several tubes on each side, which lie between the ovary and the Fallopian tubes. When one of them becomes cystic, the tumor may cause some pressure upon the ovary and give pain. It contains fluid as clear as spring water. It is highly refractive and greatly magnifies any object placed in the bottom of the vessel containing it. Just here I recall the case of a wife of a physician who had one of these parovarian cysts. It burst seven different times, causing a general collapse, together with the discharge of a large quantity of urine. It was finally removed by me. I would also mention that the fluid in the case of this tumor was slightly greenish. When these cysts collapse they generally leave nothing that can be felt because their walls are so thin. When tapped they may not return, but generally they do and in time they have to be removed. Sometimes this removal can be effected without disturbing the ovary on that side; but usually the ovary is also implicated and has to be removed at the same time. The argument advanced for the removal of this growth is that there is a tendency in some cases for it to become a papillary carcinoma, especially when tapt.

ADHERENT PLACENTA.

The next and last case which I shall bring before you to-day, is a woman, who was delivered of a fœtus, two months ago, and since then she has suffered with metrorrhagia, owing to the adhesion of parts of the placenta, which were not removed at the time of confinement.

The womb measures plus three inches. There is now, and has been, since the labor, considerable bleeding, so I very carefully introduce my fenestrated forceps into the cavity of the uterus and upon removing them, I bring out a piece of the placenta. This immediately stops the bleeding. I now re-introduce the forceps and succeed in getting out another piece of the adherent membrane.

The placental tissue has had during these two months a vital connection, and has, therefore, not undergone putrefactive changes. I have removed a scroll-like placenta after seven months, and have found it undecomposed, because it had been all the time adherent.

My first measurement of the uterus gave me a plus three inches. It now measures four inches. The womb is larger than what it first seemed. Previously, when I introduced my sound, it rested on a piece of the placenta, which I have now removed.

If it be necessary to tampon in this case, I shall plug the cervix—not the vagina—with iodoform gauze, leaving a little piece of it protruding, by which the tampon can be withdrawn at any time. I shall not tampon if I can avoid it, because tamponing interferes with the firm contraction of the uterus.

Be sure to have a fenestrated forceps among your instruments. It is especially valuable after criminal abortions, in which cases, parts of the placenta are so often left adherent for the following reason: In natural abortions the ovum becomes, or rather has become, a foreign body, it has been detached from the endometrium; but in criminal abortions the fœtus comes away, but parts of the membrane remain attached to cause hemorrhage and septicæmia. I often compare the results of a natural and of a criminal abortion with the falling off or dropping of a defective apple, or one that has been stung by an insect, to the violent tearing off of a green apple. The one drops off; the other is broken off. The one has its connection severed by nature's amputation, disease; and is removed so gradually that the parent stem does not suffer. Whereas in the latter case, the fruit is violently torn from the tree and a bleeding branch is left.

Gum chewers' cramp is a muscular incoordination similar to the cramp of writers, telegraphers, etc.

EMPHYSEMA.—GRIPPE AND ITS COMPLICATIONS.—CHRONIC HYPERTROPHIC CIRRHOSIS OF THE LIVER.

BY FRANCIS DELAFIELD, M. D.

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

Emphysema.

Gentlemen: I present to you to-day a man 52 years old, a laborer by occupation, who says that he was in good health and able to do his usual work until six months ago, when he began to develop symptoms of catarrh of the nose and throat, and, also, some bronchitis. He has a cough, complains of dyspnœa on exertion, and has palpitation of the heart. From the time he speaks of, that is six months ago, he has been getting steadily worse, and has been losing considerable flesh and strength.

On observing this man, we find that he is badly nourished, and has the expression of a person who is suffering from some real illness. Examination of the lungs gives us the physical signs of emphysema, with pleuritic adhesions over the top of the left lung. His heart is distinctly hypertrophied and dilated, but I can find no murmur present. He has a large heart, perfectly regular and forcible enough in its action and, if anything, a little exaggerated. There is some thickening of the radial and temporal arteries. He has a full and rapid pulse, but without any increase in tension. His urine has been examined a number of times, has a specific gravity of 1017, but contains no albumen.

The diagnosis of this man's trouble is by no means clear to me. He has evidently emphysema, but emphysema of itself is not sufficient to account for his present condition. There is no apparent change in the valves to any considerable extent, there is no evidence of any kidney lesion, no contraction of the arteries, nothing in fact very obvious to account for this marked increase in the size of his heart.

We might suppose this patient to have a chronic nephritis, but he should then have a heart simply hypertrophied, and not dilated and hypertrophied at the same time. We might suppose he has a chronic endo-arteritis, but then also there would be hypertrophy and not dilatation. Though his heart is increased in size, his circulatory system is little, if any, changed. The pulse of this man seems to me to point to some febrile movement, and I should be inclined to think the real cause of his illness is one of those irregular fevers that belong to New York and its vicinity, and which sometimes continue for a considerable length of time. I would imagine the best thing for this man to do would be to go into some hospital where he would be put to bed and taken care of. The medicine which we usually give for such cases, if it should turn out to be one of continued fever, would be Warburg's Tincture, either in the form of the tincture or of capsules.

Grippe and its Complications.

The next patient is a man aged 39, who has evidently been suffering from an attack of the grippe, which began about a week ago, and he is not apparently free from it yet. The form which the disease has taken with him, has been of the ordinary character. He had first a fever, with frontal headache, which is quite characteristic, and an inflammation of the pharynx. He also had a feeling of depression, and was confined to his bed for some time. Although the first symptoms of the attack have passed away, he is still suffering, as many of those patients continue to do after the acute stage of the disease has passed.

The irregularity of this man's heart action is, I think, the result of the grippe. Probably, before the attack, he had a heart somewhat enlarged and perhaps not perfectly regular, but still it was a heart that gave him no trouble. He was able to work and felt tolerably well. Just before coming to this clinic I saw an old gentleman who had developed the same cardiac condition from the same cause as this man has. He was 70 years of age, and previous to the attack had enjoyed good health and had no idea there was anything the matter with his heart. He had an attack of the grippe two weeks ago, and as a result of this, his heart, which was somewhat large, has been doing its work very badly indeed, so that he was unable to lie down in bed without being propped up with pillows.

This is one of the many disagreeable features of this particular disease. It seems to evoke diseases which had been quiescent and had given the patient no trouble till its onset. These cases of grippe should, I think, be handled with a great deal of caution when the disease manifests itself with any great degree of severity. I confess that this year I think very much more seriously of

the disease than I did last year when it first made its appearance in our midst. Of course, the very worst feature of this affection is the pneumonia, which accompanies it; and, although having all the clinical characteristics of the pneumonia of last year, it is, however, of so much more fatal character that I consider it extremely desirable on the part of the patient, the moment he feels an attack of the grippe to go at once to bed and stay there till the fever has entirely disappeared; and even after that to wait a few days before he undertakes to do any kind of work. In this way he is less apt to have a complicating pneumonia than if he were to be up and about.

The type of the pneumonia that accompanies the grippe this year is characterized by an excess of bronchitis and an inability of the right heart to force the blood through the lungs. As a result of this condition of affairs the patient very soon develops a sibilant and sonorous breathing over both lungs, then coarse and subcrepitant râles, and he does not cough up very much mucus. As a result of this, the bronchi soon become filled with mucus, and the inability of the right heart to force the blood through the lungs shows itself in a general venous congestion which becomes more and more marked, and the patient's breathing, as a result of these conditions, becomes worse and worse, and so he goes on till he finally dies. A great many patients die in this way the first twenty-four hours after the attack of the pneumonia, while others last three days or more before they succumb to the disease.

Such cases of pneumonia are made even still more unsatisfactory for the reason that the ordinary means of treating this condition are of such little avail. Generally speaking, a general bronchitis can be relieved a good deal by efficient cupping, but this procedure is of no use whatever in the bronchitis of these patients. In ordinary cases of pneumonia cardiac stimulants have been found useful while in these cases their influence counts for nothing. A combination of venous congestion and feeble heart is usually beneficially affected by hypodermics of nitro-glycerine, but in many of these cases of pneumonia nitro-glycerine is of no use whatever.

So you can readily see why I look upon this complication of the grippe as such a serious matter, and why I advise you to take every precaution against it; and, as I have already said, the moment you begin to have the first characteristic symptoms of this affection, tell your patient to go to bed and wait there till he gets better, and not expose himself to the danger of going out of doors.

Chronic Hypertrophic Cirrhosis of the Liver.

The next patient I present to you came here, for the first time, last December. Six months previous to that time he complained of pains in the back, his urine was yellow in color and his stools white. He then began to notice a lump in the hepatic region and began to lose flesh and to develop some jaundice. Since that time these symptoms have become somewhat modified in character. His jaundice has diminished in intensity and the skin of the face has assumed that dusky, brown hue that you now see. The general appearance of the man is not at all very bad. The increase in size of the liver is symmetrical and involves both the right and left lobes, and these project down into the abdominal cavity to a distance of some twelve inches from the free border of the ribs. The liver appears hard and nodular, but the spleen is of normal size, so that the liver in its increase has not offered any obstacle to the circulation of the blood through that organ. The blood circulates through the liver as usual and on that account we have no dropsy, and no enlargement of the spleen. This man then has a condition of the liver known by the name of hypertrophic cirrhosis.

The jaundice in this case is evidently of an obstructive kind and due to one of three causes, viz.: A calculus situated in the common bile duct; a chronic catarrhal condition of the common bile duct, or a new growth situated in its wall. We can, however, exclude a neoplasm as the causative factor in this case, for he would, no doubt, present a much worse condition physically than he at present exhibits. The diagnosis, therefore, rests between the other two conditions, and we are not now in a position to make a positive differential diagnosis. The probability, however, is that this man has been suffering all this time from a chronic catarrhal affection of the common bile duct.

The question of treatment next comes up for consideration. This patient has been given cold water enemata and put on the use of alkalies, but with no appreciable benefit. The difficulty seems to lie in our inability to exert a real local influence on the catarrh of the bile duct. To bring about that result I would recommend washing out his stomach systematically and regularly every morning, and, at the same time, giving him better food than he has been in the

habit of taking A change of climate would also be very beneficial in his case. There is one of the mineral waters which if taken in its native soil, viz.: Ems, in Germany, would prove of great benefit. If this patient were able to go there and take a systematic course of the waters of Ems, I have not the least doubt but that he would be very greatly benefited.

COMMUNICATIONS.

THE THERAPEUTIC USES OF KAVA-KAVA.

BY DAVID CERNA, M. D., PH. D.

ASSISTANT IN PHYSIOLOGY, UNIVERSITY OF PENNSYLVANIA.

Though not commonly employed at present by the profession, Kava-Kava has a domestic history suggestive of highly valuable clinical properties. This entitles the drug to serious consideration, and it seems that the results obtained by various observers in the treatment of a certain class of cases, warrant its further and continuous use in practical medicine.

In a previous experimental study,[1] I have discussed the general physiological action of this drug, and found that it powerfully affected the circulation, exercising at the same time a stimulating influence on the respiration and nervous system. The most important properties of the plant, from a practical point of view, were, perhaps, those exercised on the mucus membrane, the liver and the nervous system, the remedy being especially a general and local anæsthetic and a depressant of the spinal motor apparatus. These actions have been noticed also by previous observers.

In the present paper I will treat of the therapeutic uses of the drug, with special reference to the literature of the subject which, in itself, is interesting and instructive. I will in the first place detail the following cases in which gratifying results have been achieved. With a view to determine whether the effects produced would be attributed solely to the influence of the drug, no other treatment was applied in some of the cases observed.

Case I. Gonorrhœa, S. G., age 19, dental student, of bilious temperament, with good family and previous individual history. Contracted the disease four months ago. Was under treatment since the appearance of the first symptoms. Had taken copaiba and cubebs internally and for injections had used solutions of acetate of lead, sulphate of zinc and nitrate of silver. Very little relief was obtained; the painful micturition continued and the discharge, although not abundant, was yet a source of much annoyance and anxiety. Under my charge all other general and local treatment was put aside and the patient subjected to the use, internally, of the fluid extract of the Kava-Kava, fifteen drops three times a day. Amelioration was noticed in three days. In two weeks the patient was entirely well. The medicine was then suspended and no return of the disease occurred.

Case II. Gonorrhœa, J. L. F., 24 years of age, of nervous temperament, salesman by occupation, was suffering from a third attack of specific urethritis of a few days' standing. He said that the two previous attacks lasted for two and three months respectively, the disease having finally disappeared under general and local treatment and a rigorous diet. He complained of injections having been extremely painful. When the patient was first seen by me the discharge was abundant, and there was great pain in micturition. No stricture was detected, but there was undoubtedly a beginning inflammation of the bladder. He was immediately placed under Kava-Kava to the exclusion of all other remedies. Dose, twenty drops three times a day. Relief was experienced by the fourth day, with great lessening of the discharge and the burning pain on passing water. Improvement continued and at the end of the third week the patient considered himself entirely cured. There was no return of the malady for over two months after the suspension of the drug.

Case III. Chronic Gonorrhœa with Cystitis. M. A. C., medical student, age twenty-two, of a nervo-sanguine temperament, had for nearly two years suffered from an old case of specific urethritis complicated with cystitis, as a result of a third attack of the malady. The disease had never yielded to the usual remedies. A careful examination revealed no stricture, but the doubtless coexistence of prostatitis and a considerable cystitis. The discharge was scanty and muco-purulent, and although not always present there was, at times, great pain in micturition. The patient was advised to take Kava-Kava and to discontinue all other treatment. He began to take the drug immediately, and in comparatively large quantities—thirty to forty drops three times a day. In about two weeks great im-

[1] *The Therapeutic Gazette*, January 15, 1891.

provement was noticed. All burning sensations had entirely gone, although the discharge continued. This, however, diminished gradually, but did not entirely disappear after two months' treatment. It was noticed that the drug considerably increased the amount of urine. The remedy was afterwards combined with sweet spirits of nitre, and although there was no stricture, the passing into the urethra, twice daily, of a sound smeared with belladonna ointment, was recommended. In about four months the patient, though not entirely well, reported satisfactory progress. At present (eight months afterwards) he continues to take the remedy, with fair chances of complete recovery. The cystitis had disappeared and there was a notable reduction in the size of the prostate gland. It may be stated that this patient was somewhat careless about diet and regular habits, and this circumstance, I think, has delayed a final and more rapid cure. The drug has not been taken with regularity.

The following two cases were kindly communicated to me by a practitioner to whom I suggested the use of the remedy:

Case IV. A colored boy, eight years of age, had been troubled with painful and frequent micturition for over six months. Had been examined carefully for calculous deposits, but no stone was found in the bladder, nor were there noticed any traces of gravel. The urine was scanty in amount, presented a high specific gravity, 1030, and of a decidedly alkaline reaction, but no albumen or sugar was found in it. The microscope revealed triple phosphates and a considerable quantity of pus corpuscles. By exclusion the case was diagnosed as one of chronic cystitis, and accordingly subjected to the usual treatments. Benzoic acid, benzoate of sodium and eucalyptol were employed, but with negative results. No relief being obtained by these and other measures, the patient was put under the exclusive use of Kava-Kava, in ten drop doses, twice a day, with wonderful results in the course of two weeks. A cure was effected in one month. One of the actions of the drug in this case was the notable increase of the quantity of urine.

Case V. Vaginitis. A shop girl, twenty-two years of age, of a sanguine temperament, single, but who had evidently fallen from grace, presented all the symptoms of a typical vaginitis as a probable sequence of a previous attack of gonorrhœa. History imperfect but sufficiently clear. Said that she had been under treatment by regular physicians for a long time but had obtained no apparent relief. Had taken medicine and used various injections, but all to no avail. She was placed exclusively under the use of Kava-Kava in doses of twenty drops, three times a day. A change for the better was noticed in about three weeks, and the abundant and fetid discharge had lessened to about one-half its original amount. The treatment was continued, and in three months the patient pronounced herself perfectly well. The medicine was then suspended, and she was requested to report if the disease should return. The case was not heard of afterwards, and it is presumed that the trouble did not reappear.

Other cases may be cited, but the short number reported here, is sufficient, I think, to corroborate the results obtained by other practitioners, and to show that the drug possesses valuable therapeutic properties. Kava-Kava is unquestionably of great service, especially in the treatment of the various inflammations of the mucus membranes, its action in these instances being chiefly a local one. There is no doubt that the drug is also a general stimulant and tonic.

No deleterious after-effects have been observed under the therapeutic action of the drug, although in some cases it has been asserted to produce a slight constipation. It further stated[1] that when taken in excess as an intoxicating beverage it produces a peculiar skin eruption, known in Tahiti as *areverea;* and that, curiously enough, it has been used with success in erysipelatous eruptions.

In the cases above described, the preparation used was the fluid extract in doses of from ten to thirty drops, in water, three times a day. The drug has no disagreeable taste. Although other forms have been used by various observers, the fluid extract is the most reliable preparation. The remedy may be given by itself, or in combination with other drugs, such as sweet spirits of nitre, glycerine, iodide of potassium, etc., according to the indications of individual cases.

Kava-Kava is not a new therapeutic agent. Its value in the treatment of disease has long been recognized by reliable practitioners.

It was first recommended in gonorrhœa as far back as 1857[2] and we are told that in Nukahibi the natives use Kava-Kava, in small doses and at bed time, in the treatment of bronchitis and phthisis; and even

[1] *Pharmaceutial Journal, IX*, p. 218.

[2] *Annal. de Therapeutic*, 1857, p. 61.

in gout, it has been recommended internally and as a local application[1].

An interesting physiological and therapeutical study of the drug was made several years ago by Dupuy[2] who found that the plant was a sialagogue and that it acted upon the stomach as a bitter tonic, improving the appetite without producing diarrhœa or constipation, and acting perhaps as a prophylactic to catarrhal affections of the upper part of the digestive canal; that it was a gentle excitant of the central nervous system, a powerful diuretic and an excellent blennostatic. The same author found the resin of Kava-Kava to be exceedingly valuable in the treatment of acute urethritis and vaginitis, relieving pain and diminishing the secretion.

Leighton Kesteren[3] asserts that the most marked and valuable property of Kava is its action upon the genito-urinary tract. He found that the drug readily cured chronic gonorrhœal gleet, and that in chronic cystitis it possessed an influence superior to any other remedy he had ever used.

It has been prescribed with flattering success, by Edward Miller[4] in suppurative urethral inflammation. Four cases of cystitis have been cured by the same author.

The best results in the treatment of acute and chronic gonorrhœa have been obtained by C. C. Switzer[5] and J. P. Siddall.[6] The latter writer affirms to have cured also several cases of leucorrhœa, where other remedies had entirely failed.

A case of secondary gonorrhœal inflammation and four cases of acute and chronic cystitis were cured by Kava-Kava after other remedies had failed, according to the report of R. A. French.[7] The same results were observed by J. P. Baird[8] in a case of rebellious urethritis, and in one of prostatitis, accompanied with painful urination.

In cases of painful micturition, from whatever cause, no remedy has given better results in the hands of W. J. Holman.[9]

The most excellent results have also been produced by the drug, in the treatment of acute and chronic gonorrhœa, according to the reports of Boardman Reed,[1] W. Semple,[2] J. M. Blackberry,[3] and of the Charity Hospital of New York City.[4]

Another observer states that the plant produces a primary stimulating effect, increasing the secretion of the mucus membranes, afterwards acting as a tonic, improving the appetite and giving tone to the digestive organs, and in this respect, acting differently from copaiba and cubebs. This has been the experience of Alfred Fliesburg,[5] who has successfully treated with the drug, cases of cystitis and urethritis. He further asserts to have obtained excellent results in over a hundred cases of acute, sub-acute and chronic bronchitis.

Six cases of stubborn nocturnal incontinence of urine, where even belladonna failed to produce any relief, were cured with Kava-Kava, by C. N. Palmer.[6] In dropsy it has been employed with success by Herbert C. Rogers.[7] According to Weinstein[8] the good effects of the drug in cases of emphysema and tuberculosis were manifested against the dyspnœa. The same author found it valuable in acute polyarthritis, gonorrhœa, and catarrh of the bladder, where the remedy seemed to act as an analgesic. In small doses it was employed with success in acute and chronic catarrh of the stomach, in dyspepsia and cardialgia.

In carefully looking over the records of cases published, I have been able to collect a considerable number of well authenticated instances, where not only improvement, but a permanent benefit has been produced. I subjoin the following tables in the hope that they may be of some use to those interested in the subject. In these tables, among other features treated, statements are briefly made especially in regard to the affections for which Kava-Kava has been employed, together with the results obtained.

I do not pretend to have exhausted the literature of the subject, but I have not, so far, been able to find any other reports than those referred to in this article.

TABLES OF CASES TREATED BY KAVA-KAVA WITH THE RESULTS OBTAINED.

No.	Age.	Sex.	Dosage and Preparation Used.	Disease.	Duration of Treatment.	Result.	By Whom and Where Reported.	Remarks.
1	(?)	(?)	(?)	Cystitis.	(?)	Recovery.	Miller, Edward.—*Therapeutic Gazette*, April, 1880.	
2	(?)	(?)	(?)	Cystitis.	(?)	Recovery.	Miller, Edward.—*Ibid.*	
3	(?)	(?)	(?)	Cystitis.	(?)	Recovery.	Miller, Edward.—*Ibid.*	
4	(?)	(?)	(?)	Cystitis.	(?)	Recovery.	Miller, Edward.—*Ibid.*	
5	(?)	(?)	Fluid extract, dosage not stated.	Cystitis.	(?)	Recovery.	French, R. A.—*New Preparations*, July, 1879.	
6	(?)	(?)	Fluid extract, dosage not stated.	Cystitis.	(?)	Recovery.	French, R. A.—*Ibid.*	
7	(?)	(?)	Fluid extract, dosage not stated.	Cystitis.	(?)	Recovery.	French, R. A.—*Ibid.*	
8	(?)	(?)	Fluid extract, 15 drops, 3 times a day.	Chronic Cystitis.	(?)	Recovery.	French, R. A.—*Ibid.*	
9	(?)	M.	Fluid extract, teaspoonful 3 times a day.	Gonorrhœa.	(?)	Recovery.	Baird, J. P.—*Therapeutic Gazette*, May, 1880.	
10	(?)	M.	Fluid extract, teaspoonful 3 times a day.	Prostatorrhœa.	(?)	Recovery.	Baird, J. P.—*Ibid.*	
11	6 yrs.	M.	Fluid extract, 8 drops every 3 hours.	Cystitis.	4 days.	Recovery.	Holman, W. J.—*Medical and Surgical Reporter*, Sept. 25, 1880.	
12	50 yrs.	M.	Fluid extract, 25 drops 4 times a day.	Cystitis.	(?)	Recovery.	Holman, W. J.—*Ibid.*	Patient had chills and fever. Paroxysms of pain continued between chills.
13	23 yrs.	F.	Fluid extract, 15 drops 3 times a day.	Chronic Cystitis.	(?)	Recovery.	Holman, W. J.—*Ibid.*	
14	78 yrs.	M.	Fluid extract, 25 drops every 2 hours.	Retention of urine.	12 hours.	Recovery.	Holman, W. J.—*Ibid.*	
15	21 yrs.	M.	Fluid extract, 20 drops 3 times a day.	Gonorrhœa.	6 days.	Recovery.	Holman, W. J.—*Ibid.*	

No.	Age.	Sex.	Dosage and Preparation Used.	Disease.	Duration of Treatment.	Result.	By Whom and Where Reported.	Remarks.
16	(?)	M.	Fluid extract, 15 drops, 3 times a day.	Gonorrhœa.	3 days.	Recovery.	Reed, Boardman.—*Therapeutic Gazette*, Feb'y. 1882.	
17	(?)	M.	Fluid extract, 15 drops, 3 times a day.	Gonorrhœa.	8 days.	Recovery.	Reed, Boardman.—*Ibid.*	
18	27 yrs.	M.	Fluid extract, combined with sweet spirits nitre.	Gleet.	(?)	Recovery.	Blackberry, J. M.— *Therapeutic Gazette*, May, 1881.	
19	23 yrs.	M.	Fluid extract combined with fluid extract of Berberis.	Gleet.	6 weeks.	Recovery.	Blackberry, J. M.—*Ibid.*	
20	(?)	(?)	Fluid extract, dosage not stated.	Gonorrhœa.	(?)	Relieved.	Charity Hospital, N. Y. City. *Therapeutic Gazette*, June, 1881.	
21	(?)	(?)	Fluid extract, dosage not stated.	Gonorrhœa.	(?)	Relieved.	Charity Hospital, N. Y. City. —*Ibid.*	
22	(?)	(?)	Fluid extract, dosage not stated.	Gonorrhœa.	(?)	Relieved.	Charity Hospital, N. Y. City. —*Ibid.*	
23	(?)	(?)	Fluid Extract, dosage not stated.	Gonorrhœa.	(?)	Relieved.	Charity Hospital, N. Y.City. —*Ibid.*	
24	24 yrs.	M.	Fluid extract, combined with fluid extract, Yerba Santa.	Gleet.	(?)	Recovery.	Fliesburg, Alfred. — *Therapeutic Gazette*, April, 1883.	
25	35 yrs.	F.	Fluid extract, combined with buchu & eucalyptus.	Urethritis with cystitis.	(?)	Recovery.	Fliesburg, Alfred.—*Ibid.*	
26	50 yrs.	M.	Fluid extract, combined with buchu & eucalyptus.	Cystitis with prostatitis.	(?)	Relieved.	Fliesburg, Albert.—*Ibid.*	
27	(?)	(?)	Fluid extract, dosage not stated.	Incontinence of urine.	(?)	Recovery.	Palmer, C. N.—*Therapeutic Gazette*, Aug., 1883.	
28	(?)	(?)	Fluid extract, dosage not stated.	Incontinence of urine.	(?)	Recovery.	Palmer, C. N.—*Ibid.*	
29	(?)	(?)	Fluid extract, dosage not stated.	Incontinence of urine.	(?)	Recovery.	Palmer, C. N.—*Ibid.*	

No.	Age.	Sex.	Dosage and Preparation Used.	Disease.	Duration of Treatment.	Result.	By whom and Where Reported.	Remarks.
30	(?)	(?)	Fluid extract, dosage not stated.	Incontinence of urine.	(?)	Recovery.	Palmer, C. N.—*Ibid.*	
31	(?)	(?)	Fluid extract, dosage not stated.	Incontinence of urine.	(?)	Recovery.	Palmer, C. N.—*Ibid.*	
32	(?)	(?)	Fluid extract, dosage not stated.	Incontinence of urine.	(?)	Recovery.	Palmer, C. N.—*Ibid.*	
33	27 yrs.	M.	Fluid extract, 30 minims every 3 hours.	Dropsy.	3 months.	Recovery.	Rogers, Herbert C.—*Med. News*, Oct. 16, 1886.	
34	35 yrs.	F.	Fluid extract, 40 minims every 4 hours.	Dropsy.	2 months.	Relieved.	Rogers, Herbert C.—*Ibid.*	Patient had suffered from scarlet fever, when 17 years of age.
35	31 yrs.	M.	Fluid extract, combined, with convallaria, 5 minims 3 times a day.	Dropsy.	2 months.	Relieved.	Rogers, Herbert C.—*Ibid.*	Disease evidently due to cardiac disorder.
36	16 yrs.	F.	Fluid extract, 40 drops every 3 hours, with tincture of the chloride of iron.	Dropsy.	A few weeks.	Recovery.	Rogers, Herbert C.—*Ibid.*	Patient had had scarlet fever 3 or 4 weeks previously.
37	19 yrs.	M	Fluid extract, 15 drops 3 times a day.	Gonorrhœa.	2 weeks.	Recovery.	Author.	
38	24 yrs.	M.	Fluid extract, 20 drops 3 times a day.	Gonorrhœa.	3 weeks.	Recovery.	Author.	
39	22 yrs.	M.	Fluid extract 30 to 40 drops 3 times a day, in combination with sweet spirits of nitre.	Gleet with cystitis.	8 months.	Relieved.	Author.	Patient of irregular, or perhaps better careless habits. Medicine had not been been taken with regularity.
40	8 yrs.	M.	Fluid extract, 10 drops, 3 times a day.	Chronic cystitis.	1 month.	Recovery.	Author.	
41	22 yrs.	F.	Fluid extract, 20 drops, 3 three times a day.	Vaginitis.	3 months.	Recovery.	Author.	

To recapitulate, of the authenticated cases treated with Kava-Kava, as reported in this paper, there were:

Relieved—Gonorrhœa, 4; Cystitis, 1; Dropsy, 2; Gleet, 1; in all 8 cases.

Cured—Acute Cystitis, 9; Chronic Cystitis, 2; Gonorrhœa, 6; Prostatorrhœa, 1; Retention of Urine, 1; Gleet, 4; Urethritis, with Cystitis, 1; Incontinence, of urine, 6; Dropsy, 2; Vaginitis, 1; in all 33 cases.

Total forty-one cases.

It is thus seen that Kava-Kava, from these statistics, is a therapeutic agent of no inferior value, and worthy of further consideration. Certainly it does not deserve the neglect in which the remedy is at present held by the medical profession.

THE EXPECTANT TREATMENT IN CASES OF SUSPECTED SYPHYLITIC INFECTION.

BY HENRY BEATES, Jr., M.D.,

PHILADELPHIA.

Bassereau, father of the Dualist School, wrote:

(1.) "If a person who has been affected with chancres, followed by constitutional symptoms, is confronted with the person who gave the infection, or with those to whom it has been communicated, it will be found that all such, without exception, have been affected with chancres followed by constitutional manifestations. The chancre is never purely local.

(2). "On the other hand, if one who is affected with a chancre which has not been followed by any syphilitic symptom, be confronted by the person who has caused the infection, the former will be found to be the bearer of a chancre which is entirely local and which does not infect the constitution. This admits of no exceptions.

"Thus no chancre which is followed by constitutional symptoms gives rise to a purely local sore, nor does a local chancre by infection communicate an ulcer which is capable of producing syphilis."

These cardinal truths, when first proclaimed, enabled clinical distinctions to be made between the non-syphilitic lesion and true chancre, and upon the ability to recognize these respective lesions will treatment be largely determined.

When the clinical characteristics of initial lesions are typically pronounced, prognosis and treatment are self-evident, but, unfortunately, like typhoid fever, and, indeed, all diseases, the departures are often so great that it is frequently absolutely impossible to diagnosticate the lesion, and here it is that we hesitate how to act. To illustrate: A patient two or three days after a suspicious confrontation suffers from a multiple ulcerative lesion. The time of development, character of abrasion, and clinical history, incline to the belief that we have before us a chancroid. The sores are cauterized the patient is told that he is free from syphilis and is dismissed with the belief that he is suffering from a simple ulceration, which, in ten days will have healed and not be followed by constitutional trouble. In six weeks this individual probably returns because of a cold and an eruption which are recognized as the secondary phenomena of syphilis. The practitioner consults works of reference and consoles his mind with reading about a mixed sore, and pacifies the unfortunate syphilitic, and fortifies himself against criticism, by showing the victim the paragraph which affords such abundant diagnostic latitude. Without further discussion of this *ignis fatuus*—the mixed chancre—it is self-evident that a true description of it is, a venereal ulcer, the character of which can not be ascertained; if followed by syphilis (and a favorable prognosis had been given), "it was mixed," if not, "it was no chancre at all," but what we believe all chancroids are: *Simple venereal ulcers.*

It may not be amiss here to describe the sores which are not followed by syphilis and those which are. I will use term simple venereal ulcer for chancroid, and chancre for the specific, hard, or Hunterian lesion.

SIMPLE VENEREAL ULCER.

1. No period of incubation.
2. Originates from similar lesion or pus from bubo.
3. Multiple and confluent.
4. Auto-inoculable.
5. Begins as a vesico-pustule.
6. The lesion is an ulcer, deep, with sharply cut perpendicular walls or undermined, purulent base and secretion, and painful.
7. The hardness is around the lesion and is simply tissue infiltrated with inflammatory lymph.
8. The lymphatic glands are frequently inflamed, painful and possess a suppurative tendency. Bubo common.
9. Tendency to progressive ulceration and invasion of structure.

CHANCRE.

1. Period of incubation 10–35 days.
2. Originates from chancre or secretion of secondary stages like mucus, saliva, or blood.
3. Single, perhaps never confluent, and rarely multiple.
4. Not auto-inoculable.
5. Is a simple erosion or a papule.
6. Lesion is saucer-shaped or hollowed out, superficial, almost clean base, very little if any secretion, and very little pus.
7. The hardness is limited to the lesion and is minute in size and suggestive of a small shot.
8. Lymphatic glands indurated, not very painful and free from active inflammatory processes.
9. Chancre is locally a lesion of little suffering and tends to spontaneously heal without treatment.

These characteristics, then, when typically present, offer no difficulty, but when exceptions rule what is to be done? Prominent schools advise absolutely opposite lines of procedure. One teaches that the immediate exhibition of antisyphilitics is a *sine qua non*, and any other plan unwarranted; the other promulgates the doctrine that to treat a patient with a doubtful lesion in any but an expectant plan is wrong. In the confused light we have of the course of syphilis this possesses much to recommend it.

What is the natural history, so to speak, of syphilis? A fact to which little attention seems to have been directed is, that in many instances, just as in any disease, cure occurs spontaneously. This is to be remembered. Again it is a prevalent belief that mercury possesses the power to modify or even prevent the appearance of secondary phenomena, and, consequently, the so-called tertiary sequela are also averted. In strong contrast with this exists the indisputable fact that very frequently while a patient with chancre is taking mercury secondary phenomena occur. It is true sometimes a little late. A sect of syphilographers teaches that mercury aggravates the after developments and imperatively demands the utter abandonment of the drug. Another sect holds a contrary opinion. How is this prominent face-to-face contradiction of therapeutics explained? If the method of treatment be examined the answer is contained in this statement of Zeissl: "It is true if an individual suffering from an early syphilitic eruption is subjected at once to mercurial treatment, the symptoms existing at the time usually disappear very rapidly, but the syphilitic diathesis remains, and is manifested particularly by hyperplastic lymphatic glands." It will be noticed, however, that among one hundred individuals treated in this way 96 on the average will be attacked by relapses sooner or later. In those individuals who have received mercurials internally or hypodermically at the first appearance of a syphilitic eruption, the relapses occur as often as after early inunctions. Opaline patches on the mucous membrane of the tongue, mouth and pharynx, occur with special frequency after the internal or hypodermic administration of corrosive sublimate.

If we make a résumé of these facts, it appears that mercury when given in the earliest phases of syphilis, causes a very rapid disappearance of the morbid symptoms, but that relapses occur more frequently than after other methods. I would also call attention to this: "The favorable results which may be attributed to mercury, are, that it usually causes more rapid disappearance of the symptoms of syphilis than other specifics, and that, when it is used two or three months after infection, and the disease has had time to exhaust itself somewhat, very small doses suffice to cause the disappearance of the symptoms." As a matter of course, it cannot be foretold whether such recovery is permanent. But we must ask, in the light of the knowledge we possess of the natural course of syphilis, whether two or three months' exhibition of mercury is the kind of therapeutics upon which it is proper to base or formulate a principle? It seems that no argument is demanded. So much for the anti-mercurialists.

A few words in conclusion regarding the diagnosis of the initial lesion. It is evident that we have to deal with two, and only two, lesions in our diagnosis. When the above characteristics of chancre are typically developed there is no difficulty, and we cannot be in doubt as to the proper treatment. I believe in the cauterization of chancre for self-evident reasons. It satisfies the patient and reduces the chances of further infection and enables a line of treatment to be described. As mercury in my opinion is, as a rule, the specific to be employed, and as this remedy does not invariably prevent the manifestations of secondary phenomena, and as in many instances the diagnosis of the initial lesion is obscure, it is a rule with me to not administer the drug until constitutional manifestations occur. By this plan the condition of the patient is not permitted

to be worse than it would be, if mercury be given immediately. I refer here to cases where the diagnosis is certain, for where there is doubt there should never be instituted specific treatment. Again, where diagnosis is certain, the clinical fact that secondary phenomena are an index of the future course of the disease, and that mercury modifies, while it does not prevent these, it is just as imperative to know the type with which we are to deal as it is to know the type of pneumonia or typhoid fever. This is the more important as the treatment is entirely too routine; so much so that it can be said with a great degree of truth that the treatment of syphilis is the exhibition of a standard mixture of iodide of potassium and bichloride of mercury or one-fourth to one-half grain doses of iodide of mercury, no matter what the mildness or severity of phenomena may be, or structures involved. It is just as reasonable to institute the most active measures in vogue for any disease because an initial sign or symptom was present as to blindly exhibit mercury in case of chancre. Who would introduce a Dwyer tube or perform a tracheotomy upon the earliest manifestation of a diphtheria? Is the one more inconsistent than the other?

What are some of the advantages gained by waiting until secondaries occur? First, we have some chancres not followed by constitutional phenomena at all; just as some people experience a sore throat in a scarlatinous room yet enjoy immunity from constitutional involvement. Second, a rash occurring within seven weeks indicates severity and places the physician on guard. Third, the rash occurring on time, its profuseness and type indicate a greater or lesser dyscrasia or tertiary future, and in my experience demonstrates the necessity of early instituting those remedies which we usually employ in the tertiary stage. Fourth, a late appearing rash is indicative of a mild after-course, this, like the preceding, being greater or less according to profuseness and type.

LETTERS FROM SPECIAL CORRESPONDENTS.

Paris Letter.

SURGICAL INTERVENTION IN DISEASES OF THE NERVE-CENTERS.

Paris, April 10th, 1891.

The Fifth French Congress of Surgery has just completed its work. It was held in Paris between March 30 and April 4, a great many eminent surgeons from every country being present.

The first question which had been given out last year as a subject for discussion was on "Surgical Intervention in Diseases of the Nerve-Centers."

Prof. V. Horsley, from London, who is well known to the medical profession for his works in that line, was to open the discussion, but, at the last moment, he was kept away and had his paper read by his assistant, Dr. Boyce. The principle part of the paper referred to the surgical method used, which consisted of opening the cranium by means of a very large trephine; the cutaneous flap is very large; and, the opening in the bone is also made large. The way in which the cranial section is made is as follows: A trephine is applied until it reaches to about the middle of the depth of the portion of bone to be removed; and from the center of this portion a smaller disk of bone is removed, the remaining bone up to the limit indicated by the first cut is removed with bone forceps.

When the convulsions are limited to a certain portion of the body, it is comparatively easy to localize the seat of the trouble and the part where we are to interfere. If, however, this is not ascertained accurately, when the brain is exposed in the suspected region, the exact part may be found by the application of an electric current.

As regards the medical treatment of cortical tumors, Dr. Horsley says that one ought never to use specific treatment longer than six weeks; if, after such a time, the case does not improve, it is a clear case for operation; for even after a simple exploratory trephining, the cessation of the cerebral compression may be enough to effect a cure, as has been observed in several cases.

Prof. Lannelongue, of Paris, read a paper on the "Treatment of Microcephalous by Craniectomy," he gave the result of 25 operations performed by himself. He called attention, first, to the fact, that in microcephalous patients, one finds an advanced state of the union of the sutures and narrowness of the fontanelles. In microcephalic patients ossification of the fontanelles is anticipated. The affections which can be benefited by craniectomy, according to Dr. Lannelongue, are numerous. Obstetrical compression, in hæmatoma, circumscribed pachymeninigitis, serous cysts, etc., in hydrocephalous hyperostosis of hereditary syphilitic origin—again, in diseases of the brain-sub-

stance itself, in cerebral atrophy of vascular origin, in diffuse sclerosis, etc.

Two kinds of operations are recommended by the author: 1st, linear craniectomy; 2d, flap craniectomy.

The first one is made along the superior longitudinal sinus and can be extended through the coronal suture, on the motor or Rolandic zone, towards Broca's center; he has also practiced it on the occipital behind, between the lateral sinus and the occipito-parietal suture; again, he has performed a transversal and symmetrical craniectomy on the frontal bone by detaching the longitudinal sinus.

By flap craniectomy, he means that operation which consists in making sections of the cranium combined so as to allow the flaps to remain adherent by a more or less extensive bony base. Sometimes the flap involves only one bone—the frontal, or the parietal; more often it extends over two bones—the frontal and parietal. The gap between the cut surfaces varies from 8 to 12 millimeters. The operation is performed by attacking the bone with a trephine, at one of the extremities of the wound, and then doing the rest with cutting forceps. The dura mater can be left untouched; if, however, there exists any trace of pachymeningitis, it would be well to puncture it or even to open it freely; if, however, an incision has been made in the dura mater, this membrane must be sutured, which is not necessary if only punctures have been made. As to the periosteum, it can be excised or not; both have been done, with no advantage one over the other. As to the final results—out of 25 craniectomies, he has had one death in 48 hours from acute septicæmia and continuous flowing of the cerebro-spinal fluid. The youngest child operated on was 8 months old, and the oldest 12½ years—as to the after-results, they were all benefited by the operation.

Dr. Anger, of Paris, also reported a case of craniectomy which was performed on a child 8 years old, who was taken, when 15 months old, with severe convulsions, occurring in the evening, and her intelligence seemed to cease developing. In fact she was at the time of the operation, so far as intelligence was concerned as little advanced as any 15 months child and did not even know her alphabet; she repeated words without understanding them; she said papa and mamma; she had no idea of danger and had several times fallen out of a window. The operation was made as follows: A linear incision was carried from the frontal eminence to the lambdoid suture; a first disk of bone was removed, and the cranial excision was then continued for 12 centimeters (4 inches); the dura mater being prominent, a puncture was made with a hypodermic needle. The osseous wound was then enlarged, and when finished had an oval form of 11½ centimeters long (4 inches) antero-posteriorly, and 4 centimeters (1½ inch) transversely. The skin was finally united.

The day following the operation, the patient ceased to urinate or defecate in bed; she asked to eat; she began to cry when any one spoke of her absent parents; the athetose movements which existed ceased; and, finally, she has been improving steadily, both physically and intellectually up to date.

Dr. Girard presented an interesting case of Essential or Idiopathic Epilepsy, cured by trephining. The patient, aged 29, had been suffering from epileptic fits, five or six a day, ever since the age of 14. At 29, in a fit of anger, she shot herself in the right temple, and fell in a state of coma; the left arm was completely paralyzed. She was trephined, several pieces of bone and the bullet were removed and the skin again closed. It is now five months since the operation, and the patient has not had a single fit. She had before her operation six children, five of them having died from convulsions.

Dr. Duret, from Lille, also presented two cases of trephining. One was for aphasia of traumatic origin, the patient having fallen on his head. On trephining, a large clot was found in the Rolandic region, and removed; the patient was soon able to speak again, but unfortunately on the 23d day after the operation, after a rather copious alcoholic dissipation, he was attacked by severe cerebral congestion, with convulsions of the four extremities, from which he never recovered.

The second case was that of a young soldier of 22, who had had a fall at 14, and was subject to epilepsy. Trephining exposed a diseased arachnoid membrane in the parietal region. The epileptiform attacks, the headache, and vertigo ceased after this operation.

Dr. Jeannel, from Toulouse, reported a case of trephining for Jacksonian epilepsy. The patient had suddenly been seized a year ago, by an attack of apoplexy which left behind it a palsy of the right upper extremity. Two months later he had another attack, followed by spasmodic move-

ments of the right upper extremity; sometimes these would extend to the face and to the lower extremity, but still there was a continuous spasmodic agitation of the right forearm. There was also more or less complete aphasia. On the left side of the cranium no depression could be found. A small cicatrix existed, however, which was the result of a punctured wound made at the age of 15, but the cicatrix was not adherent. The cranium was opened in the Rolandic region on that side. When opened Dr. Jeannel found a violet, flabby mass which was firmly united with the cerebral substance, and extended downwards and backwards, so that the bony opening had to be enlarged. This diseased mass was curetted out and a hole, the size of a green almond, was left in the cerebral substance. The periosteum and skin were then united.

The day following the operation, all spasmotic movements had disappeared, but were replaced by a paralysis of the right forearm; the speech returned very slowly; no more epileptic fits occurred.

Dr. Regnier, of Paris, presented also a case of trephining for Jacksonian epilepsy. The case is an interesting one, as Prof. Charcot had given the following diagnosis: Partial sensitive-motor epilepsy, corresponding to a probable lesion at the middle and inferior regions of the Rolandic convolutions.

At the age of 5, the patient had been taken with a sensation of pricking on all the mucus membranes of her head and an abundant lachrymal secretion. In 1888, she fell several times on her head, and one finds to-day a cicatrix in the left parietal region. In April, 1889, she had her first attack; her mouth was strongly twisted to the right four or five times a day. Convulsions extended to the head more than to the arms and lower extremities.

The operation of trephining was resorted to. A disk was removed from over the Rolandic region and the opening enlarged, when the surgeon found a gray-colored tumor, of cystic appearance, extending down into the cerebral substance. This extended further forward than the margin of the bony section, so that after having scraped out as much as possible of its superficial portion, the wound was closed. The fits, however, returned again, so that a new operation had to be performed 4 months later. It was then found that the tumor had already re-formed itself, and it was again enucleated with the curette; the tumor was a glioma with a central cystic cavity, and it was situated at the inferior extremity of the ascending frontal convolution and the lower end of the third frontal convolution.

Dr. Michaux, of Paris, presented a case of trephining for non-traumatic meningeal hemorrhage. The patient was an habitual absinthe drinker and had been so for years. He was brought to the hospital in a complete state of apoplexy, with left facial palsy and paralysis of the right upper extremity. The following days the paralysis extended to the right inferior extremity; epileptiform convulsions occurred, etc. In addition, the patient did not present the least sign of external traumatism.

The patient was trephined over the Rolandic region on the left side; three disks of bone were removed, making an opening of 2 inches long. The dura mater was next incised and this allowed several large black clots to escape—the quantity of two table-spoonfuls. The symptoms gradually disappeared, excepting those connected with speech, which has remained slightly defective even five months after the operation.

This was a clear case of spontaneous hemorrhage of alcoholic or uræmic origin cured by trephining.

Dr. Picqué, of Paris, reported another case of trephining. It was in a young lady, aged 19, who shot herself with a revolver. She was in a comatose state for five days and then gradually and completely recovered her mental faculties. The attending physician said there was no penetration, yet there was a wound at a point between the right frontal region and the corresponding temporal, a little in front of the coronal suture. The patient complaining of persistent headache on the right side, the diagnosis of cerebral abscess was made, hence trephining was resorted to. The cerebral surface appeared intact, except at one part, where the gray substance protruded. An incision brought out a great deal of pus, but the bullet could not be found. To-day the patient has completely recovered and is doing very well.

Dr. Broca, from Paris, presented three cases. On one of his patients, there was an indication of localization: an athetose movement of the upper extremity; yet in that case the author concluded at once that the cortical center of the upper extremity ought to be exposed, for according to the history of the disease and the form of the head of the patient, he has diagnosticated intra-ventricular hydrocephalus, hence the first surgical indication was the removal of part of this liquid, so as to diminish the compression of the brain. He, therefore,

opened and drained the left lateral ventricle, using Keen's process of trephining one inch behind and above the external auditory meatus.

His second case was an infantile spasmodic brachial monoplegia. The athetose contractions of the left upper extremity resembled the preceding patient's condition, but the history of the disease, as well as the form of the head, pointed to infantile cerebral sclerosis. In addition, for the past four years, the patient had had fits of Jacksonian epilepsy starting from the thumb.

On trephining, a cyst was found on the motor center for the thumb, at the postero-inferior portion of the center of the upper extremity. The epileptic fits have not completely ceased.

Finally, the third case was one of compound fracture, for which the patient had already been trephined and a small abscess found; the operative result was good, but a few months later the patient returned with a Jacksonian epilepsy of the lower maxilla and left upper extremity, presenting a small cranial fistula. Thinking that a small piece of bone might be the source of irritation, this was removed, with great improvement in the patient's condition.

Prof. Verneuil, of Paris, made an interesting communication on a case of "Fistula of the Sacral Region with escape of Cerebro-spinal Fluid." The young lady had noticed sixteen months before she presented herself at Dr. Verneuil's consultation, that a small tumor appeared in the sacral region, about the size of a small orange, which tumor burst spontaneously four months later, allowing a great quantity of pus to escape. Dr. Verneuil thinking that a sequestrum was the cause of the suppuration, operated with the thermo-cautery, but when he reached the supposed diseased bone, he found that his finger came in contact with one of the posterior sacral foramina, the borders of which appearing roughened were thoroughly scraped. The day after the operation the patient was found drenched in her dressings, this liquid examined and demonstrated to be cerebro-spinal fluid. Four days after the operation and this over-flowing, the patient was found in a state of deep coma and dyspnœa, but without fever or vomiting. These comatose states had occurred before whenever the abscess opened. The patient is to-day cured. The lesion was of bony origin, producing acute abscess, the dura mater having been perforated in one of the sacral foramina, from which occurred the escape of the arachnoid fluid.

Dr. Bazy, of Paris, also made a communication on exploratory surgical interference in cases of compression of the spinal cord, or in cases of uncertain diagnosis. He reported the case of a woman on whom he operated for symptoms which were ascribed to a probable tumor of the cord; the spinal canal was opened in the ruptured region, but with negative results; the wound healed without the least trouble. A. C. H.

Society Reports.

GYNECOLOGICAL AND OBSTETRICAL SOCIETY OF BALTIMORE.

Dr. Neale reported the following case of

"Occlusion of the Os Uteri during Four Days' Parturition:"

Mrs. K. W., æt. 26 years; white. Past history unimportant. Last menstruation early part of April, 1890. Pregnancy normal up to Nov. 16th, 1890, when she slipped and fell violently on her right side on the sidewalk. There was no vaginal discharge at the time and no discomfort except from the jar, bruising, etc., and the patient was up and about all the time. No movements of the child were felt after the fall.

About Christmas, 1890, an offensive yellowish vaginal (uterine) discharge occurred and continued for one week.

On the night of January 12th, 1891, her first labor pains began, and were so severe as to require morphine being given by her attendant. There was no "show" or discharge of any kind. The pains increased and the patient was suffering severely when I saw her for the first time, Friday evening, January 16th, 1891. She was a large well-built and well-nourished woman.

I could not distinctly map out the child by abdominal palpation. By auscultation gurgling was detected over the entire uterine tumor, but not a trace of fœtal heart sounds could be heard.

By vaginal examination; the vagina was very short and small, there was no cervix and no os. A continuous layer of mucus membrane, flush with the vaginal walls, closed over the entire vault of the vagina, and a little dimple in its center was the only indication of where the os ought to be.

The patient was chloroformed, placed in position, the hand passed into vagina, the finger pressed firmly against the dimple when it suddenly yielded or burst open like a membranous web, permitting a gush of a

not foul smelling bloody water to escape, and at once the rapidly enlarging outlines of the os could be felt, then about as wide as a silver half-dollar piece. The soft bagging scalp and loose cranial bones came down upon the enlarging os and as the expulsive efforts were almost *nil*, I grasped the head with a Simpson's cranioclast which tore away, and then adjusted the blades of a Tarnier basiotribe over the head and neck and a thoroughly macerated, but not decomposed or foul, small child was easily extracted. The perineum was intact, and the os fissured slightly. A small placenta appeared within six minutes. There was considerable post-partum hemorrhage, the uterus acting feebly. The os remained open about size of silver-half dollar piece, with thick edges; the uterus was rather small but not firmly contracted. Two quarts of a hot intra-uterine 1-4000 bichloride douche were injected. The patient rallied well and debarring an occasional slight rise of pulse and temperature, and faintly fœtid lochia which readily yielded to the antiseptic douche, the puerperum was uneventful and recovery complete. This case was a novel one to me. I am quite sure the membrane I felt was mucus, and not the amniotic sac, nor do I think the case should be classed among those of cervical occlusions or stenosis from endotrachelitis.

Dr. J. Whitridge Williams read a paper on

"THE INDUCTION OF PREMATURE LABOR IN CONTRACTED PELVES."

He pointed out that the comparative neglect of the operation in this country was due to two causes; the absence of large lying-in institutions and the consequent lack of large amounts of clinical material, and the almost total neglect of pelvic measurement.

By the term induction of premature labor, one understands the artificial interruption of pregnancy at such a period that a viable child may be born; that is, at any period from the 28th or 30th week to the end of pregnancy.

Dr. W. after a discourse on the history of the operation, showed that it was first rationally employed for this indication in England, as the result of a conference of the eminent physicians of London in the year 1756. Within fifty years it was quite generally employed on the Continent, and soon enjoyed a popularity which caused it to be resorted to on the most trifling pretexts, and which in 1869 called forth Spiegelberg's forcible denunciation of the operation by which he showed that the mortality, both of the mother and children, was nearly three times greater after the operation than if the woman went on to term.

This was soon followed by articles by Litzmann and Dohrn, who showed that Spiegelberg had painted the picture in colors far too dark. Litzmann showed that in moderate degrees of contraction, 8.25-7.5 cm. (3¼-3in.) the operation was indicated in the interests of the mother, as shown by a mortality of 7.4 per cent. after the operation compared with one of 18.7 per cent. when the woman was allowed to go on to term. Dohrn stated that the proper method of appreciating what the operation accomplished, was not to compare so many cases of induced labor with so many cases of labor at term, but to compare the results of premature and spontaneous labors in the same woman; by this method he found that twice as many children were saved by inducing labor as by allowing the woman to go on to term. Consequently, they proved that the operation was indicated in properly selected cases both in the interests of the mother and child. The introduction of antiseptic methods into midwifery, almost completely robbed the operation of danger for the mother, as will be readily seen from the following statistics. Thus Haidlen reports forty-four cases from the Stuttgart clinic, with no material deaths and 72 per cent. of the children saved. In 1889 Korn stated that Leopold lost one woman in forty-five cases and saved 66 per cent. of the children, and last July Ahlfeld stated that he had induced labor one hundred and eighteen times with the loss of only one mother, and had saved 62 per cent. of the children. At the Berlin Congress, Fehling stated that in sixty cases he had saved all the mothers and 80 per cent. of the children.

From the above sketch we will readily see that the maternal mortality in properly selected cases is very slight. Four hundred and one cases collected by Korn, showing a maternal mortality of only 2.9 per cent., or just a trifle more than normal labor in a normal pelvis, while the fœtal mortality ranges from 20 to 70 per cent., the average being about 33⅓ per cent. So in this operation we have a means of saving about two-thirds of the children without any risk of the mother. On reckoning by Dohrn's method we save at least twice as many children as if we allowed the woman to go on to

term, and then resorted to some conservative operation.

These are the prospects of the operation, but unfortunately the degree of contraction within which the operation is justifiable is very limited, and one can only think of it in moderate degrees of contraction. According to Litzmann, in flattened pelves with a conjugata vera of 6.5–8.25 cm. (3–3.25 in.); and to Schroeder, 6.5—9.5 cm. (2.5–3.75 in.). As pelves with a conjugata vera above 8½ cm. (3⅜ in.) offer a reasonable chance to both child and mother at term, and those below 7 cm. (2¾ in.) offer no chance to the child, I think that the operation should be restricted to these limits; that is between 7-8½ cm. (2¾-3⅜ in.) in simple flattened pelves. In the justo-minor pelvis a conjugata of 9½ cm. (3¾ in.) or less will usually be an indication for the operation. In the rare forms of obliquely narrowed pelvis, whatever the cause, we must be guided almost entirely by the history of previous labors.

We thus have the operations restricted to a very small range, 1½ cm. (⅝ in.), which should only be exceeded when the previous history tells us that the previous labors have all ended disastrously. We should not think of inducing labor in a flattened pelvis with a conjugata below 7 cm's. (2¾ in.) for in that case the prospects for the child are almost *nil* and the dangers to the mother greatly increased. Here we come to the relative indication for Cæsarian section, when it is best to allow the woman to go on to term, and attempt to save both mother and child by that operation.

With these contracted indications, we readily see that an accurate idea as to the exact size and form of the pelvis is an absolute prerequisite for the performance of the operation; and the only means by which we can accurately obtain this information is by carefully measuring the pelvis. We should not content ourselves with simply measuring the conjugata vera, but should also take the external measurements and thereby attempt to determine with what form of pelvis we have to deal. After doing that, we must carefully examine the interior of the pelvis to determine its height; to see if it is generally contracted, and if contracted, if the contraction increases as we approach the outlet, we must look for exotoses of the pelvic bones and carefully examine the promontory to see if it is double or not. If we think the pelvis contracted laterally we should measure the distance between the tubera ischiorum on each side, as Breisky recommended. We should also attempt to estimate the transverse diameter of the pelvis, which is most difficult to do, and the most that can be expected is to examine alternately with each hand and try to stroke the linea innominata and so relatively to get some idea as to the transverse diameter.

Having decided that an operation is necessary, the next question is, when shall it be done? Of course, the younger the fœtus, the smaller will be its size, and consequently the easier its delivery. But, unfortunately, the smaller the fœtus, the less chance will it have of living even if it survive the operation. Generally speaking, we say a child is viable after the twenty-eighth week, but its chances of living are almost *nil;* indeed children 30-32 weeks old have next to no chances of living. The later the operation, the more chances has the fœtus of living after it, but unfortunately its size and consequently the difficulty of its delivery increase with its age. If possible, the operation should be done about the 34th–36th week, our object being to operate at the latest possible period consistent with safe delivery. To fulfill this object we must attempt to gain an accurate knowledge as to the size of the child's head. Unfortunately, we are unable to determine its size with mathematical precision or even with the relative precision of pelvimetry; so we are obliged to take advantage of every possible hint on the subject. Some of the following points may be of assistance in different cases. We must consider the mother's account as to the duration of the pregnancy.

Notice the size of the parents, large parents usually having large children. Inquire about the previous labors, particularly as to the size of the head. Endeavor to estimate the size of the head by abdominal and combined abdominal and vaginal palpation; and note the consistency and amount of resistance to compression that the bones of the head offer. Try to measure the head with the pelvimeter through the abdominal walls, and deduct the estimated thickness of the abdominal walls from the result. Notice the size of the large anterior fontanelle, average width 2 cm.; the width of the sutures; and the distance from the anterior to the posterior fontanelle; for as they are larger or smaller, it indicates a larger or smaller head. Measure the length of the fœtus as it lies in utero, from breech to vertex, double the measurement and it gives, according to Ahlfeld, the length of the fœtus. If a foot is prolapsed, measure it, for Gœnner stated that there is a difference of nearly one centi-

meter between the length of the foot at term and one at thirty-two–thirty-four weeks.

One of the most important methods is that of Mueller who attempts to force the head down into the pelvis by pressure from above. As long as he is able to force the head down, he knows that labor will readily take place, but when he can no longer force the head down and when it bulges out over the symphysis, then he considers that the time for operation has arrived. As the great danger to the mother is from sepsis, one cannot be too careful in one's efforts to guard against it, and consequently one should be most particular in one's preparation for the operation. For several days previous to operating, the woman should have a warm bath daily; and several times a day be douched with warm water, 95–98 F., containing salt or borax, by which the cervix is softened and dilated. Just before operating, the genitals should be most carefully washed with hot water and soap, followed by a 1–1,000 bichloride solution; the vagina should also be most carefully cleansed.

The hands of the operator should be washed for at least ten minutes in hot water and the nail-brush vigorously used, after which they should be placed for several minutes in a 1—5,000 bichloride solution. All instruments should be sterilized by steam or placed in a 5 per cent. solution of carbolic acid for at least thirty minutes.

The most generally approved method is that of Krause or the introduction of a disinfected flexible bougie between the membranes and the uterine wall. If properly conducted it is almost entirely devoid of danger for the mother, and will bring about the birth of the child in a period varying from 8-241 hours, averaging about eighty hours or about three days. To insert the bougie, the woman is placed on her back or side as may be convenient, and the cervix brought down by a pair of bullet forceps and the cervical canal carefully cleansed with bichloride on a pledget of cotton; the bougie is then carefully inserted so that its lower end is within the vagina, care being taken not to wound the membranes or the placenta. Then the vagina is packed with iodoform gauze, which serves to hold the bougie in place. If at the end of twenty-four hours no labor pains have been produced, the bougie should be removed and another introduced at another point under the same precautions as the first. If this method fail we may resort to Kiwisch's method of allowing a current of hot water, 100–110 F., to flow through the vagina several times a day for a period of 5–15 minutes. Or we may puncture the membranes, as accessory to these, we may loosen the membranes about their lower pole; tampon the vagina with iodoform gauze or employ Barnes' bags. If the pains are weak, Fehling recommends a version by Hick's method and bring down one leg, whereby increased contraction is produced and one is afforded a ready means of ending the labor if one deems it expedient in the interests of the mother or child.

Dr. Neale: I regard the chief point in this very able paper to be the endeavor to definitely fix the limits for the induction of premature labor in contracted pelves, not as opposed to Cæsarian section, but as applicable to a distinct and separate class of cases. This endeavor I strongly advocate, but at the same time must confess that I do not believe the plan is always practicable at the bed-side. There are so many factors entering into the determination of this question as stated in my paper, that I can now only repeat what I there quoted, viz.: "A given pelvic measurement is useful as an indication of what has been the experience of others under similar circumstances, but is not a final ground for decision." After the evidence adduced, which doubtless represents the opinion of the best medical authorities, I am sure I only voice the concurrence of this society in accepting the limits for this operation as stated by Dr. Williams. This is practically in accordance with the teachings of Lusk—probably our strongest American authority—who places the range for the induction of premature labor in contracted pelves at a conjugata vera of from $2\frac{3}{4}$ inches (7 cm.) to $3\frac{1}{2}$ inches (8.75 cm.).

Dr. Kelly: The subject is too large to be discussed formally. What we want to know for practical purposes is, whether the children live any time after they get home. My own experience is but few live. If they are sent out simply to die soon after at home, the induction of premature labor among the poorer classes simply becomes a species of uterine gymnastics.

A method of my own which I have found most successful in inducing premature labor, is taking a flexible whalebone bougie, introducing it between the membranes and the uterine wall, high up into the uterus, and sweeping it gently around for one or two inches in either direction. This has not failed me in any instance in bringing on labor.—*Journal of Gynecology.*

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few para graphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE MEDICAL AND SURGICAL REPORTER.

With the present number the editorial management passes into other hands.

For nearly 40 years the REPORTER has held an exalted position among medical periodicals. The liberal policy which has always characterized its management, the high class of material which has filled its pages, its unqualified and unselfish devotion to the highest interests of the profession, its large and disseminated list of readers both in this country and abroad, and its long list of subscribers who have continued to read it almost since its very inception, give it a place almost unique.

In the future, as in the past, the same broad, liberal, and progressive policy will be pursued; quality alone will determine the admission of articles to its pages; it owes no allegiance to any school or faction; it is pledged for higher medical education and for legal enactment to prevent the incompetent from practicing medicine.

Notwithstanding the commanding position attained by the REPORTER we are not satisfied to let well enough alone and thus sow the seed of early decay. Therefore, with the promised co-operation of a large number of the most prominent writers in this country and Europe, with the assurance of the continued liberal support of our old contributors and subscribers; and having accomplished important changes in the present number, and with others in view in various directions in the literary and typographical make-up of the REPORTER, we are confident the journal will be more welcome than ever, and its patronage and influence greatly increased.

In these busy days when every moment is preyed upon and when thousands of presses are offering us the results of an ever-increasing amount of observation, it becomes a necessity that for the practitioner to keep abreast of the times the essential part of this mass of work should be so condensed and arranged that "he who runs may read." With an increase of the size of the REPORTER from **28** to **40** pages of reading matter, and with the aid of a competent corps of assistants we hope to keep our readers posted in all important progress in medical science and art. To this end our editorial columns will be devoted to Leading Articles which will consist largely of short critical résumés of the more important and recent advances. The Periscope will also be modified—it will follow the editorial columns, and the abstracts will be arranged collectively for ready reference according to the special departments in medicine to which they belong.

The REPORTER has always been preeminently a journal for the practicing physician, and we will spare no effort to keep it so; but while the practical will always be foremost in view we will endeavor to neglect nothing which promises to be of value to the clinician or which is of special interest to the profession.

Space does not permit us to offer in detail what we have done or intend to do, but it is hoped that these few statements will be sufficient to indicate our position, and our determination to secure the best material to be had and keep our readers thoroughly informed in a concise and practical way of medical progress.

We ask the indulgence of our readers for any shortcomings in the present number. Owing to a misunderstanding with our predecessor, our task was one of exceptional difficulty.

As we are going to press, it is announced that Dr. Joseph Leidy, the eminent naturalist and Professor of Anatomy in the University of Pennsylvania, is lying critically ill, and it is not likely that he will live twenty-four hours.

THE DANGERS OF COCAINE.

The rapid accumulation of cases in which alarming symptoms followed the local application of small quantities of cocaine, together with the fact that these untoward effects are due to individual idiosyncrasy and do not invariably occur immediately, is a positive warning to the profession that this powerful substance should not be used in any case for the first time without proper antidotes directly at hand and the patient kept under surveillance for at least a half hour. We will not attempt to refer to the cases published in which ordinary therapeutic doses administered internally or subcutaneously caused symptoms similarly embarrassing.

Nearly three years ago, Satterwhite, as a result of a study of one hundred cases of poisoning by this alkaloid, called attention to the dangers attending the use of even very small doses, and at about the same time another author after summarizing the records of fifty cases made a similar announcement. That this warning was well founded is evident by succeeding publications. A case is reported by Broughton in which unconsciousness; an irregular, slow respiration; and a slow pulse, followed the application of three minims of a twenty per cent. solution within the cavity of a tooth. Whistler, after the application of a four per cent. solution to the nasal cavity, noted vertigo and threatening syncope. In a case of glossitis, Ricket states, that the patient became moribund after the use of a similar solution. Myrtyle dropped three minims of a three per cent. solution in each eye, which immediately caused a sense of numbness in the back of the tongue and throat, palpitation, threatened syncope and nausea. Bettleheim records that in one case the hypodermatic injection of one-sixth of a grain induced alarming symptoms; and in another, one-eighth of a grain similarly injected caused unconsciousness, congestion of the face, irregular breathing and trismus. Cotter found unpleasant symptoms in more than one instance while using in the nasal cavities a solution as weak as ten per cent. Thus, in a young lady there was sprayed into these fossæ six or seven minims of a ten per cent. solution, and just as he was going to operate, the breathing became very difficult, the larynx seemed paralysed, distressing symptoms of cardiac and general depression appeared, and she was unable to walk for two hours. Hübner dropped about one and a half minims of a two per cent. solution into the nostril of a healthy young soldier previous to the removal of a polypus. This was soon followed by unconsciousness, an exceedingly weak pulse and cold skin. A case is reported by Ficano of a woman, forty-three years of age, who had for some time suffered from intolerable tinnitis, which accompanied a dry otitis media, with a diminution of hearing. A few drops of a five per cent. solution were introduced into the middle ear by means of a catheter, after the use of the Politzer method of insufflation. In a short time vomiting came on with cramps and diarrhœa which lasted for several hours, there was marked muscular inco-ordination, and symptoms generally analogous to those of sea-sickness.

There seems to be no doubt that cocaine is absorbed with extraordinary rapidity, and that the stronger the solution which is

locally applied the greater the danger of toxic symptoms, but whether the latter are to be attributed merely to the larger dose or to some obscure action is not apparent. Falk has found that the rapidity of absorption varies in the different tissues—absorption taking place most rapidly through the conjunctiva, then in the following order: nose, larynx, mouth and ear. It is generally conceded that a ten per cent. solution is sufficiently strong for most purposes and robbed of many of the dangers of those of greater strength.

The nature of the toxæmic symptoms varies so greatly that no rule-o'-thumb treatment can be set down: in some cases nervous and muscular excitement predominates; in others, respiration in the function most seriously affected; in others, the circulation, etc. Among the agents found useful are nitrite of amyl, strychnine, atropine, morphine, alcohol, ammonia, digitalis, chloral, seria-prisms over the heart and stomach, hot drinks and artificial respiration.

CORRESPONDENCE.

"Little Liver Pills."

℞

Calomel	gr. ½
Podophyllin	"
Extract of Belladonna	"
Aloin	a a gr ⅛.
Oleoresin of capsicum	
Ipecacuanha	a a gr. 1-16

M. Ft. Pill. No. I. Dose: as an aperient, one pill at night or morning; as a laxative, one or two; as a cathartic and cholagogue, three or four—(one every two hours until the desired number has been taken).

This is a reliable anti-bilious remedy, equal, if not superior, to the compound cathartic pill of the U. S. P. It is an improvement on the popular little "Lapactic Pill," the mercury and podophyllin greatly enhancing the hepatic tendency of the aloin and belladonna pill, while the omission of the strychnia renders it more suitable for children. Practically, this little pill leaves nothing to be desired.

Each pill weighs one grain.

B. Frank Humphreys, M. D.

PERISCOPE.

THERAPEUTICS.

THE EMPLOYMENT OF NAPHTHALINE IN THE TREATMENT OF TYPHOID FEVER.

Natanson (*Rev. Gen. de Clin. et de Therap.*, March 11, 1891) has communicated to the *Société de Médecine Pratigue* the results of his experience in the treatment of typhoid fever by naphthaline. He has employed the drug in 23 cases, and at different periods of the malady. The temperature and the diarrhœa were diminished within two or three days. The remedy was given daily three or four times, in doses of 15 centigrammes for adults, and 10 centigrammes for children. In order to continue the use of the medicament the stools and the urine should be carefully examined. The disappearance from the stools of the microbes, shows the success of the treatment; but a greenish coloration of the urine is a sufficient cause for the suspension of the drug. The remedy may be given in gelatine capsules or in water. To this treatment may be added as auxiliary, other tonic measures, such, especially, as cold-water baths. The healthy condition of the kidneys must be watched in order to avoid toxic phenomena.

HYPOSULPHITE OF SODIUM AND SILVER IN ATAXIA.

Dr. A. Radcliffe in the *Therapeutic Gazette* writes: Having a case of locomotor ataxia to treat, and fearing the danger of argyria from the nitrate of silver, I was induced to use the hyposulphate of sodium and silver, thiosulphite of sodium and silver, from a report published by Curci, in the *Medical News*, July 10, 1886, wherein it was claimed this double salt "did not coagulate the albuminoids, is very soluble in water, is not caustic, is diffusible, promptly absorbed by mucous membrane and connective tissue. Its taste is sweet, slightly nauseous. Should be given fasting or hypodermically, by mouth from 5 to 20 centigrammes daily, or hypodermically from 1 to 5 centigrammes daily. Its action is quickly obtained; the danger of argyria is avoided."

My patient was a lady, past middle life, and her trouble had been slow in coming on. The electric-like pains had been treated as neuralgia and rheumatism; the gastric trouble, as dyspepsia, with pepsin and nux vomica; while the difficulty in locomo-

tion was attributed to the rheumatism. She came under my care early in 1886. The first symptom she then complained of was the difficulty she had just experienced in coming up the stairs, owing to the darkness, and some stiffness in her limbs. Though she could walk from her house to the gate at night with considerable certainty, as she was familiar with the locality, yet if she stepped off the walk she would be compelled to sit down, because on the ground she could not get her bearings; that if she did not get back on to the walk, she would be compelled to crawl to the house, for on the ground she felt an uncertainty about her equilibrium. She does not walk on her heels, bringing the sole down with a flap; she walks slightly bent forward, that she may watch where she steps, for a very small obstacle, if stepped upon, is sufficient to cause her to fall. Though she stands with her eyes closed, yet there is a slight swaying motion of the body, such a feeling that she might fall, she does not like to try it. She stands and walks wide; the foot is not carried directly forward with a good knee action, but is held rather stiff and swung around.

She took at first ergot, to relieve some spinal congestion that troubled her in the mornings. Belladonna, she thought, gave little relief to the bladder-trouble (paralysis of sphincter), and annoyed her by the dryness it caused in the mouth.

She has taken the sodium and silver salt at intervals since 1887, or earlier, as high as 15 centigrammes (2¼ grains) a day, in all four or five drachms, and has lately commenced on another drachm. Soon after commencing the use of the silver salt her gait improved, and she walked with more ease and spring. She says the silver helped the pains in her limbs, that she could walk better after taking it, but it did not help her bladder-trouble.

Suspension, which she uses at home, she claims greatly helps the bladder-trouble; the only thing that ever did.

With the silver salt and suspension, she says, she can get along very well, if her household work is not too great; that without them she could hardly get along at all.

TREATMENT OF ERYSIPELAS BY ICHTHYOL.

An elaborate research, clinical and bacteriological, has recently been published by Professor Nussbaum's assistant, Dr. Julius Fessler, on the treatment of erysipelas by ichthyol, a plan which has been for some years extensively adopted in Munich. From laboratory experiments it was evident that, though ichthyol has only a slight effect in preventing the development of staphylococci, it has a very potent deterrent influence on the multiplication of streptococci, and it is well known that it is the latter kind of bacteria that are the cause of erysipelas. The method of treatment consists mainly of rubbing a strong ichthyol ointment energetically, and for ten minutes at a time, into the affected surface and its neighborhood; ichthyol in the form of pills may also be given internally. Where there is a wound it must be very carefully disinfected, and an antiseptic dressing applied. The results of this treatment, as compared with ordinary methods, are embodied in several instructive tables. From these it appears that, while the mean duration of the cases treated by other methods from 1880 to 1888 was about twelve days, in no single year falling below nine days, the cases treated by ichthyol from 1886 to 1888 presented a mean duration of under seven days, while in the first half of 1889 it fell to 5.6 days.—*Lancet.*

ON THE ACTION OF ATROPINE IN DISEASES OF THE HEART.

Dr. Cardarelli has experimented with atropine in sixty-five cases of various forms of functional cardiac disease, measuring the pulse with the chromograph of Verdin and the arterial pressure with the sphygmomanometer of Basch. His conclusions, which appear to be based on a most careful study, are published in *La France Médicale*, January 23, 1891:

1. Atropine, in doses of $\frac{1}{120}$ to $\frac{1}{32}$ grain, given hypodermically in man, manifests itself first in its action on the heart.

2. The action of atropine on the heart consists in the overcoming to a greater or less degree of the inhibitory influence of the vagus nerve.

3. As a consequence of this paralyzing action on the vagus, there is constant acceleration of the cardiac rhythm, which may be in certain cases accompanied by a slight transitory slowing.

4. Arterial pressure is reduced under the influence of atropine in direct proportion to the acceleration of the rhythm.

The author concludes with the statement that, when a clinician cannot use atropine in slight forms of irritation of the pneumogastric, in which there is no slowing of the pulse, it will be, nevertheless, a great error not to prescribe atropine in cases where a

permanently slow pulse is accompanied by epileptiform vertigo, and, above all, by syncope.—*Therapeutic Gazette.*

ARISTOL IN DISEASES OF THE EYE.

Aristol has been employed successfully by A. Bourgeois (*Union Méd* du *Nord-Est*, Feby., 1891), in eye diseases, such as ulcers of the cornea, traumatic keratitis, and wounds caused by foreign bodies, or the extirpation of an epithelioma. In a case of corneal ulceration he recommends the following treatment:

1.—Instillations of cocaine between the eye-lids.

2.—Frequent washings of the conjunctival cul-de-sac with a 20 to 1000 solution of the biniodide of mercury.

3.—Instillation upon the cornea of a drop of eserine, to be followed by the local application of the powder of aristol.

4.—Corrosive sublimate, dressing and bandaging.

The indications for the use of aristol in ophthalmology, according to the author, are those connected with the drying up of suppuration, or the cicatrization of wounds. The drug has advantages over iodoform as well as in infantile medicine.

DIGITALIS AND STRYCHNINE AS CIRCULATORY STIMULANTS.

Digitalis, caffeine, strophanthus, scoparius, and adonis vernalis constitute a most useful group of agents that exhibit an action upon the circulatory apparatus commonly spoken of as tonic or stimulant; but, when the physiological effects of these drugs are considered critically from the stand-point of their application to diseased states, it will be seen that their use is more limited than is generally supposed. The concomitant actions upon parts and functions of the organism, other than the heart and circulation possessed by each, frequently present a barrier to their employment, even where the circulatory symptoms would seem to indicate their prompt administration. The indications for the use of digitalis in heart affections are clearly understood, but the reasons for and against its use in many cases of a weakened and failing circulation do not appear to be as firmly established. This view of the question, together with strong arguments for the use of strychnine as a circulatory stimulant, form a basis of a valuable paper published by Dr. Bradfute (*New York Med. Journ.*, January 10, 1891), who, in the first place, maintains that in the class of constitutional diseases, especially those characterized by a continuous high temperature, accompanied by any of the various forms of degenerative change in the organs and muscular system, digitalis is not the remedy, and where these changes affect markedly the cardiac structure it is conspicuously contra-indicated. The action of the drug upon the muscular fibre is one of stimulation, followed by an increase in its force power, and if the fibre is surrounded by, or contains within, its substance granules or particles of fatty change, it can be readily seen that the indications are for the relief of overwork, and not to compel it to do what it is already physically incapacitated to perform. For example, in typhoid fever the condition just outlined is always present, and the administration of digitalis in doses sufficient to produce even a slight physiological effect cannot fail to do harm; but that this fact is frequently overlooked, and by practitioners of eminence, there is ample evidence. In addition to the ugly action of digitalis upon diseased heart-tissue, its property of contracting the arterioles, causing a rise in the blood-pressure, increases the total amount of cardiac work necessary to be done, which is so injurious as to result sometimes in practically a paralysis of the entire organ,—a mishap that has occurred after a sudden change from the recumbent to the erect posture in instances of undue exhibition of the drug where there was no interference by disease with the normal function of the heart-fibre. Its influence upon the inhibitory centres also offers an obstacle to its use when the above-mentioned objections may not exist, and on account of this it is well to remember that, as a rule, subject to modifications attendant upon exceptional cases, a weak and slow heart is not amenable to the curative effects of digitalis; rather is it a weak and rapid heart that presents the most favorable opportunity for the display of its peculiar action. Phosphorus-poisoning, typhus and yellow fevers, atheroma, and fatty heart are affections presenting a pathological anatomy contra-indicating the employment of digitalis, especially in the last stages of these diseases. Aside from its use in simple heart-disease, unless very skillfully handled, digitalis is only effective in the failing circulation of hemorrhage, shock, and certain acute affections, especially when the cardiac movements are very rapid, where the result desired is a bracing up, as it were, of the general circulatory apparatus until nature has time to recover herself. In

shock following head injuries, when the heart is slow, nitro-glycerine is the better agent, as it paralyzes the inhibitory centres and dilates the arterioles, thus promoting the activity of the heart and increasing the rapidity of the blood current. But in these instances there are no degenerative changes in the heart muscle to negative violent stimulation of the fibre. In acute phthisis, accompanied by an irritative fever and a rapid and sometimes tumultuous heart, digitalis is often very useful, but it is manifestly unsafe to administer it in large doses. The Harveian lecturer of 1890 calls attention to the independence of the systemic and pulmonary circulations, which opens up a new field for the study of pulmonary therapeutics; and it may be that future experiments and observations may preclude the employment of many of the drugs now used in lung-affections; but, under our present knowledge, digitalis is an excellent remedy for the failing heart of continued pulmonary hemorrhage and the gray hepatization stage of pneumonia. In the latter, digitalis does good so long as the heart does not beat below the normal rate; when the pulse drops below 70, some other remedy must be given. In the first and second stages of pneumonia, when active inflammation is going on, digitalis is out of place, as it only causes the heart to pump more blood into an already surcharged area, and can have but little influence over the temperature. In myocarditis, where exudative material is poured out in and around the muscular substance, digitalis adds insult to injury, and the interference with function from the disease is only increased.

From these few remarks it can easily be seen that some of the contra-indications that may be present in disease prohibiting the use of the digitalis, or a remedy having a similar action, are congestion and inflammatory obstruction in the pulmonary structure; degenerative changes in the muscular system, including the heart; general interruption of the nutritive processes, with accumulation of serum in the tissue; sudden cardiac failure; and all conditions in which the heart-beats are less than normal. Of course, no iron-clad rules can be laid down; but if the drug is given in maladies characterized by any of the above-mentioned lesions, it must be used with great care.

In selecting a remedy to combat a failing circulation, all the structural changes and diminished or lost functions must be accurately studied and the influences resulting therefrom duly considered. Without the intelligence accruing from such a consideration of a given case, it is impossible to apply a proper drug, no matter how well known is its action. A thorough knowledge of the normal physiological state of the patient, the pathological changes that have taken place, and the physiological action of the drug is essential to successful therapeutics, and in no instance is a familiarity wiith these three points more important than in a case of failing circulation.

In those protracted diseases in which this formidable symptom arises, the general condition of the patient may be summarized as follows: The muscular system is weak, flabby, degenerated, and ill nourished; the nervous system is reflexly disorganized; the nerve-conducting paths, chiefly at the periphery, are partially or entirely obstructed, so that tissue sensation and motility are interfered with and vaso-motor paresis is marked, thus checking normal physiological change in part or even in places completely; the secretory structures are either exhausted—not functionating—or their products are unfit for use; the circulatory apparatus is devoid of tone and strength; and the total area of blood space is increased, owing to paretic dilatation of the smaller vessels. In such a condition here presented the failing circulation is due not so much to the disease *per se* as to vitiated anatomical structure and physiological function, and the indications for treatment are plain. The prime object to be desired is the restoration of the function of the spinal cord, reflex centres, and nerve-endings. A drug that will do this causes a cessation in the destruction of tissue and less waste, thereby minimizing the the drain upon the nutritive elements of an already deteriorated blood; vaso-motor tonus returns, the arterioles and capillaries contract, the superabundant vascular space disappears, and hence a larger amount of blood passes through the heart at each cardiac cycle, stimulating its action and promoting its nutrition.

Strychnine seems to fulfill all the indications in the morbid condition above described, for the action of this remedy being expended upon the spinal cord and this part of the nervous system in conjunction with the sympathetic playing so important a *rôle* in repairing and maintaining the various processes of organic life, it is natural to infer that an intelligent stimulation of its functional activity would, under such circumstances, be a perfectly logical procedure, provided no structural lesion existed in its substance. Clinical experience seems to

have established the truth of this reasoning, and Dr. Bradfute extends this evidence with the report of several cases in which symptoms of profound collapse were overcome by the use of strychnine. Its administration must, however, be guided by the effect produced. $\frac{1}{60}$ grain of the sulphate may be given hypodermically every two hours, or oftener if nesessary, until there is the desired response. It is interesting to note that in such a condition of the system large amounts are easily borne, especially if the patient has been taking large amounts of alcohol, and the author states he has given as much as four grains in twenty-four hours without producing toxic symptoms. The failing circulation of diphtheria is a typical one for the exhibition of strychnine, for in this affection in its severer forms we have all the conditions present to which its action is antagonistic.—*Therapeutic Gazette.*

THE TREATMENT OF CHRONIC RHEUMATISM.

The following prescription is recommended in the treatment of chronic rheumatism, by Fothergill (*Prog. méd., Jan.* 10, 1891).

℞

Arsenious acid	1.20 grammes.
Powdered guiac	12 "
Pulverized capsicum	2 "
Aloes and myrrh	12 "

Make 120 pills. A pill to be given 3 times a day, together with a diet rich in fatty substances.

MEDICINE.

BRIGHT'S DISEASE FOLLOWING INFANTILE PURPURA.

A Moussous (*Rev. mens. des malad. de l'enfance*, Feby., 1891, p. 62) reports two cases of purpura in children, followed by Bright's disease. In one of them, that of a child ten years of age, suffering from a rheumatoid purpura, with hæmatemesis, albuminuria with œdema of the extremities and face, and disturbances of sight, came on two months afterwards. The second case was fatal. It occurred in a child, aged thirteen years, who had likewise gone through an attack of purpura. Hæmaturia, albuminuria and anasarca followed, accompanied with petechial eruptions, the patient dying four months afterwards with uræmic and dyspnœic symptoms. Post-mortem examination showed enlargement of the kidneys, and under the microscope lesions due to a diffused nephritis were observed.

A CASE OF PERNICIOUS ANÆMIA OF PARASITIC ORIGIN.

Dr. M. Kotcher (*Bolnitcheraja Gazette, Botkina*, November 1st, 1890) quotes a number of authors who are against and for the fact of intestinal parasites, especially Tænia Solium and Botriocephales Latus, often inducing pernicious anæmia with all its symptoms and signs. The majority of the quoted authors submit to the fact that very frequently desperate cases of pernicious anæmia have been known to occur in practice which depended immediately upon the mentioned parasites. In the author's own case, which was a typical one, of pernicious anæmia, improvement followed after the expulsion of the parasite. He believes that the presence of the tænia and Botriocephalus does, in many cases, cause the whole train of signs and symptoms mentioned, as characteristic of idiopathic pernicious anæmia, and quotes amongst others, Dr. Roosevelt (*N. Y. Medical Record*, 1888), who believes in the same.

CARDICE NERVE STORMS, OR ESSENTIAL TACHYCARDIA.

Dr. H. C. Wood, in a study of several important cases of this nature, in the *University Medical Magazine*, gives some interesting points.

The definition of the disease, he writes, would be a recurrent paroxysmal neurosis, in which attacks of excessively rapid heart action occur without obvious immediate or predisposing cause, and without pronounced pain or excessive cardiac distress, the pulse rising to 160 and upward, the sounds of the heart remaining normal; and it being frequently possible to arrest the attacks by drinking a glass of cold water and certain other procedures of apparently trifling import; the disease having apparently no tendency to shorten life or to develop organic disease, and being entirely compatible with great mental and physical activity.

The length of the attacks was from a few minutes to several hours. Sometimes they would be shortened by the patient taking a long breath, and whilst still holding his breath, drinking a glass of cold water. When about half a glass was taken the heart would suddenly quiet down, three long slow beats would follow one another and the normal beat be attained. Sometimes, however, the attack, instead of being shortened by this procedure, would be only momentarily interrupted. There was no evidence

of valvular or other heart disease during or between the paroxysms.

One of the most curious phenomena of tachycardia is the arrest of the paroxysms by the swallowing of cold water, which is probably a characteristic feature of the disease, since it has been noted in almost all the elaborately observed and reported cases. It affords a plausible argument against the probability of the rapid pulse being due to pneumogastric paralysis, since Dr. S. Meltzer has shown that swallowing is attended with a loss of tone in the vagi centre, and consequent weakening of cardiac inhibition and increased frequency of the cardiac beats. It is, however, probable that the arrest of the tachycardiac paroxysms by the swallowing of hot or cold liquids, is due to stimulation of the inhibitory cardiac centre, produced by irritation of the peripheral nerve filaments of the stomach. It is a well-known physiological fact that irritation of the abdominal nerves is capable of reflexly inhibiting the heart, and in one case it was found that the best method was to swallow the water as rapidly as possible and as cold or as hot as could be taken; if the water is only moderately cold, much larger quantities of it are required.

AN EARLY ATAXIC SIGN.

Weiss, of Vienna, says that an early symptom of locomotor ataxia is an inability on the part of the patient to walk backwards, while as yet, and in other ways, he may be able to walk with firmness and rapidity. Perron, of Bordeaux, has also, as we stated several weeks ago, recently suggested an early diagnostic sign, which is simply a modification of the Romberg test,—namely, causing the suspected ataxic patient to stand upon one leg, instead of two, with the eyes closed. If the patient shows a tendency to fall, it may be inferred that the spinal trouble has begun which will lead on to locomotor ataxia, even if the Romberg test fails, as it not infrequently does in cases that are not well advanced.—*New York Medical Journal.*

CHLOROSIS AND ITS TREATMENT.

Dr. Frederick Scholz, of Bremen, has published a remarkable work on chlorosis, the outcome of observations made during the last twenty years. Instead of regarding the deficiency of iron or hæmoglobin, or even that of the red corpuscles, as the primary affection, he states that contraction of the vessels is always present in these cases, as indeed was observed by Bamberger, Rokitansky, and Virchow; and this, he contends, is not to be regarded as a complication due to an altered condition of the blood, but as the primary condition which is followed by the morbid change in the blood. As a matter of fact, the vessels are, he says, too full, or in the condition termed by the older physicians "plethora ad vasa," the blood being—or becoming—abnormally serous. Long ago his attention was struck by the cold and livid condition of the skin in anæmic subjects, and he was led by this to employ hot baths, together with gentle friction, in the treatment, with the view of acting directly upon the skin, so as to improve the vitality and nutrition generally. The success of his first attempts was so marked that he was encouraged to persevere in this line of treatment, and he has since had many opportunities of extending his experience with it. Hot baths diminish the plethora by relaxing the tension of the vascular system, which is high, quickening the circulation, and thus relieving the palpitation, dyspnœa, and other symptoms. In thirty cases where the distress of the patient was very great, Dr. Scholz has gone a step further and supplemented the hot bath by venesection. Paradoxical as this treatment may appear, it was followed by marked benefit, and if the theory of the pathology of chlorosis above mentioned be correct, there can be little doubt that the novel line of treatment practised by Dr. Scholz is justifiable.—*Lancet.*

SURGERY.

SURGERY OF THE LIVER.

An excellent paper on the surgery of the liver, based upon nine very careful observations, is published by Terrillon (*Bull. Gener. de Therapeutique*, Feb. 15, 1891). The subject is studied under the topics of *Puncture and Incisions; Operations upon the Gall-bladder; Opening of Hepatic Abscesses;* and *Resection of the Liver.* The author arrives at the following interesting conclusions:

1. The surgery of the liver only demands special precautions which can easily be applied. Under ordinary antiseptic measures, punctures of the liver are inoffensive.

2. The gall-bladder can always be opened and drained. This operation is known by the name of *cholecystectomy.* If there is obstruction of the ductus choledochus, opening of the gall-bladder is a simple palliative. When it is permeable, the cure is rapid, and

no fistula will remain. Nevertheless cholecystectomy should not be practiced unless under special indications. Its utility is not unfrequently doubtful, whereas simple incisions with proper drainage give equally good results.

3. The ablation of a piece of liver is an easy and benign procedure. To insure hæmatoris a band of caoutchouc may be placed between the healthy portion and the diseased part.

THE PROPER TIME OF DAY IN WHICH TO OPERATE.

Surgeons have been divided in their opinion as to which part of the day is the most favorable for the performance and successful outcome of operations. The *British Medical Journal* discusses the matter in a recent number, stating that the advocates of morning operations assert that the patient is thereby saved the suspense of waiting until the afternoon, and that a better supply of sun-light, or its equivalent, can be depended on. Others, instead, say that morning operations imply an anxious and sleepless night for the patient, and that as night comes on more rapidly when the operation is performed in the afternoon, better chances for the patient's rest and sleep are secured. They also state that long operations seriously tax a surgeon's nerves and strength, and that for that reason the afternoon is preferable. In this respect we cannot altogether agree with them, thinking that by morning operations the surgeon secures the time at which he is best provided with muscular and nervous force, that have not been exhausted by the forenoon's work. We are also inclined to think that whether the operation be done early or late, its influence upon the previous night is about equal in either case. Those who operate frequently in the afternoon know the discomfort of finishing their operations by artificial light.

The *Journal* states that wherever freedom from noise and plenty of warmth can be procured, especially in summer, morning is probably the best time. We are inclined to think that, as darkness comes early in winter, morning operations are also indicated at that season.—*International Journal of Surgery*, Feb., 1891.

A NEW METHOD FOR THE TREATMENT OF INJURIES TO THE SHOULDER.

Dr. Monks reports about twenty-five cases, including some in which rheumatism undoubtedly played a prominent part. In most of the cases the ordinary methods of treatment had been tried in vain. The result was a more or less perfect cure in about two-thirds of all cases tried, in a period of time varying from a few days to a few weeks. The most hopeful cases were those which were purely traumatic. The principal involved in the treatment was that the shoulder is more perfectly in a condition of actual rest when the arm is *supported at right angles to the trunk*, than when the elbow is kept at the side, because (1) the weight of the upper extremity is thus entirely taken off the shoulder; (2) the deltoid and other structures covering the joints are relaxed; (3) the circumflex nerve and other deeply seated structures are relieved from pressure. In applying this method of treatment, the whole weight of the upper extremity is taken upon the platform-shaped splint, which is supported by a firm band of webbing passing over the other shoulder. The cases for which this form of treatment is especially adapted are, those where the prominent symptoms are persistent pain and tenderness in the shoulder, or inability to raise the elbow from the side.—*Boston Med. Journal.*

THE PREPARATION OF LIGATURES.

Dr. J. Schou (*Ugeskrift for Læger*) recommends the following methods of preparation:

1. Sublimate Catgut: Commercial catgut is wound upon glass spools and placed in 5 per cent alcoholic solution of corosive sublimate. This solution is changed repeatedly until it remains clear (Bergmann). Another method is to place the catgut in a 1 per cent. solution of sublimate for twelve hours, and then to preserve it in a one-half per cent. sublimate solution containing 10 per cent. of glycerine (Schede and Kümmell).

2. Carbolized Catgut: Commercial catgut is wound upon spools, and placed for forty-eight hours, in a 5 per cent. solution of carbolic acid. It is then transferred to a vessel containing a fresh solution of the same strength, when the gut is removed from the spool, and then again firmly wound upon it and preserved in a 5 per cent. solution of carbolic acid in alcohol (Block).

3. Carbolized Silk: The silk is boiled in a 5 per cent. carbolic solution for a period varying from ten minutes to an hour and a half, according to the strength of the silk, the fluid being renewed every half hour. The silk is preserved in 2 per cent. watery solution of carbolic acid (Czerny).

4. Sublimate Silk: The silk is boiled for two hours in a 1 per cent. sublimate solution, and preserved in a 1 to 1,000 solution

(Schede and Kümmell).—*Deutsche Medizin, Zeitung*, Jan. 22, 1891.

Transplantation of Tissue from Lower Animals to Man.

The case of transplantation from an animal, recently performed at Charity Hospital, New York, by Dr. A. M. Phelps, has commanded a wide-spread attention, and all sorts of absurd rumors have been circulated. The operation is a success in so far as it establishes the principle that it is possible to grow large masses of tissue from an animal to man, and to establish the circulation until the union takes place between opposite species without danger to either. It also demonstrates that a growth of new bone takes place when a section of bone is transplanted and its nutrition maintained by the artery of the animal. This, if continued four or five weeks, would probably unite a fracture. Owing to the inefficient dressings which are apt to occur in early operations, the contact of the transplanted bone could not be continued sufficiently long for bone to unite to bone. Dr. Phelps is confident, after viewing the specimen, and taking all conditions and surroundings into account, that bony union would have taken place if actual contact had been maintained for a longer period. The stimulation of the graft, however, has excited a reparative process in the fracture, and it now promises fair to unite. The boy walks with the aid of one crutch, or a cane.

History of the case.—In the month of November, last year, the patient at Charity Hospital was sent to Dr. Phelps for operation. Briefly, the history of the case is this:

The lad, John Gethins, was suffering from an un-united fracture of the lower third of the leg, the result of an operation to remedy an anterior curve of the tibia, which had existed and had slowly increased from early childhood, until he was compelled to go upon crutches.

There was no paralysis of the limb, neither was it atrophied, excepting from non-use; the muscles were perfect in every respect.

A few months after the operation of osteotomy, Dr. Phelps cut down upon the fracture and wired it, but failed in getting union. After a few months he again operated, removing all cicatricial tissue, carefully stitching the periosteum together, and wired the bone. This failed. A few months later he again cut down upon the fracture, removed all cicatricial tissue, and again freshened the ends of the bone, and engrafted decalcified bone chips, according to Senn's method. This failed; the chips came away from the wound a few weeks after the operation. He then resorted to Thomas's method of hammering, damming, and adjusting an appliance for the boy to walk upon. This he wore for several months, but again he failed to secure union. In the mean time the boy had returned to his home.

It seemed a pity to amputate the leg. He had arrived at that stage of the case where, so far as our present knowledge was concerned, amputation was the last and only step to be taken. With all of these facts before him, Dr. Phelps felt justified in attempting any experiment which would promise to succeed in restoring the limb to usefulness, provided the danger to life was not too great.

The brave lad had submitted to every means known to surgery for the relief of his condition, and, discouraged and heart-broken, had returned to his home. When he was told there was another chance for his limb, his face brightened, and he said, "Doctor, I will take that chance." After consulting with the members of the Medical Board, of Charity Hospital, and several eminent surgeons of this city, he decided upon an operation.

It is a well known surgical fact that an amputation performed in the growing limb below the knee, or in the humerus, frequently results in what is known as a conical stump. This necessarily leads to re-amputation, and many amputations have been performed from year to year, in the same case, for this abnormality. This was one of the reasons, but not the greatest, why he hesitated to amputate the limb.

A dog two years old was secured and prepared for the operation, carefully cleansed with soap and water, and made aseptic with a solution of bichloride of mercury.

While the patient was being anæsthetised and the ends of the fractured bones freshened, his assistants, Drs. Plimpton and Mooney, prepared the dog, in the following manner: She was etherized, and then enveloped in a thick layer of absorbent cotton to the thickness of several inches, while placed in the natural sitting posture. Over this soft covering of cotton a few turns of a plaster-of-Paris bandage were made, to hold the dressing in place. The dog was not encased in plaster-of-Paris; the right foreleg of the animal protruded through the dressing. This leg was carefully shaved, and again made aseptic with bichloride of mercury, and finally with ether. The dog was now ready for the operation.

Two elliptical incisions were made down to the fracture, four inches in length, removing the old cicatrix and cicatricial tissue about the ununited ends of the bone, together with an elliptical piece of the soft parts. With a saw the ends of the bones were freshened, leaving a space about one inch between them. The portions removed proved to be eburnated, and more like ivory than bone.

The limb of the patient was now prepared for the next step in the operation, by enveloping it in a plaster-of-Paris bandage, commencing six inches above the incision, and extending to the upper third of the thigh. The foot and ankle were also covered with a plaster-of-Paris bandage. While the surgeons were preparing this part of the dressing, the assistants were preparing the dog. An incision was made through the skin, for the purpose of cutting a piece which would accurately fit the elliptically-shaped wound in the patient's leg. The elbow was now quickly excised; the radius and ulna were severed one-half inch in front of the elbow-joint, and the humerus three inches above it, and removed.

The extremity, near the paw, was amputated, leaving a piece of bone one inch in length, attached to a branch of the brachial artery among the soft parts.

The attachment of the biceps tendon was detached from the bone and loose superfluous muscular tissue removed. In the dog the nutrient artery enters the bone one inch in front of the elbow-joint. Cutting the bone, as indicated above, saved the nutrient artery from injury, and secured the nutrition to the fragment of bone, from which it was hoped that new bone would be thrown out, and at the same time stimulate the human bone to a reparative effort.

The dog was placed by the side of the patient's leg, the head toward the patient.

An aluminum dowel-pin was passed through the medullary cavity in the long axis of the bone. This was though a mistake. A steel pin inserted into the solid portion of the bone would not interfere with the circulation so much. The piece of bone was placed between the ends of the bone of the patient. The bones were crowded together, the dowel-pin entering the bones of the patient above and below. A silver wire was passed around the entire graft, and securely tied. This held the bone securely in place. Muscle was stitched to muscle, and skin to skin, the parts being evenly coaptated. A large drainage tube was inserted for drainage, which opened posteriorly. A few turns of the plaster-of-Paris bandage secured the iron rods to the leg. The wound was dressed antiseptically.

Through the entire operation the most rigid antiseptic methods were carried out. Constant irrigation prevented the possibility of wound infection. The operation can be performed in an hour with efficient dressers. The operation appears difficult and complicated, but is quite simple when understood.

The patients (for we must now say patients) were put to bed. Both recovered from the anæsthetic rapidly. Small doses of morphine were used for both, from time to time, to allay, not so much the pain, as the uneasiness caused by the forced confinement. After three days this uneasiness passed away, and from that time on the dog and patient became friends, administering to each other's comfort—the patient by feeding and playing with the dog, and the dog by vigorous wags of the tail which showed her appreciation of the kindness.

Before the operation was performed the vocal cords of the dog had been carefully severed, under ether, to prevent any disturbance of the patient. At the end of two weeks, however, the cords had again re-united, and the voice of the dog sounded fully as strong as before the operation. The only pain caused to either patient was the twitching of the muscles of the dog as she shrank in her bed from the loss of adipose tissue. This might have been prevented by a simple procedure at the time of operation.

On the sixth day the case was dressed. The wound was found perfectly healed by primary union, without a single drop of pus. Only for the difference in the color of the skin it would have been difficult to detect the line of union. On the eighth day it was again dressed and the union was still perfect and more firm. Finally at the end of eleven days, there was an apparent shrinkage of the dog in the dressings. This allowed of motion, and it became evident that the graft would be pulled from its attachment within a few days. Consequently, as much as it was desired to continue the experiment, Dr. Phelps concluded as an act of humanity to sever the bond of union. He was prepared to do this the moment that he discovered that any surgical interference would become necessary, which would inflict additional pain to either, in order to continue the experiment.

The dog was chloroformed during the operation.

While the graft was being trimmed, and the leg of the patient dressed, the artery was

secured and nicely stitched up the stump of the dog's leg. She was then placed in bed and cared for by the nurse. As the graft was trimmed down to the parts still attached a free oozing of blood took place through the graft, which demonstrated the fact that union had taken place and that circulation had been established between the patient and the dog. Both patients rapidly convalesced. The boy spent his time writing letters to his friends and reading the papers and postal cards from persons praying that the effort to save his leg might not be a failure.

The wound was dressed and the graft examined daily. At the end of five weeks it was discovered that the bone showed no further sign of uniting, and desiring to give the boy every chance for union of the fracture it was removed. The rods, also, were removed, and the ends of the patient's bones placed firmly together, hoping to secure union because of the stimulation produced by the graft. The bone graft was irregularly covered with a new growth of bone, thus proving, he believed, that an effort had been made to unite the fracture.

This was the result of eleven days' contact, whereas at least thirty days are required for bony union to take place.

The canal of the bone was also filled with a new growth of bone, excepting where the dowel-pin passed through.

The average temperature recorded in the patient was about 99½°, in the dog 99 $\frac{4}{10}$. The average pulse of the boy was about 95. The normal temperature of the dog is above a hundred, that of the human being 98½° F. The temperature of the dog fell to below a hundred and that of the boy rose to near a hundred, or the same as that of the dog, where it remained for weeks. The pulse of the boy rose and the dog's fell until they beat nearly the same number of beats per minute, varying from ninety to one hundred and ten. The boy ate, slept, and felt well. There was no sepsis. Whether this peculiar condition of temperature and pulse was due to the interchanging of blood between the animal and the patient, he was unable to say; further observation is necessary to verify it.

After the eleventh day, owing to the plaster-of-Paris accidentally getting into the wound, pus for the first time was seen. This rapidly disappeared.

The operation had a two-fold object: first, to establish the fact that large masses of soft parts could be transplanted from an animal to man; second, to unite an ununited fracture by a section of bone from the dog. It was successful in demonstrating the first proposition, but partially failed in the other in so far as the actual growing of the bone into place is concerned. This was due entirely to a defect in the dressings. The principle of transplantation established means much to humanity; its application will be found useful in many cases which now defy the best efforts of the most skillful surgeons in the world.

Among the cases suitable for the application of the principle are those cases of fractures which resist all efforts for their union, and which must necessarily result in amputation; ulcers of a particular class which can be cured by no means known to surgery. Scalps ripped from the heads of factory girls by machinery. Months and often years have been taken to skin-graft back the scalp to cover the skull, and numerous friends have been flayed to supply the material.

Thiersch's method of skin-grafting has been a step in advance of the older methods, but a martyr must be found to submit to the flaying. A dog would be found better adapted for the work as hair could be transplanted with the flap. Sloughing, following amputations in the upper third of the tibia resulting in cicatricial contraction with indolent granulations covering the end of the stump caused by the bad circulation from pressure are now cured. But how? By amputation at the knee-joint or else so near to it that an artificial limb cannot be worn without a useful knee-joint. Animal transplantation should be resorted to before amputation is performed.

If circulation could be established between opposite species, the elements of whose blood differed, without injury to either, a step would be taken which might lead to the relief of many a sufferer. Then large masses of tissue could be grafted from an animal to man, the circulation of the animal furnishing that which the patient could not supply, as in bone-transplantation. Or in grafting of soft parts the circulation of the dog would keep alive the graft until it had become firmly united to the patient, then it could be severed.

In bone-transplantation it was expected that in four or five weeks the animal would have thrown out a provisional callus and at the same time stimulate the fracture to repair. A dog was selected because the elements of its blood very closely resemble those of man. The reparative energy of a dog is very strong and his power of endurance great. No unnecessary cruelty is inflicted and aside

from the confinement but little suffering occurs. Of course, it is useless to reply to those who have denounced the operation as cruel and unnecessary. Those who understand the motive which actuates the surgeon, can comprehend how, with all sympathy for the brute, his sacrifice of limb may be demanded for the good of his master, man. They, too, can appreciate the reluctance of the surgeon to inflict wanton suffering, whether upon man or brute, and can understand how such an operation only seemed commendable when a more than commensurate benefit was promised. To those whose eyes are blind to human suffering, and whose sympathies are all for the brute, we have nothing to say.

This poor lad personally demanded that every means should be exhausted which promised relief before amputation should be resorted to. He still demands it, and the demand is one which a humane surgeon should consider before resorting to an operation which would involve the loss of a limb and possibly life.

GYNÆCOLOGY.

WHAT EXPERIENCE TEACHES ONE TO UNLEARN.

One of the most respected gynæcologists of this country, Prof. William Goodell, in the *University Medical Magazine*, has recently stated that "every earnest worker in any field of the inexact sciences finds himself compelled to unlearn as well as to learn," and on this basis he communicates a sketch of a number of things, chiefly traditional teachings, which he has himself, in his own experience, learned to unlearn. His summary, of course, relates to the special branch of which he has been a distinguished teacher and practitioner; but many a general practitioner, if he were as honest and candid, could teach his professional brethren similar lessons. Among other things cited by him are the following:

He has learned to unlearn the grandmotherly belief that the climacteric is in itself an entity, and that, as such, it is responsible for most of the ills of matronhood, and especially for that of menorrhagia.

He has learned to unlearn that anteflexion and anteversion in themselves—that is to say, as displacements merely and without narrowing of the uterine canal—are necessarily pathological conditions of the womb.

He has long since abandoned the idea cherished by that class of waistless and witless nurses, now happily obsolescent, that the parturient woman is to be swathed like a mummy and to be kept as immovable.

He expresses his disbelief that mammary abscess comes from "caked" breasts, or from breasts overdistended from a secretion of milk too great for the infant's needs. Mammary abscess, in the suckling woman, comes, in his opinion, from cracked nipples, and from cracked nipples alone.

He has wholly freed himself from the belief that cellulitis is at the bottom of most female ailments, and that the hot-water douche is its cure-all.

He has learned to unlearn the teaching that woman must not be subjected to a surgical operation during her monthly flux. Our forefathers, from time immemorial, have thought and taught that the presence of a menstruating woman would pollute solemn religious rites, would sour milk, spoil the fermentation in wine-vats, and much other mischief in a general way. Influenced by hoary tradition, modern physicians very generally postpone all operative treatment until the flow has ceased. But why this delay, if time is precious and it enters as an important factor in the case?

Long ago he came to the conclusion that the womb, like the nose, has its own secretions; and that, because the cervical canal is stopped up with mucus, it is not to be treated any more harshly than a stopped-up nose. This nasal analogy led him soon to think that even uterine catarrhs are not of such paramount importance as to merit heroic treatment, and that metritis and endometritis, in so far as symptoms are concerned, are often idle words.

He has learned to unlearn the idea—and this was the hardest task of all—that uterine symptoms are not always present in cases of uterine disease; or that, when present, they necessarily come from the uterine disease. Seemingly urgent uterine symptoms may be merely nerve-counterfeits of uterine disease. He has, therefore, long since given up the belief which, with many, amounts to a creed, that the womb is at the bottom of nearly every female ailment. As an outcome of much that he has learned to unlearn, Professor Goodell has arrived at this very short gynæcological creed: "I believe that the physician who recognizes the complexity of woman's nervous organization, and appreciates its tyranny, will touch her well-being at more points and with a keener perception of its wants, than the one who holds the opinion that woman is woman because she has a womb."—*College and Clinical Record.*

ENDOMETRITIS AND ITS TREATMENT.

Dr. Paul F. Mundé, in speaking of a patient having what is known as a chronic endometritis, said that this is not a proper name to give it, because there is no inflammation present. Continuing his remarks he said:

Now, that you may more clearly understand this condition, and the manner in which this discharge is brought about, I will try and explain its mechanism to you in as few words as possible. After confinement the membrane which lines the cavity of the uterus is, as you know, shed, and a fresh mucous membrane is formed beneath it. If this membrane were shed off at once, it would leave underneath it a raw, bleeding surface, which is not mucous membrane at all. This process of shedding is, however, a gradual one, and it takes about two months before a new membrane has been formed and the uterine mucous membrane has returned to the same condition.

The treatment resolves itself into drainage and the application of mild astringents or caustics to the endometrium. I think the tincture of iodine will answer best in this instance, though iodized phenol for a first application might be preferable. In applying this fluid it is necessary to protect the vagina from injury by a pledget of cotton or other material, for carbolic acid or iodine will destroy the epithelium of the vaginal wall.

This application is made by means of a cotton wrapped applicator, which after its introduction into the cavity of the uterus, should be permitted to remain there for a minute or so, for by too rapid a withdrawal of the instrument, you are very apt to tear away the eschar that may have formed as a result of the application. Have your tampons of tannin and iodoform ready, so that you can apply them on withdrawal of the applicator. Instruct your patient to keep quiet the rest of the day, and remove the tampons on the following morning, and use hot douches at a temperature of 110° or 115° F., with the patient in a recumbent position. In about four days you may again repeat this intra-uterine medication, and if you then find that there is little or no oozing, you can conclude that you have done enough cauterization, and apply the compound tincture of iodine in the same way. The latter treatment may have to be kept up for several weeks or months.

There are various other ways in which these applications can be made to the endometrium, besides the one I have just alluded to. The practice of injecting iodine or other fluids by means of a syringe into the uterus is certainly a much more efficient method, but it may prove so very efficient that you will not desire to try it a second time. I have seen uterine colic follow its use, and the uterine colic thus induced, is apt to be so severe as to bring on collapse. There have been cases of death from peritonitis, occurring as a result of this procedure. I therefore, warn you against this method of applying these medicinal agents to the interior of the uterus. Some years ago I devised a fine syringe with a point no larger than a sound, perforated with numerous little holes, with which I made applications to the uterine cavity. I used a weak solution of nitrate of silver for this purpose, but found so much pain followed its employment that I have refrained from resorting to this method for the past four or five years.

Another form of making applications to the interior of the uterus is by means of pencils of gelatine, containing the medicinal agents you wish to employ. There is one great drawback to this procedure and that is the impossibility of obtaining gelatine pencils that remain soft and flexible. I have had a large number of these pencils prepared, but have discovered that in the course of a few weeks they become so hard that they act as irritants, and give rise to severe colic.

Another agent I employ to a great extent for intra-uterine medication is a fifty per cent. solution of chloride of zinc. This is a very effective remedy, but it is necessary to keep the patient in bed after using it. It should be applied but once in ten days, and only a few times in any given case.

The *sine qua non* for intra-uterine applications is a patulous uterine canal, with the external and internal os so wide as to permit the passage of a good-sized applicator, wrapped with a large film of cotton, up to the fundus, if you choose. Of course, in all instances, the removal of the cause of the affection by appropriate remedies, if yon can do so, is the proper course to pursue, whether that cause be pelvic congestion, prolapse, constipation, abdominal plethora or some other condition.

OBSTETRICS.

ANÆSTHETICS IN RELATION TO MIDWIFERY.

W. R. Reid (*Glasgow Medical Journal*).—In the course of a discussion on anæsthetics at the Glasgow Medico-Chirurgical Society, observed that chloroform and ether

were equally valuable for securing thorough anæsthesia in operative midwifery. For the administration of chloroform he preferred a single ply of flannel on a small wire frame used with a drop-bottle. In this way a mild degree of anæsthesia could be readily kept up, and deepened in a minute or two if required. In the case of ether he advocated the use of Clover's inhaler as the only safe plan. He had, indeed, substituted ether by the open method when a patient seemed very weak, and no bad result followed. On the only occasion, however, when he used ether during a lengthened operation the patient was ill for a fortnight afterward with bronchitis and congestion of the lungs. The ether was administered on a sponge in a water-proof cone. Ether had been given in a recent case by Clover's inhaler with perfectly satisfactory results. While he always examined the heart before giving an anæsthetic, yet the knowledge that heart disease existed only made him more anxious to use chloroform or ether, "because in such cases the strain of a severe labor is vastly more dangerous without an anæsthetic than with it. The same holds good with regard to diseases of the kidney." After five-and twenty years' experience of anæsthetics in midwifery cases, Dr. Reid said he had never seen a fatal issue. While his experience of chloroform had been very large, that with ether had been just as limited. "A lying-in woman is peculiarly fitted for escaping the dangers usually connected with anæsthesia. The left ventricle of the heart is considerably hypertrophied, and so less likely to weaken readily in its action. She is kept in the recumbent position, and so, to that extent, defended from syncope. The action of the heart is aided by the alternate relaxation and contractien of the uterus, and, lastly, the anæthesia tends to produce anæmia of the brain, whereas the labor pains give rise to an engorgement of that organ. These causes, taken together, seem to me to account for the great rarity of fatal results in connection with obstetrical anæthesia." He is inclined to believe that there is some truth in the assertion that chloroform may kill a lying-in woman by inducing post-partum hæmorrhage. That danger, however, can be quite set aside by the use of the subcutaneous injection of ergotin and by manual compression of the uterus. He has good reason for believing that chloroform has no danger to the fœtus. He admits it is hard to explain why, with chloroform circulating in the blood of the mother, the fœtus should not run a good deal of risk. He comes to the following conclusions: "1. In severe labor and the ordinary operations I am content to use chloroform in view of its convenience and safety in those circumstances. 2. In long and severe operations, especially where there is much loss of blood, I prefer ether, given by means of Clover's inhaler. This involves more trouble, but its probable greater safety ought to turn the balance in its favor. 3. I hold strongly the belief that while it is advisable to have two medical men present when an anæsthic is given, it would be wrong to enforce this by law.—*Archives of Gynecology.*

THE DIAGNOSIS OF PLACENTA PRÆVIA BY PALPATION.

Spencer reports in detail seven cases of placenta prævia in which he diagnosticated, by abdominal palpation, the presence of the placenta in, or its absence from, the front wall of the lower uterine segment, the diagnosis being subsequently verified by internal examination. The cases were head presentations in multiparæ before pains were present and before the membranes had ruptured; no anæsthetic was used.

In three cases the exact site of the placenta on the front wall of the lower segment was determined; in two cases the placenta was felt when by vaginal examination it could not be found. The absence of the placenta from the anterior wall was diagnosticated in four cases.

The patient should lie on her back for these examinations, the bladder having been emptied; the examination should be gentle, made in the absence of pains, prolonged for several minutes, or repeated, if needed. When the placenta is in front of the head, it is felt as a spongy mass between the fingers and the head. Its edge feels like the segment of a circle, within which the touch is obscured; outside the child is plainly felt. Impulses to the head through the placenta are distinctly felt where the placenta is absent.—*American Journal of Medical Sciences.*

PÆDIATRICS.

THE TREATMENT OF WHOOPING-COUGH.

In a lecture delivered at the Hospital for Sick Children, Paris, Jules Simon (*Journal de Médicine*, 1890, p. 577) remarks that the treatment of the first period is of great importance, for the future progress of the case depends upon the care which is given to it at that time.

One must be well convinced, contrary to the method which was followed formerly, of the necessity of keeping the child indoors; it is often even necessary to keep him in bed as one would do for a serious attack of bronchitis. Archambault has insisted upon the importance of this fact, and since Simon has adopted the same plan he has observed almost no complications in whooping-cough in children who were cared for in time. The pharmaceutical means are not to be neglected, but at best are only secondary; belladonna is, perhaps, the best of all. It is well to employ the following formula: Tincture of aconite root, tincture of belladonna, elixir of paregoric, equal parts—ten, twenty, or thirty drops a day, according to the age of the patient; if there is fever increase the aconite, or if intestinal catarrh increase the paregoric. Chloral may be given in the evening and sulphate of quinine in the morning. These drugs may be used by injection, the former in 15-grain doses, and the sulphate of quinine in three- to five-grain doses, especially if the heart is agitated. We must combat the catarrhal secretions if they are too abundant; under these circumstances an emetic may be given once a week; with the infusion of wild narcissus (daffodil) given every two or three days one obtains a state of mild nausea which favors the expulsion of the secretions; rhatany will also diminish them; of this we may give from three to five grains of the extract before each meal. Coffee is advised, to combat the dyspepsia. The treatment for the third period is that directed to the bronchial adenopathy; it consists principally in the use of tonics, iodine, cod-liver oil, etc., and later, an outdoor life.

To the remedies referred to above, one may add, with advantage, in certain cases, henbane, to combat the meteorism, in doses of from two to ten grains a day, warm friction of the abdomen with chamomile oil, containing tincture of nux vomica, 4 parts to 100, combined with digitalis when there is anuria, a thing that often happens.—*American Journal Medical Science.*

TREATMENT IN CONVULSIONS IN CHILDREN.

In a case of convulsions in a child, if the patient is cyanotic, a few whiffs of amyl nitrite, followed by inhalations of chloroform to relax spasm, should be given. These should be followed as soon as possible by hypodermic injection of tincture of veratrum viride, one-half drop for each year of age up to six years. The veratrum may be repeated in half an hour or an hour, if the convulsions recur. If the convulsions are uræmic, a small dose of morphine may be added or given separately. In all the cases in which I have employed the foregoing treatment the effect was remarkably good, and in but one case have I had to repeat the injection of veratrum. The convulsions cease, the muscles relax, the pulse becomes slower, the temperature falls, and the skin becomes moist. Indeed the danger is over in less time than by any other means I have seen employed. Appropriate after-treatment, as may be indicated, should, of course, be adopted.—*Med. News.*

HYGIENE.

AN ANALYSIS OF THE STATISTICS OF FORTY-ONE THOUSAND, FIVE HUNDRED CASES OF EPIDEMIC INFLUENZA.

Dr. Benjamin Lee, in *The Journal of the American Medical Association*, March 14th, 1891, summarizes the replies of 265 physicians to inquiries made, having a practical bearing on the grippe epidemic of last year, and furnishes some valuable statistics:

People appeared to look forward to the appearance of *la grippe* on this side the ocean as an experience, which, on the whole, would constitute a mild amusement, rather than an occasion of suffering, distress, terror and death. A very few weeks, however, sufficed to convince both the public and the profession that influenza meant a good deal more than a bad cold in the head.

Discovering this fact, and observing the serious involvement of the nervous system in a large percentage of the cases, the inquiry suggested itself to those who were looking for nothing more than a bronchial catarrh, "Is this influenza after all, or is it some other epidemic disease, and if some other, is it not dengue?"

The first point of distinction that we may make is in regard to the mode of extension of the two affections. Influenza, as we have had recent demonstration, spreads like a flood, inundating whole sections in an hour, while dengue works along gradually, establishing centres of infection here and there, enabling its course to be easily traced. In their sudden onset, intense headache, pain in the back and limbs, and excessive lassitude they have much in common, but, while the fever in dengue is invariably of a high grade, in influenza it is often slight or ab-

sent altogether. The catarrhal and pneumonitic complications of influenza, the dyspnœa, the feeble piping voice, are very rare in dengue, while on the other hand, the latter is characterized by violent and persistent gastric disturbances.

An erythematous eruption followed by desquamation, beginning in the face and descending, is rarely absent in dengue, and as rarely seen in influenza. Dengue very rarely terminates fatally, influenza, as we know to our cost, often does. While, therefore, there are points of similarity between the two affections, especially in regard to their nervous pnenomena, the distinctions are sufficiently marked to prevent any misconception, when large numbers of cases are under consideration.

It is probable that not a single individual entirely escaped its pernicious effects. Its manifestations were so various, affecting in one the bronchial tubes, in another the nervous system, now the brain and now the bowels, here peritonitis and there pneumonia, that it was a long time, comparatively, before physicians, even, recognized it in its protean forms. It is scarcely conceivable that a disease which spreads with such astonishing rapidity, goes through the process of re-development in each person infected, and is only communicated from person to person or by infected articles. And yet this theory has been maintained by a few authorities who claim that it is always more prevalent along lines of travel, and that it did not progress more rapidly than modern means of communication would enable it to do.

The following is an analysis of the results obtained:

Number of physicians reporting,	265
Number of cases,	37,275
Adults,	26,302
Children,	10,973
Number of cases nervous,	6,913
Number of cases catarrhal,	16,434
Number of cases inflammatory,	5,829
No. of deaths directly caused, 56 No. of deaths indirectly caused, 205	261
Immediate cause of death, bronchitis,	8
" " " pneumonia,	117
" " " phthisis,	42
" " " nervous,	21

Supposing, which there is no reason to doubt, that the 265 physicians who replied, represent a fair average of the practitioners of the State, this would give us 1,120,000 persons as having been sufficiently ill with the disease to demand medical aid or come beneath the observation of a medical man, and 7,879 deaths directly or indirectly caused by the epidemic influence in the State of Pennsylvania alone. We know that there were many who suffered mild attacks who never sought advice, and many more whom physicians, in their excessive haste, failed to enter on their visiting lists although they may have prescribed for them.

In fact this is exactly the return that was made in some instances:

"Treated an immense number of cases but kept no record."

Nearly one-half of the cases reported were in the city of Philadelphia. As the Philadelphia physicians reporting constituted only about one-third of the whole number, the disease must therefore have been more prevalent in large cities than in the country. To be exact, the average of cases to each physician reporting was 140; while the average to each Philadelphia physician reporting, was 193.

The disease seems to have been especially prevalent in mining towns. Two physicians in Shamokin, a place of about 12,000 inhabitants, report 950 cases between them. In Greensburg, a place of about 6,000 inhabitants, two physicians report 737 cases. In the little village of Portage, Cambria County, numbering 650 inhabitants, one physician reports 400 cases. Ill-fated Plymouth suffered seriously as did the most of the other mining towns and villages of Luzerne County. Scranton was also severely visited.

One curious fact developed by the investigation is that the disease was observed quite as early in the extreme western portion of the State as in Philadelphia on the eastern border. Indeed, more observers in proportion to the population report having observed cases in November in Allegheny County than in Philadelphia County: as though a disease-bearing air current had passed over the eastern border at a great altitude and dipped down in the western portion of the State.

Of the 265 physicians reporting 206 made the distinction as to the predominant type of the disease. While it is to be regretted that all did not, still this number, representing more than 29,000 cases, is ample for purposes of deduction.

Nearly 7,000 of these are recorded as belonging to the nervous type. This is very nearly 25 per cent. and does not, of course, preclude the presence of nervous symptoms in a large proportion of those set down as catarrhal or inflammatory. And this takes us back to the point from which we started, namely the marked predominance of the

nervous element and the protean character of the manifestations in this singular affection. How shall we account for the production of such varied morbid phenomena by a single morbific agent?

To the writer, the most probable explanation is, that the morbific influence, whether germ, microbe or occult meteorological departure from the normal condition, spent itself directly upon the nervous system, and more particularly on the vegetative portion of that system, or to particularize, still further upon the pneumogastric nerve and its associated ganglia with partial implication of the spinal cord. Nearly all phenomena which distinguish influenza from other similar affections can be readily accounted for by this theory; the excessive nervous prostration, so entirely out of proportion to the catarrhal disturbance, the emotional depression, causing the victim to weep incessantly without consciousness of any reason for so doing, the sense of constriction about the larynx, the strident cough, piping voice and occasional aphonia, the sudden congestions of the lungs, the pain and stiffness in the dorsal muscles, especially along the nucha, the gastric and intestinal disturbances, the intense headache, and transient manias, all can be accounted for by the supposition that the great balance wheel of organic life has become deranged—and on no other theory so simply.

The fact that all the remedies which were found most beneficial in the treatment of this affection are nervines, such as phenacetine, morphia and nux vomica may also be adduced as strongly confirmatory of this theory.

MODE OF ENTRY OF THE TUBERCULAR POISON INTO THE BODY.

Dr. Bollinger believes that the frequency of infection through the skin has been underestimated. Several cases have been recorded of direct inoculation by wounds received from broken spittoons, by bites, operations, earrings, etc. Eczema and impetigo increase the susceptibility of the skin. No case has as yet been attributed to vaccination, and it would appear that the tubercle bacilli are unable to live in the vaccine lymph. They also appear unable to pierce the pores of the skin as do some of the pyogenic organisms. The susceptibility of the mucous membranes is increased by inflammatory processes, such as otitis, rhinitis, conjunctivitis, and pharyngitis. The poison travels to the submaxillary glands and those of the neck, and generally causes local tuberculosis of the glands. The chief point of infection is of course the lungs. Local predisposition is best exhibited by apices which have been before diseased, but have undergone a healing process. The movement is deficient both in expiration and inspiration, and the liability to reinfection is increased by anæmia, irritants, constitutional influences, such as diabetes, disturbances of digestion, and unhealthy surroundings generally. The poison may pass through the lungs and attack the bronchial glands, under which circumstances the disease may be very insidious. The predisposition of the lungs again exhibits itself in metastasis; not every tubercular disease of these organs is due to inhalation of the bacilli or their spores. As regards primary tuberculosis of the testicles, joints, and bones, Bollinger considers that a latent hæmatogenic infection must be understood, which leaves as little trace of its point of entry as does a primary septic endocarditis or an osteomyelitis. Tubercular disease of the larynx depends upon an auto-infection through the sputum. The rarity of this disease in children is explained by the infrequency of pulmonary cavities in the rapid forms of phthisis. Primary tuberculosis of the intestine generally, combined with an affection of the mesenteric and retroperitoneal glands, is usually occasioned by means of vitiated food and contaminated feeding utensils. Secondary tuberculosis of the intestine depends upon an auto-infection. The tubercular poison passes through to the intestine unaltered by the juices of the stomach and attacks the Peyer's patches and solitary follicles. Tuberculosis of the peritoneum, which is three or four times as common in men as in women, can arise directly from ulcers of the intestines, from tubercular abdominal glands, or, especially in women, from the urogenital tract; further, through contagion from the lungs and pleura, and finally in the course of miliary tuberculosis, or from caseus bronchial glands. Primary tuberculosis of the peritoneum is quite rare. As regards the infection from milk, this is, in Bollinger's opinion, undoubtedly due to the udder of the cow being affected with the disease. Infection through the milk of tuberculous women has not yet been proved. *Münchener Medizinische Wochenschrift.*

REGULATION OF PROSTITUTION.

Moeller in the *Journal des Maladies Cutanées*, December, 1890, makes the asser-

tion that the measures adopted in the regulation of prostitution are inefficient from a hygienic point of view. While admitting that the danger of contagion is greatest during the primary stage of syphilis, and slightly less during the secondary period when the external manifestations of the disease are present, he claims that during the entire secondary period the person infected is able to transmit the disease, even when there are no external manifestations, as has been proved by the infection of nurses from infants and *vice versa*, and by the infection of women during intercourse. This contagiousness of syphilis during the latent stage of the secondary period, is but little marked if the body of the infected person does not present any external solution of continuity; but the slightest scratch or laceration of the skin or mucous membrane considerably increases the danger of contagion. For this reason Moeller claims that persons afflicted with syphilis should abstain from sexual intercourse not only during the existence of the primary sore, or when the secondary manifestations are present, but in the latent period as well. This is the duty of every man or woman affected with syphilis, to neglect which is culpable. He goes on to say that our present regulations are based upon the assumptions of physicians at the beginning of this century, who believed that gonorrhœa, soft chancre, and syphilis, were all of the same nature, and only contagious in the initial stages. The researches of the succeeding years have entirely revolutionized these views, hence the necessity of altering the laws governing prostitution to meet the dangers which have been discovered.

As a substitute for the present laws upon the subject he suggests a system as follows: Every person who is convicted of certain offenses relative to prostitution, or who has committed some infraction of the articles of the penal code, should be, if he be sentenced to imprisonment, submitted to a physical examination at the moment of arrest. This examination should be repeated at the expiration of punishment. If the physician confirms the presence of syphilitic lesions, the patients should be admitted into a hospital for treatment. In addition, they should be forbidden to resume their trade, and instructed not to indulge in sexual intercourse as long as the dangers of contagion exist. They should likewise be obliged to submit to periodical visits during a variable time, to be determined at the beginning of the sickness. The advantage which Moeller claims for this system is, in the first place, the suppression of the registration of prostitutes; second, in place of leaving to hazard or to arbitrary attention the designating of the prostitutes who should be submitted to sanitary visits, it is the prostitutes who, by the infractions they have committed, would designate themselves, in virtue of a positive law which they know and which they ought to recognize. Moreover, the civil authorities would no longer recognize the right of the infected prostitutes to continue their business, and would interdict them from the practice of their profession, so long as they could be dangerous to the public health. Thus would disappear that security which the public accords, rightly or wrongly, to the registered prostitutes, who are considered as healthy in virtue of the certificate delivered after the inspector's visit. Finally, the prophylactic system thus designed would neither violate individual liberty nor the moral law.

MEDICAL CHEMISTRY.

CHEMICAL REACTIONS OF KOCH'S TUBERCULIN.

In the *Farmatzevtitchesky Jürnal*, No. 9, 1891, p. 136, Mr. I. Gertel, a chemist, publishes the result of his examination of a specimen of Koch's "tuberculin." The "lymph" forms a cinnamon-brown, odorless, viscid fluid, sp. gravity of 1.17 and of a neutral reaction. Concentrated sulphuric acid dissolves it easily and completely, the solution being at first colorless, but after a while assuming a cinnamon-brown color. Concentrated hydrochloric acid does not manifest any action on the lymph, while concentrated nitric acid produces a slight opacity, appearing at the point of contact between the two fluids. When immersed in a sulphuric acid solution of tuberculin, crystals of bichromate of potassium soon become covered with bubbles (which are due to glycerine being present in the preparation). The following reagents give considerable precipitates on being added to a 10 per cent. aqueous solution of tuberculin: Tannic acid, picric acid, chloride of gold, nitrate of silver, sulphate of copper, nitrate of mercuric suboxide; but chloride of platinum, neutral acetate of lead, and chloride of tin, produce a comparatively slight precipitation; iodide of potassium and cadimum (double salt) give a distinct turbidity, but no actual deposit. The following substances behave entirely negatively toward the solution: Iodide of potassium

and mercury (double salt), bi-iodide of potassium, chloride of iron, ferro-cyanide of potassium, chloride of mercury, molibdenate of ammonia, rhodanide of potassium, chromate of potassium, ammonia, and sulphate of iron. When heated with acids, the aqueous solution assumes an intense yellow color. Strongly diluted aqueous solutions give voluminous precipitates with alcohol, the deposits being re-dissolved on a free addition of water. A 10 per cent. aqueous solution, as well as more diluted ones, when kept at the ordinary room temperature, becomes turbid even on the next day. As to the lymph itself (that is, an undiluted preparation), it has not undergone any changes even after 4 months' keeping.

THE DA COSTA LABORATORY OF BIOLOGY.

It is announced that the trustees of Columbia College have determined to devote the late Mr. Charles M. Da Costa's bequest of $100,000 to the foundation endowment of a laboratory of biology, to be built on the grounds of the medical school (the College of Physicians and Surgeons), and that the professor in charge of the department is to be designated the Da Costa professor of biology. This is an early and striking manifestation of the good likely to result from the union of the College of Physicians and Surgeons with Columbia College.

THE PHONOGRAPH OF MEDICINE.

The applicability of the phonograph to the record and demonstration of defects in speech has been well illustrated during the past week at the Royal Medical and Chirurgical Society and at the Hunterian Society. At the first named, Dr. Hale White and Mr. Golding-Bird were enabled by means of this instrument to allow the Fellows present to hear the curiously defective speech of two children, and to contrast this with the improvement effected by treatment, for the subjects were present, and after the phonograph had given their past utterances, their present speech was demonstrated *vivâ voce*. The papers read by the above gentlemen and that by Dr. F. Taylor led to an instructive debate, which was further illustrated by some marked cases introduced by Dr. Hadden. The outcome seemed to be that these defects in articulation are probably of central origin, and not due to any mechanical interference with the organs of speech. Whether, as suggested by Dr. Langdon Down and Mr. Spencer Watson's the defect was primarily one of audition it is a question certainly worthy of consideration. Another point raised was whether the defect should be considered one of speech or language, and some exception was taken by Dr. Taylor, Dr. Pye-Smith, and others, to the use of the term "idioglossia," which, however, was ably defended by Dr. Hale White. The other phonographic demonstration at the Hunterian Society was by Dr. Hughlings Jackson, who thus reproduced the characteristic speech of a subject of cerebro-spinal sclerosis. There can be little question that the phonograph will ultimately prove very useful, especially in the preservation of certain anomalies of articulation, and its further extension to other sound phenomena in the range of clinical medicine may be justifiably hoped for.—*Lancet.*

NEWS AND MISCELLANY.

We are authorized to state that Dr. J. M. DaCosta is not going to Europe this year as reported.

Dr. J. M. Baldy has been elected Professor of Gynæcology in the Philadelphia Polyclinic and College for Graduates in Medicine.

The twenty-sixth annual meeting of the members of the Michigan State Medical Society, will he held in Saginaw, Thursday and Friday, June 11th and 12th, 1891, at Germania Hall, a building so situated as to be readily reached from all principal hotels by electric cars, and sufficiently commodious to accommodate the work of the General Sessions, the Committees and all of the Sections.

The President's Annual Address will be given by Dr. L. W. Bliss, Saginaw; subject to be announced later.

The Address of the Orator appointed by the Section on the Practice of Medicine, will be delivered by Dr. Heneage Gibbes, Ann Arbor, subject, "Phthisis."

The Orator appointed by the Section on Obstetrics and Gynæcology, is Dr. J. H. Kellogg, Battle Creek, and the subject of his address will be: "The Influence of Dress in Producing the Physical Decadence of American Women." This address will be appropriately illustrated by stereopticon views.

Dr. H. O. Walker, Detroit, will give the address on Surgery; subject to be announced later.

The Medical Society of the State of North Carolina, will meet at Asheville, May 26th, 27th and 28th, 1891.

Clinical Lecture.

LEG ULCER—SKIN GRAFTING—KELOID—LUPUS—DIFFERENTIAL DIAGNOSIS OF LUPUS AND EPITHELIOMA—SCROFULOUS ULCERATION OF THE CERVICAL GLANDS—TRAUMATIC INFECTION—ANTISEPTIC POULTICE.

BY ERNEST LAPLACE, M. D.,

PROFESSOR OF PATHOLGOY AND CLINICAL SURGERY, MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA; SURGEON TO THE PHILADELPHIA HOSPITAL.

LEG ULCER.

Gentlemen:—The first case that I bring before you to-day is one that was operated upon by me eighteen days ago, and affords an excellent example of the successful results obtainable by the modern surgical method followed in the treatment of these cases.

A leg ulcer is a necrosis of the epithelium and underlying tissues. The surrounding parts are indurated and inflamed, and the edges of the ulcer are hard and callous. Of itself, a leg ulcer will not heal, but continues to increasei n size, until it frequently reaches entirely around the limb.

The treatment to be followed is, therefore, to cover this denuded and ulcerated surface with new skin; but before attempting this, we must prepare the surface of the wound for its reception. So the first step is to scrape away the necrosed epithelium and remove the callous edges. This must be thoroughly done, and it matters not if the operator goes right down to the muscle, or at all events until healthy and living tissue is reached. Then leave the wound until healthy granulations have begun to form, and you have a surface ready for your skin graft. Even this preliminary operation should be conducted with strictest aseptic precautions.

SKIN GRAFTING.

Let us turn aside from this patient for a moment to review the question of skin grafting. The process is a comparatively new one in surgery, dating only a few years back; but when skin grafting was first successfully performed, it was thought that only minute grafts could be transplanted. Accordingly, it was then the practice to snip off a tiny piece of skin, no larger than a pin's head, and to cover the denuded parts with a number of these. Such little grafts would form islands of epithelium which gradually increased in size, and joined one another, until finally the whole surface was covered. It was argued, however, that if a small graft would take root and grow, a large one should do the same, all things being equal. The total immunity from suppuration afforded by modern aseptic surgery, has enabled us to prove that this is truly the case. We no longer transplant minute fragments of skin, but take strips, or pieces, large enough to cover the entire denuded surface at the outset. This is what has been done in the case before you.

Let us first examine the spot from whence I took the skin. You see that it is entirely healed, and covered with new epithelium, although a large amount was removed. A valuable lesson may be learned from this. In no case should we hesitate to take from a healthy surface all the epithelium we need, for if we proceed aseptically, new epithelium is rapidly formed, and the healing is perfect. You will notice that the new skin covering is redder than the surrounding skin; this is because, first, it is thinner, and second, because the blood vessels lie nearer the surface. Ultimately, however, this new skin will become thicker than that of the surrounding parts, owing to the friction and irritation caused by the clothing, and a similar process of epithelial thickening will take place as that which occurs on the hands of rowers, where friction primarily wears away the skin, but where finally additional epithelial cells are thrown off until the part becomes materially thickened. Eventually, this reddened skin, now tender and thin, will, therefore, become thick, and also of a

darker color than the surrounding parts.

We will now turn our attention to what eighteen days ago was a very ugly looking indolent ulcer. You see that its surface is entirely covered with exceedingly delicate epithelium, so thin indeed as to be transparent, enabling us to see the underlying granulations. The operation has been a success, and nothing further remains to be done than to keep the part protected with an antiseptic dressing, and to keep the man in bed until this new epithelium has become thick and strong.

Right here let me warn you against a needless fear, often experienced by the young surgeon in similar cases. When, a week after having made the graft, you remove the dressing, you will find a large slough of dead epithelium come away with it, and you will very naturally conclude that the graft has not taken and that your operation has been a failure. Not so, however, for below the dead epithelium you will see the thin and transparent membrane which we have here. This is easily explained. In grafting we can only expect epithelium that is alive and well nourished to grow upon the denuded surface. Let me remind you of the anatomy of the skin. The uppermost layer, the horny epithelium, is dead, and comes off in washing as dandruff; below this are epithelial cells also poorly nourished; below these are the papillæ with their blood vessels and surrounded by living epithelial cells; and, finally, below all these is the fibrous tissue. In taking our graft we cut through these papillæ. We know this because we have distinct hemorrhage. This living and well-nourished epithelium we graft on our denuded surface where it grows and new epithelial cells quickly form from around the papillæ and push up the layers of unnourished cells, so that when the dressing is removed it would seem as though the whole graft had come away, while in reality the living epithelium has taken root.

KELOID.

The next patient which I will call your attention to this morning, is also one that was operated upon about two weeks ago, and is another example of successful skin grafting.

A keloid is, as you know, a dense cicatricial formation, which causes considerable contraction. This man came to the hospital with a dense growth on the ball of the thumb, which contracted that member into the hand. The growth was primarily removed, and a week allowed for healthy granulations to form over the denuded muscles, for both the adductor and flexor pollicis were laid bare. We then grafted, covering the entire surface with new epithelium, and with the gratifying results which you now see. The man's thumb is in a normal position. To be sure, we had far greater chance for success than in the case of leg ulcer, for there we were dealing with necrosed and diseased tissues, while here the parts were healthy and well nourished.

Look at the man's fingers. You will remember that these also were greatly contracted but are now nearly straight. It is the tendency of these contractions to increase, as additional deposits of cicatrical tissue are formed about the tendon, until finally a useless hand is the result.

What was done in this case, was to cut down upon the tendons, and nearly through them, severing fully three-fourths of their substance. The remaining fibres acting as a suture to keep the ends in apposition. The fingers were then stretched until straight, and put on splints. The stretched tendons gradually became strengthened and the gaping cuts in them healed up, the fingers remaining straight.

LUPUS.

The next patient is a man suffering from lupus who has been treated with Koch's lymph. One milligramme of the lymph was injected on Monday, two milligrammes on Tuesday, and three on Wednesday—none since (Saturday). The improvement has been very marked, and healing has already begun to take place.

I am not prepared to make any definite statement regarding the value of Koch's lymph, but am free to acknowledge that its action upon local tuberculous processes—and lupus is one of these—is undeniable. What will be the result of this treatment I cannot now say. The man may make a complete recovery, as I have seen many such follow the use of Koch's lymph; the disease may, however, return after a time. Time alone will decide the case.

The principal reason for my bringing this case before you was in order to demonstrate differential diagnosis between it and a case of epithelioma.

DIFFERENT DIAGNOSIS OF LUPUS AND EPITHELIOMA.

Let us first study their similarity. Both have ulcerating surfaces, and in both the skin slopes down toward the ulcer, and their general appearance is not at all unlike. You will notice, however, that the surrounding

skin, in the case of epithelioma, is indurated and hardened, while in the case of lupus the skin is freely movable over the surface of the granulations. Often, indeed, a narrow bridge of skin will stretch across the ulcerating surface. This feature is peculiar to tuberculous ulcerations. In tuberculous processes also, the granulations extend under the skin, while in epithelioma the skin is destroyed as far as the ulceration reaches.

Under the microscope the difference is still more marked. In the granulations taken from a case of lupus we find round cells with a nucleus, these are tubercular cells. Often also we find much larger cells, containing three or more nuclei, these are known as the giant cells of tuberculosis. Their existence is due to the fact that the formation of the nuclei occurs more rapidly than the segmentation of the surrounding protoplasm.

In epithelioma the microscope shows a totally different picture. Before us lie myriads of epithelial cells of all shapes and forms.

The most definite and perhaps practical means for the differential diagnosis of lupus and epithelioma is afforded us by Koch's lymph. For it invariably causes a re-action in all cases of local tuberculosis, while it has absolutely no effect in cases of epithelioma. This fact alone is sufficient to make for Koch's discovery a permanent place in medicine.

SCROFULOUS ULCERATION OF CERVICAL GLANDS.

The child that lies before you presents another, and a typical form of local tuberculosis. It is a very ill child, and its condition demands immediate attention. In the neck, over the region of the cervical lymphatic glands, is a large dense tumor—very large for a child who has not seen more than two summers. Near the angle of the jaw the growth has ulcerated, and a cheesy matter is discharged from the opening. We see, also, that the opening is bridged by a narrow strip of skin, and this fact gives us an immediate clue to the diagnosis, as you remember I referred to this peculiarity as being typical to tuberculous ulcerations. We find that the mass is slightly movable and from its appearance and location, are forced to the conclusion that the growth is a scrofulous ulceration of the cervical glands. This conclusion is strengthened by an examination of the patient's temperature chart, which shows a very high evening temperature. The case, therefore, demands the immediate removal of these glands, and were it not for the fact that the parents' consent to the operation has not yet been obtained, I would perform it to-day, but will be forced to delay it. In the mean time every effort will be made to improve the child's physical condition, so that it will be better able to stand the operation.

It is in these fair-skinned, blue-eyed children that we generally find scrofula. In all probability in this case other glands are also affected.

TRAUMATIC INFECTION.

The last patient which I shall have the pleasure of showing you to-day, is this man who came to us, not long ago, to be treated for a very painful tumor over the glands in the neck. The growth is not clearly defined, but of irregular shape and very painful; the surrounding skin is also inflamed and painful. We evidently have an acute inflammatory process here and must look further for the cause. We find that a short time previously he had received a contused and lacerated wound of the scalp by being struck with a rock, but to which he had paid little attention.

All wounds if improperly dressed or treated are liable to infection, but contused and lacerated wounds, where a large amount of tissue is destroyed, are peculiarly so disposed, the wide-open mouths of the lymphatics being always ready to imbibe the poisonous germs.

Let me here tell you that nine-tenths of all acute inflammatory processes are caused by the pus microbe, the *streptococcus pyogenes aureus*, and it is an infection from this source that we have before us.

Never, gentlemen, never be tempted or led to apply a hot poultice to such an inflammatory process. What could be more conducive to the propagation of these poisonous germs than the application of heat and moisture! What season of the year so fruitful of infectious diseases as the hot and wet months of summer? To apply a hot poultice to such an inflammation is to court further infection, when the real object in view is to retard it. What is demanded is, first, an opening up and cleansing of the wound, which has been the door to the infection, and the removal from it of any infectious matter; it should then be dressed aseptically. Next, local applications to the point of infection, of such a nature as will check the suppurative process and cause the death of the microbe. For this purpose antiseptic solutions are alone available. *Wet*, if you like, gentlemen, but never *hot*.

ANTISEPTIC POULTICE.

Take a solution of 1 : 3000 of corrosive sublimate, or better still, an acid solution of 1 : 3000 of the same, as it is stronger, and make a cold poultice with linseed meal, for the meal will hold the moisture better and longer than any cloth, and apply this over the seat of inflammation, and the suppurative process will soon cease, and the pain and swelling disappear.

The modern poultice is an antiseptic poultice.

This is the bent of modern surgery, the prevention of infection, and the maintenance of aseptic cleanliness. By these means we may cope with ulcerations on the surface, and check the process of inflammation even when hidden deep in the tissues. These are lessons worthy of your careful consideration and earnest study.

ACUTE PARENCHYMATOUS NEPHRITIS, WITH ACTIVE PULMONARY CONGESTION.

BY PROF. CHAS. G. STOCKTON.

BUFFALO GENERAL HOSPITAL.

Gentlemen :—The history of this patient is as follows : Aged 42, married, Canadian, carpenter. Family history negative. The patient had measles and scarlet fever when a child, apart from this he has always been well and he denies any venereal trouble. On Wednesday, a week ago to-day, while at work, he was taken suddenly with a severe chill, followed by fever and nausea, but he has vomited only two or three times. The attacks were also attended by considerable headache, which has continued with intermissions up to the present. He stopped work, went home and to bed, and he has been in bed most of the time since. He has no appetite and the nausea has continued. Since Thursday he has had griping pain in the abdomen, and diarrhœa existed from Thursday until Monday. On Sunday he had a second chill. The patient is a moderate drinker and he smokes to excess. On entering the hospital his pulse was 98, temperature 103.4°, respirations 38.

The patient, as you look at him, will impress you at once by his appearance of apathy. The man is evidently very sick, very feeble, and somewhat cyanosed. His breathing is between 40 and 50 a minute, his pulse has varied between 100 and 110, and his temperature between 103.5° and 104.5° since his admission. With these symptoms and from the man's appearance, we would say that there was something wrong with his respiratory apparatus, and, to follow the symptoms up more carefully, we find that he has a moderate cough and considerable expectoration of muco-purulent matter which is very tenacious, and which sticks to the bottom of the cup and looks like the expectoration of catarrhal pneumonia. In all probability the prostration and apathy depend either upon the severity of the fever, or upon some toxæmia, or the two combined. The toxæmia may arise from his lung trouble or from some other condition.

The tongue, which he protrudes slowly, is dry, brown and cracked. He says his hearing is good, but you observe that he understands slowly, giving one the impression, at first, that he is deaf. The condition of the tongue and the slow cerebration are evidences of a toxæmia.

As we inspect his breathing, we find it rather shallow, but symmetrical. He breathes as though his lungs were not properly filled with air and as though the bases were particularly involved. This condition might come about from inflammation of the lung and the exudation of fluid into the substance of the lung, from effusion around the lung, or merely from congestion of the lung. I find everywhere, anteriorly, a feeble respiratory murmur, with harsh sounds and some so-called dry râles in the upper part, some moist râles and a few sibilant sounds lower down. The vesicular respiration is harsh, superficial and very imperfect. The same condition is found behind, the breathing is particularly obscure and impure at the bases. The breathing behind is accompanied by more sounds of disease, such as râles and sibilant breathing, than in front. I regard the evidences, so far as the lungs are concerned, both from the history of the case and the physical examination, to be in favor of congestion of a high degree with a certain amount of inflammatory trouble in the bronchial tubes, the amount of actual inflammation being much less than we would expect to find with the rapid breathing, high temperature, frequent pulse and the general prostration of the patient. I do not find enough trouble in the chest to account for the general condition and that was what impressed the house-staff when they first saw the man.

While the pulse is somewhat ample, it is very feeble, and still it has more resistance

and greater tension than we would expect in typhoid fever with this temperature. On examining the abdomen to make sure that we are right in excluding typhoid fever, we find it slightly distended with gas. The skin looks normal, there is no eruption, and pressure over the abdomen discovers no points of especial tenderness. There is little evidence of abdominal trouble and the bowels have moved regularly since the diarrhœa. Last night he was given epsom salts and, as a result, he had three or four large involuntary stools, not typhoidal, but of a light yellow color and with a distinct odor of urine. He has passed three pints and a half of urine in the last twenty-four hours. Two days ago there was a very slight discharge of condensed urine, yellowish red, very acid, containing a large amount of albumen. The sediment contained a large quantity of débris, renal epithelium in abundance, and granular blood and epithelial casts. The blood casts were conspicuous by their abundance. There were no fatty nor hyaline casts.

Now let us look at the case from the standpoint of the information derived from the examination of the urine. Here is a man apparently in good health, suddenly seized with chill, fever, prostration, vomiting; who has been confined to bed for a week, at the end of which time we find him still very much prostrated, with a frequent feeble pulse, high temperature and brown cracked tongue, with scanty urine, and with evidence of lung trouble. Which of these two conditions: the nephritis or the congestion of the lungs, was primary? It is not common for an acute lung trouble to cause an acute nephritis, but it is quite common to have congestion of the lungs and a certain amount of disturbance of respiration with acute nephritis. The evidence points, therefore, toward the conclusion that this man was seized with an acute nephritis at the time of the initial chill.

If we had not examined the urine we should say that the man was seized with an acute lobular pneumonia, and from the high temperature and prostration we would make a grave prognosis; but knowing the condition of the urine and having an explanation of these symptoms of prostration, the prognosis becomes better though still guarded. From the examination of the urine we would conclude that this is a case not of chronic but acute Bright's disease, from which recovery is to be expected. The lung trouble is somewhat secondary to the kidney lesion. I say "somewhat secondary" because at the same time that he caught cold and the nephritis started, the lungs might have become involved. But the blood going to the lungs is loaded with excrementitious products which have irritated the pulmonary tissue, and the condition of the circulation is depressed and the pulse frequent. This case would probably result fatally from the condition in the lungs being maintained by the disease in the kidneys if the latter organs were not properly attended to.

The cause of this attack we do not know satisfactorily. There is no history of falling into cold water or other marked exposure. The measles and scarlet fever occurred too long ago to have any causal relation. They might have been followed by a nephritis which has become chronic and has been lighted up into an acute exacerbation, but the condition of the urine as reported to me does not indicate the existence of such a condition. The heart is apparently sound, though excited in its action, there is no evidence of previous cardiac valvular lesion nor of acute endo-carditis. Although we cannot account definitely for this nephritis, we must remember that it is not uncommon to have an acute Bright's disease coming on without any special exposure, just as on the other hand, exposure to wet and cold is not always followed by this trouble.

It is important that a case like this shall receive early treatment. I directed that the patient's back be thoroughly cupped, that his feet be bathed in hot water, and, that he have hot vapor baths. As a result of the treatment the sweating was induced and the amount of urine passed increased very largely. In proportion as the elimination by the kidneys increases his symptoms will subside. He was also cupped over the lungs and the essential oil of camphor was used as a stimulant application. I did not use turpentine because it is a stimulant to the kidney and a kidney already overstimulated by inflammation should not be exposed to the danger of further irritation. The treatment was directed principally to the skin, both to aid elimination by exciting sweating and to relieve the kidneys of their engorgement by bringing the blood to the surface. Magnesium sulphate was also given to carry off the poison by the bowels and to relieve the circulation by depletion. A light diet was ordered, the nervous symptoms were controlled by bromide of potassium, assisted by moderate doses of chloral. Internal medication directed to the kidneys is to be avoided in such a case as this, although it would be perfectly safe to give potassium acetate or

sodium benzoate, which are un-irritating diuretics. The former is especially indicated when the urine is highly acid, the latter usually increases the acidity of the urine, but it may often be given with benefit even in cases of acid urine. Potassium acetate should be given in doses of fifteen grains once in two hours with infusion of digitalis. Sodium benzoate is given in five grain doses every two hours with or without the digitalis. Digitalis is given with a view to increasing the pressure of blood in the kidney.

This is the only medication which I think should be directed toward the kidneys themselves when they are acutely inflamed or acutely irritated. The purgatives act indirectly on the kidneys in the most favorable way possible, lessening their labor of excretion and removing the effete products which would otherwise accumulate in the blood. The necessity of examining the urine, especially in cases like this of congestion of the lungs, is the most important lesson to be learned from this case.

CLINIC THREE DAYS LATER.

These are specimens taken from the patient whom you saw on Wednesday. His urine was increased in quantity and the condition of his kidneys improved until they were functionally fairly well, but, contrary to my expectations, the man did not improve under the treatment that should have unloaded the venous side of his circulation, he grew weaker, suffered more and more from dyspnœa, and finally died by failure of respiration.

The post-mortem revealed, as the physical examination two days before had promised, a very acute congestion of the lungs. The right lung showed rather more infiltration than could be classed under the head of congestion, there was very complete œdema, particularly of the lower lobe. The upper portion of the right lung and the left lung were markedly congested. The lung now crepitates very feebly and is still dark in color, though it has bleached out somewhat since the autopsy.

The examination further revealed that the kidneys, instead of being healthy previously to this acute attack, as I supposed from the history of the case and the report of the urine analysis, had been for a long time diseased, the man having the so-called large white kidney—the chronic parenchymatous form of diffuse nephritis. There was an acute attack which was superadded to the chronic kidney trouble. These kidneys did not appear red and congested as other organs of the body did, and you see now how pale they look. But if you examine them carefully, you will find injected points lying among large masses of comparatively white tissue. These are not the red engorged kidneys which I expected to find. Does this mean that the man did not have the acute inflammation which I described to you? Not at all, it means that the kidneys were congested like the other organs of the body, but they were pale because their tissues had become so changed by chronic disease, which I did not suspect because the report of the urine analysis misled me—that the areas remaining for blood to enter were small. These kidneys were red and congested for such kidneys, but yet they contained far less blood than is normal. It is precisely what we expected to find, but occurring in the midst of another change.

The heart was somewhat enlarged but there was no valvular lesion. On account of the swollen condition of the lungs, this enlargement was not manifest at the physical examination. Although the predominating inflammation in the kidney was parenchymatous, yet there was some fibroid change which would cause resistance to the onward flow of the blood and thus produce hypertrophy of the heart. There were a few atheromatous markings just above the cusps of the aortic valves.

The spleen and liver were congested. The stomach was large but empty, and held nine pints of water. The great majority of cases of dilatation of the stomach, occur in those who have no stenosis in the alimentary canal, and there was no stenosis here. Stenosis below the stomach, however is quite apt to be a mechanical cause of such a dilatation.

COMMUNICATIONS.

CANCER OF THE RECTUM.[1]

BY L. L. McARTHUR, M. D.
CHICAGO, ILL.

In my brief experience as a surgeon it has been my fortune to number among my cases six examples of this disease in various stages of advancement, as follows: one, female, cancer within two inches of anus, colostomy and excision; one, female, cancer involving anus and lower rectum, colostomy, excision; one, female, cancer involving

[1] Read before the Chicago Gynecological Society, January 16th, 1891.

anus and rectum, colostomy, no excision; one, female, cancer high in rectum, no colostomy, curettage; one, male, Kraske's operation, colostomy (Dr. Fenger's case); one, male, no excision, curettage, no colostomy. With these there were no deaths as a result of the operations, though Kelsey states that the mortality for excision is thirty-three per cent.

Let me, before presenting the history of a case, call your attention to the following significant facts: In a careful inquiry—made by Cripps—into the family history of a large number of cases of cancer, the percentage of mortality by that disease was found almost identical with that of the general population by the same. In a very large proportion the disease is so situated that an infection could have been plausibly possible. Infection of husband from wife suffering from cancer of cervix has been in several instances well authenticated by competent observers. A much greater frequency exists near the sea than inland, and both Sheurlen, of Munich, and Thoma, of Heidelberg, have demonstrated the frequent presence of micro-organisms (psorosperms), which, in their opinion have a specific relation to the causation of this disease.

In relative frequency of type, cylindrical-celled, flat-celled (epithelioma), and papillo-carcinoma stand in the order named. Allingham, who, in 1886, had already reported thirty-nine cases of excision, is authority for the statement that rectal carcinoma usually runs its course in twenty-four months. He notes, however, cases ending in death in from four months to four years. His experience had been also (contrary to that usually noted) that the disease occurs more frequently in males than in females, and that its most usual site is within three inches of the anus. Cachexia appears at a very early period. The ages of greatest frequency range from 45 to 55, though it has been noted as early as the age of 6. Cancer in this location frequently escapes the observation of the general practitioner, being mistaken for hemorrhoids; and, for this reason, too great care cannot be taken in the examination of middle-aged people in whom there are symptoms referable to the rectum.

Treatment.—James Adams urges that in every case there should be made a colostomy, saying: "In cases of any but the slightest degree the operation of removal may prove incomplete and the disease speedily return; . . . after complete extirpation of the lower end of the rectum the subsequent contraction is often very great, and even at times intractable, and in any case the healing of the wound will be much expedited and the chances of local recurrence diminished by diverting the course of the fecal matter."

Allingham justly condemns the making of a colostomy in every case of cancer of the rectum, stating that "often neither pain nor obstruction will ensue in months, or they may never occur and the patient may die from some other malady. Of course, if a surgeon at once persuades all his patients who have malignant growths in their rectum, to submit to colostomy under the promise that life will be prolonged or suffering averted, he will have many cases to report and very good but very valueless statistics."

There are four factors which make this operation justifiable: First, because the mortality of rectal excision can be immensely reduced by diverting the fecal matter from the site of the excision. Second, because there are in some of the cases excruciating pains, caused by the passage of fecal matter over the ulcerating carcinoma, which can be relieved by a colostomy, winning at the same time for the surgeon the gratitude of the patient. Third, because in those cases in which the disease extends higher than the lower three inches, there is sure to be sooner or latter a stenosis. This Jessop has demonstrated at the late meeting of the British Medical Association. He calls attention to the fact that where the disease is low down in the rectum complete obstruction seldom occurs, and that the opposite is true where the disease is high up. The reasons for this difference are to be found in the anatomy of the parts themselves; for while the rectum, as it approaches the outlet, becomes more closely applied to the sacrum and pelvic wall, in its superior portion it is comparatively free. Thus the contractile action of the colon is exerted with effect in forcing its contents through the contracted ring when that ring is fixed and immovable. But when the narrow portion is freely movable, as it is when situated in the upper portion of the rectum, the efforts of the bowel above succeed only in invaginating or otherwise displacing the growth, and fail altogether to effect any onward movement of the contents (Kelsey). Fourthly, it has been the experience of most operators that the cicatricial contraction which follows such an operation is often excessive and intractable, as in any of the inflammations, specific or simple, which so frequently result in a stenosis here. Allingham has found that if he would maintain the gut in a useful and patulous condition, it is necessary to have the patient

wear a guttapercha tube, which can be removed at will. Finally, an argument which needs no champion is the fact that thirty-three per cent. of all cases of carcinoma (as shown by the researches of Jessop in one hundred and two cases which were allowed to follow their course without any surgical interference) die from obstruction.

To sum up, I would urge that *prior to every excision in every painful case*, and in every case where the disease was situated *high up*, that a colostomy be made, the choice being in favor of the left inguinal. The method of excision recommended by the French surgeons has been that which I have utilized, preceding each excision, however, by a colostomy two or three weeks prior to the final operation. In this the main feature is a deep incision which exposes the posterior segment of the rectum from the anus to the coccyx, when it is an easy matter to dissect out the rectal tube until one comes to the anterior portion. Here, if it is found that the disease involves one or more of the coats of the vaginal wall it is, in my opinion, best to remove a longitudinal segment of the entire thickness of the same, as it both renders the operation safer and more easily accomplished, and does not, as Kelsey would infer, greatly increase the danger. When the sphincters are involved a circular incision should surround the anal opening, and all be removed together. Dr. Guerin's suggestion that the gut be cut through by the ecraseur, modified by the passing through the normal gut of several threads for purposes of fixation of the proximal end after removal, as recommended by Verneuil, has been the procedure employed in the excisions I have made. The proximal end is then to be stitched to the posterior angle of the perineal incision or to the left side of the coccyx, and, after stitching up the vaginal wound in much the same way as after a posterior colporrhaphy or laceration, deep transverse perineal stitches render the making of a new and extensive perineal body very easy.

When the type of the disease is that of the cauliflower-like growth known as papillo-carcinoma, I believe the best practice is to remove it with the curette rapidly and well down to the base of the growth. The hemorrhage, very active and easily provoked while in the soft tissues of the tumor, is easily controlled when the base has been reached. In two such cases I have been successful in for a time relieving them of their distressing symptoms, but have not been able to follow their history for more than six months after operation.

The case I now report is of interest in showing the benefit to be derived from surgical interference.

Case.—After having suffered with what she believed to be hemorrhage, the patient came to St. Luke's Hospital a year and a half ago, with symptoms of absolute stenosis of the intestine, and requiring immediate relief. The diagnosis of carcinomatous obstruction of the rectum being made, a colostomy in the left lumbar region was done, with relief to the urgent symptoms. After the lapse of three weeks, the artificial anus being well established and healed, an excision of the rectum was practiced after the usual methods by a deep posterior incision from the anus to the left side of the coccyx well down to the posterior wall of the rectum, which was then dissected laterally until the vaginal wall was reached, which was found to be involved to the level of the posterior lip of the cervix in the carcinomatous growth. The posterior wall of the vagina was removed, as well as the rectum, to this level, including the sphincter muscles. The rectum was stitched to the skin of the left side of the coccyx, and deep transverse stitches were inserted to make a new perineal body. There was a speedy union and rapid convalescence. After the lapse of one year she returned to me with the artificial anus presenting a normal rectal mucous membrane normally attached to the integument to the left side of the tip of the coccyx, with the artificial anus almost closed from surgical interference by Dr. John E. Owens, but with a return in the perirectal tissue of the original trouble to such an extent that the line of cicatrix in the vaginal wall posteriorly and in the anterior rectal wall was again invaded by the new growth, which was beginning to cause painful defecation as at first. The patient, being much frightened with the symptoms of a return, came to me requesting a repetition of the operation. This at first I refused to make, telling her that I did not believe her longevity could be increased by such a procedure nor her condition materially improved. She then consulted Drs. Parkes and Fenger, both of whom, she stated, promised to operate upon her and offered her hopes of at least temporary relief. Coming back to me with this history and the threat that if I would not operate somebody else would, I had her admitted, in the last week of September, 1890, to the Michael

Reese Hospital, where I excised the portion of the rectum which had been drawn down and attached to the integument, at a point on a level with the posterior lip of the cervix. I dissected out laterally, in so far as I could reach, all indurated tissue. I then found that it was impossible to bring the end of the rectum down to the integument, no matter how far I might extend my posterior incision, and decided that the best thing I could do would be to suture the end of the rectum at the top of the vaginal incision after the cicatrix had been removed. I did this, then united the vaginal mucous membrane, much as is done for a laceration or operation for posterior colporrhaphy, and brought the lateral pelvic tissues together by very deep, heavy silk sutures, and, strangely enough, obtained a perfect union. The patient has, since the second week in November, been at home, is feeling well, has gained in weight, and has several times come to my office, each time stating that she feels better than she did during the year which elapsed after the first operation; that she now has control of the bowel and is capable of evacuating its contents without any artificial assistance—that is, without a douche, which I advised when she first left the hospital.

I believe this to be a unique case. I do not find, in what literature I possess, reference to a similar operation. I have no doubt that she will ultimately have a return of the trouble, because the cicatricial contraction which normally occurs with any inflammatory deposit about the rectum, whether from specific or simple inflammations, has already produced some suspicious induration. (See *Society Reports* for discussion.)

AN INCARCERATED RETROFLEXED PREGNANT UTERUS, WITH GREAT DISTENTION OF BLADDER—SUCCESSFUL REPOSITION—RECOVERY. [1]

BY CORNELIA KAHN, M.D.
PHILADELPHIA.

This grave complication of pregnancy is comparatively rare, yet the importance of its early recognition and prompt treatment is so evident, that a report of every case of this nature must be of value to the profession. Gregoire, in France, Sir W. Hunter, in England, are said to have been the first to fully appreciate the existence of posterior displacements of the gravid uterus, and to have called attention to them. They are far more difficult to manage, and more serious in their consequences than those met with in the unimpregnated state, but of less frequent occurrence, or, at least, fewer come under the notice of practitioners.

This may be due to the fact that in the majority of cases, spontaneous cure occurs about the end of the third month, and the women have had no symptoms urgent enough to compel them to seek medical advice, or a miscarriage occurs, the cause of it not being traced to this condition. If this restoration does not take place of itself, or an endeavor made to rectify the abnormal position as soon as an augmentation of the pains and functional disturbances of bladder and rectum incident to first months of gestation, give evidence of the nature of the trouble, grave results may ensue. This retro-deviation may then end either in abortion, incomplete rectification or incarceration.

Jaggard says, that "The persistence of complete retroflexion and consequent incarceration must be regarded as exceptional events;" but the dangers to be apprehended, when they do occur are great. Cases have been recorded of proctitis, peritonitis, cystitis, sloughing of vesical mucous membrane, rupture of bladder, rupture of posterior vaginal wall, as well as of deaths from shock, exhaustion, uræmia, following these conditions. Other serious complications have also been noted. In the *Lancet* of December 31, 1887, page 1311, a case of retroversion followed by abortion and *sloughing* of vesical mucous membrane is reported. Elliott in "*Obstetric Clinic*" (1872) describes three cases at Bellevue Hospital with one death, and Barnes had four deaths from uræmia, and De Paul one death.

The sequelæ of urinary retention are of gravest prognostic moment, not only sloughing of a part or of the whole vesical mucous membrane, but necrosis of the bladder itself and its peritoneal covering has occurred. Haultain, in the Edinburgh Medical Journal, June, 1890, relates a case of exfoliation of the entire bladder wall, seven weeks after the reposition of an incarcerated gravid uterus. Abortion had been induced by the manipulations to replace the organ and incurable incontinence was the result of the death of the vesical tissue (replaced by connective tissue growth). The following are the notes of the case which forms the basis of the present paper.

C. B., aged 34, German, married, presented herself on Sept. 8, 1889, at the dis-

[1] Read before the Alumnæ Medical Society of Philadelphia.

pensary clinic of the Woman's Hospital in great distress, complaining of intense pain in the abdomen and that she could not "pass her water." With great difficulty, she was placed upon the table for examination. To lie down seemed almost impossible, so severe was the suffering occasioned by the effort to remain in that position. On exposing the abdomen, we saw immediately that there was a peculiar tumor to diagnose. The distension was most marked, the integument having a bluish thinned-out appearance, suggesting the presence of a rupture. The swelling was not uniform, although it extended to the umbilicus; for in this region, there was a pointing or bulging which simulated a hernia.

Palpation and percussion were too painful for us to elicit any physical signs, and a vaginal examination (exploration) was made to ascertain the condition of the pelvic organs. The cervix was found drawn up near the symphysis pubis and a round body was felt in the posterior *cul de sac*. The os uteri having the softened velvety character of early pregnancy, we questioned the woman and found that the menses had last appeared in June.

An attempt was made to empty the bladder with a metallic catheter, preparatory to more thorough examination, but failing to draw any urine, although the meatus urinarius was accessible, we called upon Dr. Fullerton to assist us. She suggested our using the flexible English catheter, and as this instrument did its work, we witnessed the peculiar tumor progressively diminish and disappear. The patient's face, relieved of its suffering and strained look, gave evidence that the pain had ceased.

This was a striking example of the importance of the use of the long flexible catheter in diagnosis of vesical complications in women. Failure to draw urine with the metallic catheter often misleads the physician as to the real condition present, and serious results have been reported.

Three pints of urine were drawn off, but the bladder was purposely not completely emptied. The urine was found to be of a sp. gr. of 1015, neutral reaction, and without albumen.

Bi-manual examination now confirmed the supposition that there was a retroflexed, incarcerated pregnant uterus. Freed from her urgent symptoms the patient was allowed to go home with directions to assume the knee-chest posture often during the day, and to try to urinate while in this position, or bending forward, and return to the dispensary in a few days. On the 11th, three days afterwards, she presented herself again with no marked improvement in her condition, the bladder being again distended, although not quite to the same size as before.

Catheterization again relieved the pressure symptoms, but the patient was advised to come to the hospital for treatment that could be directed towards correcting the displacement. On the next day, she was admitted, and the following history elicited:

Patient had a good family history and had a healthy childhood. Began to menstruate when fifteen years old, and although not painful the flow was always irregular. Constipation was a persistent habit with her. She was married twelve years before, in her twenty-third year,—had five children, the youngest being two-and-a-half years, and no miscarriages. When, after her first confinement, menstruation was again established, it was painful, although it had not been so previously. She stated that "bearing down pains with falling of the womb" and some trouble with urination had occurred following the puerperal periods, with the last two children.

Both these latter symptoms, however, disappeared gradually without treatment, the patient having an interval of comparative comfort. Conception again took place. As already stated, she ceased to menstruate in June, and began then to experience anew the "bearing down pains," the sense of weight and fullness in pelvis. She continued doing her usual work, including the lifting of heavy washtubs, etc. In the second month, micturition became more frequent, effected with difficulty and accompanied by pains in the back and down the legs. She was still of a very constipated habit, although there does not seem to have been marked distress with defecation. Vesical tenesmus gradually increased, micturition was very difficult, and when she came to us the pain had grown intense, and the flow of urine very scant. Every morning there was swelling at the hypogastrium and inability to urinate until after moving about for a couple of hours. Both walking and sitting were alike painful, and the nervous system was necessarily affected to a marked degree.

At last voluntary micturition became impossible. Dysuria gave way to the "incontinence of retention," and from Saturday evening to Monday morning, when the patient came to the dispensary, scarcely any urine was passed, coming merely "drop by drop." Her suffering was extreme, the in-

effectual straining was intolerable, and she was forced to seek relief. Her visits to the clinic and the treatment received have been already detailed. Having now entered the Hospital 5 days after first coming under observation she was put to bed in the knee-chest position, in which she lay for an hour, only to resume it again after resting awhile on her side. After emptying the bladdər, Dr. Fullerton, with careful manipulations (two fingers in the vagina, making gentle pressure upon the retroflexed fundus through the posterior *cul de sac*), succeeded, to some extent, in disengaging the body of the uterus from its imprisonment under the promontory of the sacrum, and the patient gave expression to a sense of relief and comfort after this procedure. The vagina was now packed posteriorly with wool pledgets, and a No. 8 flexible catheter inserted in the bladder and retained until the next day, so as to prevent a full bladder from interfering with the correction of the uterine displacement. The necessary adjunct to this line of treatment—the knee-chest position was not forgotten, and the patient was ordered to lie thus as constantly as possible—pillows being placed under her to give her the necessary support. On the following day, the uterus was found in a much better position, the fundus having risen into the abdominal cavity. The pledgets and catheter were now removed and an Albert Smith soft rubber pessary inserted—the patient still remaining in bed. She was now able to urinate without pain. Two days later, the fundus uteri was anterior, the cervix posterior. Patient was now in good condition, gestation not seemingly affected by either the displacement of the organ or by the efforts at restoration to its normal position. The patient was discharged from the Hospital with instructions to assume at times the knee-chest position, to avoid constipation, to empty bladder regularly, and to return when six months pregnant to have the pessary removed, if there should be no occasion, in the interval, to present herself earlier.

From this time forward, she experienced no further trouble, and succeeded in securing a daily movement of the bowels, thus avoiding one factor in the causation of uterine displacements. In due time she was delivered, in the Woman's Hospital, of a fine child, after a normal, easy labor. The recovery, in this case, is thus shown to have been a prompt and permanent one, the danger that threatened was averted, and the lives of both mother and child preserved.

In reviewing the history of this case, there are some points I would comment upon. Authorities differ as to the occurrence of posterior displacements during pregnancy and also as to their abrupt or gradual origin. Barnes says that retroflection, pure and simple, does not take place in an impregnated uterus, but that it supervenes on some degree of retroversion or prolapse. According to Tyler Smith, "retroflection of the gravid uterus presupposes retroflexion of unimpregnated organ."

Meadows "does not see any causative relation between misplacement of the non-pregnant and pregnant state." Jaggard admits the possibility of *acute* retroversion in a prolapsed pregnant uterus. Many others might be quoted to show the differences of opinion. It is also an open question whether the distended bladder acts as a cause or is a result of the retro-deviation. Sir W. Hunter's opinion "that retention of urine was the primary cause seems to be modified now by the belief that it is an important adjunct in its production, and an obstacle to its reduction, rather than the initial cause.

In the case I have reported, the history of recurrent attacks of bearing down efforts and difficult micturition, with obstinate constipation and painful menstruation since birth of first child, would seem to favor the view of some form of displacement having existed at times during these years.

The early appearance of severe symptoms after this last conception would seem to confirm this, and such being the case, it is easy to conceive how the continual straining at stool, vesical tenesmus and pressure of abdominal muscles in the heavy lifting, would act to depress the fundus still more and thus establish a retroflexion. The restitution of the organ was opposed also by the distension of the bladder, which acted not only by pressure, but by its dragging up the anterior wall of cervix in its ascent into the abdomen. The uterus, thus crippled in its natural movements to free itself from its imprisonment, remained impacted in the hollow of the sacrum.

Diagnosis of these retro-deviations says Parvin, should not he difficult if a thorough examination be instituted, but errors have been made. W. S. Stewart lately reported a case that was diagnosed as a fibroid going to term with the retroflexion unreduced, and in danger of serious exhaustion at time of labor.

In treating this condition of incarceration much difficulty has been experienced in many cases in introducing the catheter. This woman was fortunate in that the meatus urinarius was not so inaccessible.

Various instrumental methods have been employed to rectify the malposition; but gentle vaginal and rectal taxis in the knee-chest posture, is thought to cause less trauma, and must be tried first. It often has been necessary to administer chloroform before reduction was possible. Dr. Playfair, in two cases, effected a cure in twenty-four hours with continuous elastic pressure by means of a pyriform India rubber bag distended with water or air placed in the vagina. Barnes says, frequent daily catheterization cures in a week. Authorities also differ in their modes of after treatment. Bandelocque resorts to the use of the pessary. Cazeaux advises the horizontal position up to sixth month of pregnancy. Jaggard recommends rest in bed in the lateroprone position until the uterus is of sufficient size to retain its position in the abdominal cavity.

With our patient, the line of treatment was simple and rational. The first measure to be resorted to before attempting reposition of the displaced organ, the evacuation of the bladder, was promptly done, and its refilling prevented by the constant drainage through the retained catheter. The knee-chest position and packing of the vagina, after the manipulations, and ridding the rectum of all fœcal accumulations, were the elements of successful treatment, which lasted only three days. The use of the pessary, adjusted before patient left the bed, with due attention to the functions of bladder and intestines, and the frequent employment of the genu-pectoral posture, assisted in maintaining the pregnant uterus in the normal relation to the line of the pelvis. Rest in bed for any length of time was not practical, as there was a family of children to be cared for.

The capacity of the distended bladder, in the case reported, was about fifty ounces, but in one of those related by Elliott the bladder contained the remarkable quantity of one hundred and forty ounces. Notwithstanding this fact, the patient did not suffer as had ours, having no symptoms urgent enough, even to direct the attention of the physician to this viscus. In the case, already cited, of Haultain's the bladder held as much as one hundred ounces of porter-colored, offensive urine, even though its walls were in a state of decomposition and consequent diminished muscular elasticity.

Dr. E. Richter has found that fresh urine destroys the bacilli of anthrax, cholera and typhus.

Society Reports.

The Gynecological Society of Chicago.

Dr. L. L. McArthur read a paper on (see p. 532).

Cancer of the Rectum.

Dr. C. T. Parkes.—The case as presented by Dr. McArthur is very interesting to me, and, I think, he is to be complimented on the skillful attention he has given to this patient and the success which has resulted from his interference. It seems to me, we must look upon this operation for the relief of this terrible disease mainly as a palliative treatment; it is seldom curative. Certainly it removes the manifestations of the disease for a time, and, above all, is desirable, as Dr. McArthur has said, from the fact that it relieves the patient from the local distress caused by the disease, especially from pain, which is present in all these cases, and the symptoms of on-coming obstruction which accompany the later stages. My experience with it has been rather moderate; as I recall the cases I have met, and have thought a little about them since receiving the notice of this meeting, there come to mind *nine* cases in which operation has been done for excision of the rectum, two cases in which simple incision was done, and two cases which are interesting from the fact that they accompanied the presence of ovarian tumors, and one case which was situated very high in the rectum and no interference was practiced—in all fourteen. Of the nine cases in which excision was done, five were operated upon according to the plan of Kraske; in the others success was attained in the removal of the manifestations of the disease by merely external incision of the soft parts, without interference with the sacrum or coccyx.

Of these cases, which represent a period of work of eight or ten years, some are living to-day, but most of them are dead. None of the cases of excision were preceded by an opening into the colon. I think the statistics which the doctor gives as to the mortality of the disease as the result of immediate excision is based upon the results of pre-antiseptic days rather than the present. I am not one of those who believe that the contact of fecal matter with the wound is at all times hurtful, as I have had in my experience many cases in which wounds have been bathed in fecal matter without any septic condition following.

I can see readily enough that the previous operation for an artificial anus can be a benefit to these cases, and will likely predispose to the earlier and more rapid healing of the rectal wound, simply because it prevents the fecal material from passing over the raw surface. The operation of forming an artificial anus in itself is of little consequence, and should be, as a rule, attended with little fatality. That it is a necessary procedure I am not inclined to believe; neither do I think that it makes very much difference in the mortality. As far as the relief given in preventing the discharge from coming over the wound is concerned, I have to agree with Dr. McArthur's statements.

The disposition is in all these cases to a comparatively rapid return of the disease. We must always remember, in the treatment of cancer here as well as elsewhere, that the operation itself may stimulate or produce infection. In two cases in which the operation was done by myself, there followed no local manifestations of return of the disease, but within eighteen months there appeared to be general infection of the entire body, as shown by evidence of disease in the liver and in the lung, and the presence of cancerous nodules of different sizes in the integument.

There is no question but that every one of these patients will be grateful to the surgeon for the removal of the manifestations of this disease; but, as I said before, we must look at it in the true light and tell these patients that the relief is only temporary and cannot often be curative where the disease is really cancerous in its nature. Again, we must bear in mind that quite a number of surgeons of great experience—men who have seen this disease in all its conditions and ravages—believe that the establishment of an artificial anus itself is a sufficient relief to the case. Dr. Thomas Bryant, of London, is not an advocate of excision, but is an advocate of an artificial anus and relieving the patient entirely of the necessity of using the diseased portion of the bowel for the transmission of fecal matter, and thereby allaying inflammation.

Again, we must remember that other operations are done besides excision of the rectum, which is a formidable operation and leaves disgusting results in many cases. Some other operations have been done which surgeons of experience believe to be efficacious; these are local in character—that is, the complete division of the mass backward towards the sacrum, in that way providing for the easy exit of the fecal matter. Of course, the era of operative procedure is upon us, and particularly is this operation advocated by European surgeons, and also very largely by American surgeons; but I think if all the cases were examined as carefully as those cases have been which Dr. McArthur has presented to us to-night, and discussed as coolly and calmly as he has discussed them, none of us would be very much in favor of promising a great deal for the operation.

Dr. Henry T. Byford.—I would like to emphasize what Dr. Parkes has said, that this is a palliative operation and not justifiable when it is immediately very dangerous to the life of the patient. The case related was very interesting to me, because it is similar to a case which I have treated, and which illustrates the principle which should be carried out in treating cancer of the rectum in women. In this case the sphincter was not involved, although the rectum from about two-and-a-half above down nearly to the sphincter was affected on its anterior and lateral aspect. I removed portions of the lateral and anterior rectal walls, and the posterior vaginal wall. Instead of drawing the parts together in front of the rectum, I operated upon the principle that all raw tissue not covered by mucous membrane will contract and obliterate the entire tract within it; so I endeavored to secure as large a surface of mucous membrane for the canal as possible by leaving the vagina open and merely closing up the vaginal entrance. There is another reason for removing, in cancer of the rectum, all of the rectum that we can, viz., that a return of the disease in connective tissue is not as painful as when it attacks the viscera. In this case the patient was able to evacuate the bowels until the entire pelvis was filled up with a mass of carcinomatous tissue, without very much pain. She died finally of exhaustion more than anything else. The point in all these cases is to get as much mucous membrane as possible, using the vagina the same as in any other operation.

Dr. L. L. McArthur, in closing the discussion, said: In presenting the patient this evening, I did not do so to advocate such an operation, although it does seem to me that, in cases in the female in which carcinoma occurs low down in the rectum, in reality it would be a procedure more advisable than to make an artificial anus at one side of the tip of the coccyx, because of the statement of the patient that she knew when the bowels desired to move. She had a peculiar feeling, she says, and has the power to expel the contents, thus escaping

the exceedingly distressing symptoms of involuntary discharges, which always occur with an artificial anus at other points. In regard to the statistics which I quoted as collected by Kelsey, in the article which he wrote on this subject for the "Reference Hand-book of Medical Sciences," published in 1886, he stated that the mortality from the operation of excision was thirty-three per cent. In Sajous' *Annual* for 1890, there is a collection of statistics after Kraske's operation, and the mortality is stated at fifty per cent. Kelsey happens also to be a contributor to this department of Sajous' *Annual,* so the mortality has rather increased than decreased for the last year, according to the same man's statistics. He bases this fifty per cent. mortality on seven cases done by Kraske himself, three by Schönborn, one by Rinne, and the remainder by Lauenstein, twelve in all, in which six died as the result of the operation; some by septic peritonitis (two), some by sepsis (two), and some from exhaustion.

As Dr. Parkes says, there are a large number of surgeons who advocate simply making a colostomy and interfering to no further extent with the case. In some excellent statistics collected by Cripps, we find that out of cases which he watched personally in London hospitals and studied carefully, life was lengthened on the average from seventeen months to twenty-two months—that is, there were five and a half months added to the longevity by simply making a colostomy; which shows that it is decidedly advantageous. Colostomy, I believe, will aid in lowering the mortality in cases of excision, whether done for pain or for obstruction. As to the operation being of dubious value, there is much to be said on both sides; there are, however, some well-recorded cases in which, the operation having been performed at an early day, the life of the patient has been preserved. One case was living in 1886 that had been living for seven years since the operation, and no return was to be seen, and five cases in which no return was seen in two years.

It has impressed me that some of the gynæcologists of the Society would comment upon the probability of endometritis with infection through the uterine canal and tubes as being very likely to occur in such a procedure, as was exhibited in my patient, and I would like to ask the President whether such an inflammation would be probable in a woman who had passed the menopause.

EDISON'S EXPLANATION OF THE AMPERE AND THE VOLT.

During a recent examination a lawyer put the following question to Thomas A. Edison:

"Explain what is meant by the number of volts in an electric current?" To which he replied:

"I will have to use the analogy of a waterfall to explain. Say we have a current of water and a turbine wheel. If I have a turbine wheel and allow a thousand gallons per second to fall from a height of one foot on the turbine, I get a certain power, we will say one horse power. Now the one foot of fall will represent one volt of pressure in electricity, and the thousand gallons will represent the ampere or the amount of current. We will call that one ampere. Thus we have a thousand gallons of water or one ampere falling one foot or one volt or under one volt of pressure, and the water working the turbine gives one horse power. If, now, we go a thousand feet high and take one gallon of water and let it fall on the turbine wheel, we will get the same power as we had before, namely, one horse power. We have got a thousand times less current or less water, and we will have a thousandth of an ampere in place of one ampere, and will have a thousand volts in place of one volt, and we will have a fall of water a thousand feet as against one foot. Now the fall of water, or the height from which it falls, is the pressure or volts in electricity, and the amount of water is the amperes. It will be seen that a thousand gallons a minute falling on a man from a heighth of only one foot would be no danger to the man, and that if we took one gallon and took it up a thousand feet and let is fall down it would crush him. So it is not the quantity or current of water that does the damage, but it is the velocity or the pressure that produces the effect."

It has been calculated that the electromotive force of a bolt of lightning is about 3,500,000 volts, the current about 14,000,000 amperes, and the time to be about $\frac{1}{20000}$ part of a second. In such a bolt there is an energy of 2,450,000,000 watts, or 3,284,182 h. p.—*Scientific American.*

Gunpowder Stains of the Face may be removed by painting with biniodide of ammonium, distilled water, equal parts; then with dilute hydrochloric acid, to reach the tissues more deeply affected.—*Revue de Therapeutique.*

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few para graphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

Notice to Subscribers and Advertisers.

All bills owing the MEDICAL AND SURGICAL REPORTER, on May 1st, and after, must be paid to the present Editor and Manager.

THE PRESENT STATUS OF THE KOCH TREATMENT OF TUBERCULOSIS.

The absence of exact science in the medical knowledge of the day, has perhaps been nowhere so well exemplified as in the extreme readiness of both profession and laity to accept the unproved word of a single man in relation to a hitherto unanswered and weighty question in therapeusis—that of the existence of a specific control of the tubercular process. Nor is the precipitate haste on the part of the clinicians to condemn the method, as yet not even half tried, any more evidence of the development of stable principles in our methods of combatting disease processes. From a theoretical stand-point, excluding from present consideration the general care and management of the patient, the destruction, or modification of the materies morbi is to be accomplished in four probable ways, these include: the utilization of the antagonism of micro-organisms toward each other; the deleterious effect of micro-organismal products on the growth of micro-organisms; the unfavorable effects on micro-organisms of certain agents of mineral or organic origin; and the production of general surroundings unfavorable to the advance of the infection, both in the individual and in the community. To the second of these groups is to be referred the method recently proposed by Prof. Koch for combatting the tubercular process. This method, which is substantially if not precisely identical with the measures previously employed and announced by Dixon of this city, has for its underlying principle a fact, the verity of which may easily be recognized by analogy in numerous instances of the incompatibility of waste products with productive growths. Thus alcohol, as a product of vegetable activity manifested as fermentation, when present in proportions beyond 20 per cent., is sufficient to retard and eventually destroy the actions and vitality of the ferment. Nor is the use of the products of bacteria as a means of altering the further growth of bacteria in the animal tissues by any means a recent one, as may be noted in relation to the work done upon the bacillus pyocyaneus by Charrin and others. Separation of the fluid product of the growth of this last bacterium from the culture itself, by means of an unglazed porcelain filter, and inoculation with this sterile product has prevented the inception of pyocyanic disease in animals after subsequent inoculations with virulent matter. Probably the same principle underlies the Pasteur method of hydrophobic prevention; and

the field of preventive medicine glows with promise of great and near discoveries in this same line in other diseases.

The substance used by Koch in his experiments and more recently in the treatment of tuberculosis in man, and which, as already stated, is produced in practically the same manner by Dixon, is obtained from cultures of tubercle bacilli exposed to altered conditions of life by means of extraction with some such menstruum as glycerine. This material, from which no definite active agent has been eliminated by Koch, when brought into contact with tubercular growth in the animal economy, is announced to produce decided lowering of activity of growth and eventually, if in sufficient proportion, to permanently stop the morbid process. In the animal economy, further, as an evidence of its action, whether by direct action upon the germ, or by inducing deleterious changes in the tubercular tissues, there is manifested a febrile re-action; and as a result of its action it is stated that there is a destruction of the diseased structures and subsequently their replacement by cicatricial tissue. The exact mode of operation is not known, various theories having been offered in explanation.

Such was the knowledge established by the researches of Dixon and Koch, and eagerly seized upon by the entire world in the expectation of mastering tuberculosis. In the natural course of the rapid popularization of so important a discovery, the limits of its application have been wittingly as well as ignorantly widely overstepped; badly diagnosed cases and cases whose only cure can be death have been subjected to the vicissitudes of the treatment. With an eye singly to the result of the means upon the tuberculosis, cases have been permitted to approach the fatal termination because of the neglect of the true end, the recovery of the patient; and too often even the increased nutritive need of the weakened system has been passed by in the endeavor to overcome the process at fault. Clearly, in the method of action of the substance it was to be recognized that its only safe application could be found in the most localized forms, and preferably in foci where elimination of the products could be performed most thoroughly and with least severity to the organism; nevertheless, in the mad hurry, cases of advanced degrees of the disease and cases marked by generalization of the malady have been permitted the treatment, only to swell the death list which has been heaping discredit upon the measure. Where tubercular foci are numerous and widely distributed, if each focus is to be the scene of rapid necrotic processes, each followed by a local focus of reactive inflammation, what is to be expected but the effects of an intense toxæmia and fever, which are the necessary attendants of such a condition?

Where the lungs are riddled with the tubercular changes of late chronic phthisis, what is to be expected if this new therapeutic agent accomplish the best possible results, and yet leave a great mass of cicatricial tissue to block up and hamper the pulmonary tissue? Moreover, what of that great mass of patients, from whom, the treatment having failed to produce notable external changes, the lymph was withdrawn and death followed—are there positive evidences of no palpable changes in the internal tubercular localities in the line of change indicated? How is it possible from post-mortem appearances to affirm absolutely the generalization of the tubercular process in this or that position, within a definite and brief period? These are the considerations upon which more information and more definite knowledge should be demanded from those who condemn the method. Its action upon true cases of lupus has been too decisive to permit, in other localized forms of tuberculosis, any discredit until more exact information is had. The conflict of reports is too great at the present date and the tendency of medical opinion too observant of so-called policy to allow an absolute decision; this will and can only come when the lymph method has fallen entirely out of injudicious hands and is left to the investigation of the cautious and thoroughly interested.

There are other phases of the subject, too, which cannot fail to attract attention in the future. How much of the severity of the reactions, and how much the failure in results may be due to the presence of substances other than the essential toxalbumen in the lymph? What auxiliary measures are those best adapted to the furtherance of the favorable results of treatment? Finally, if even in mild cases of pulmonary tuberculosis failure should be established, there is one other point of the utmost importance to be further examined. In the earliest paper of Dixon (Med. News, Nov., '89), antedating Koch's announcement by more than a year, there were distinct expressions of the development of immunity in animal tissues against the tubercular process by this general method; and investigations carried on in rabbits and guinea pigs have with considerable uniformity confirmed this hypothesis. It is undoubtedly an injudicious act to inoculate healthy individuals with an agent of which so little is known as this mixture of the retrograde products of tubercle bacilli, but it has been and doubtless will be done more or less frequently for a time. There are no positive arguments in relation to tuberculosis refuting the usual rule of infections to protect against themselves; and there do occur occasional cases whose clinical histories present features not averse to this view. For example, within the knowledge of the writer, a young man of questionable family history, who for 20 years had had a destructive scrofuloderm only cured within the past few years, became accidentally inoculated with tuberculosis, while performing an autopsy upon a tubercular body. To ordinary observation, the usual course of inoculated tuberculosis was manifested, the healing of the original wound, the period of some days' quiescence, the formation of a nodule at the site of sore, and the breaking down of the surface into a slightly purulent fluid to the formation of a tubercular ulcer. Within more than a month no lymphatic involvement had become manifest, and the local node was removed by operation. Thus far, nearly five months, there is no evidence of general infection. Such cases have occurred before and the process remained for a long time localized—yet may not the previous tubercular condition as manifested by the existence of scrofula, have exerted some limiting influence upon the inoculated process? The existence in otherwise normal lungs of isolated and calcified nodes of old tubercular processes may suggest the protective value of the results of the prior disease; and where these are associated with evidences of general advancement of the process there enters the question of whether there had not been at least a temporary protection analogous to that afforded by vaccination.

This then is the status of the proposition. The statements denying value to the treatment of tuberculosis by the method of Koch, whose claim to consideration rests upon what appear to be general laws, and is corroborated by laboratory researches, lose their own force from the numerous faults of omission and commission met in the widespread and ignorant application of the method. Even should it fail as a curative, except in the localized and superficial variety known as lupus, there is yet another field for its usefulness open to investigation, its possible preventive power.

Dr. J. T. Rothrock, Prof. of Botany, in the University of Pennsylvania, has sent out his vacation circular for the fourth season.

The Doctor's plan is to take charge of lads who are below par physically, but who need moderate, systematic exercise in the open air, good food, and early hours, rather than medicine. The plan includes sailing on one of the safest of vessels, deep-sea fishing, football, lawn-tennis, target practice, etc. At night instruction is given on methods of prompt action in an emergency—"until the doctor comes."

Thus far the Professor asserts there have been nothing but good results from this novel plan.

Dr. Rothrock is a gentleman of experience, a physician, explorer and teacher. Parents may trust their sons in his hands with

the assurance that they will be conscientiously and wisely cared for.

OBITUARY.

DR. JOSEPH LEIDY.

On April 30th, after a brief illness, passed away, Dr. Joseph Leidy, Professor of Anatomy and Zoology in the University of Pennsylvania,——the most distinguished naturalist of America, a man whose lasting achievements secured the highest recognition throughout the entire scientific world, whose personal characteristics won the warmest affection of all who had the privilege of his friendship.

Joseph Leidy was born in Philadelphia, Sept. 9th, 1823. His inclination towards the study of natural history was early manifested, when, as a school boy, he secured text-books and began the study of mineralogy and botany, thereby laying the foundation of that immense store of knowledge, which his unaided efforts and ceaseless industry made his own. As a youth, he also displayed a remarkable facility for drawing, a talent which, in after years, rendered his scientific contributions conspicuous.

After several experiences, it was determined that he should adopt a profession, in which his devotion to the natural sciences—becoming ever more pronounced—would find opportunities for congenial employment; he, therefore, in 1840, entered upon the study of medicine, under the guidance of Drs. James McClintock and Paul B. Goddard, graduating from the Medical Department of the University of Pennsylvania in 1844. His thesis was an admirable essay on the "Comparative Anatomy of the Eye of Vertebrated Animals."

During the years of his medical course, his favorite studies in the domain of more purely scientific biology were by no means neglected, for in the same year of his graduation, he contributed a brilliant chapter on the "Special Anatomy of the Terrestrial Molusks of the United States" to Binney's monograph.

Immediately after receiving his degree, he became assistant to Prof. Hare, the distinguished occupant of the chair of Chemistry in the University of Pennsylvania at that time, thus already indicating the broadness of his scientific interests. In 1845, Dr. Leidy was appointed Prosector in Anatomy, thus beginning the services in the anatomical department of the University, which, with a slight interruption during the succeeding year when he was demonstrator in the Franklin Medical College, have terminated only with his death. As Horner's successor, Dr. Leidy became, in May, 1853, professor of Anatomy in the University of Pennsylvania, to which chair that of Zoology and Comparative Anatomy was added a few years ago. In 1871, he became, likewise, professor of Natural History in Swarthmore College.

Three years after his graduation, "The Fossil Horse of America" appeared, the first of those paleontological contributions which were to make Leidy's name known in all lands. The most important of these have been:

Ancient Fauna of Nebraska. 1853.

Memoir on the Extinct Sloth Tribe of North America. 1855.

Cretaceous Reptiles of the United States. 1865.

Extinct Mammalian Fauna of Dakota and Nebraska: together with a Synopsis of the Mammalian Remains of North America. 1869.

Contributions to the Extinct Vertebrate Fauna of the Western Territories. 1873.

Description of Vertebrate Remains from the Phosphate Beds of South Carolina. 1877.

The preparations of these monumental works, however, by no means exhausted the industry of this indefatigable worker, for his additional contributions during these same years were numerous and varied.

Among the first in this country to use the microscope as an instrument of scientific research, Prof. Leidy always delighted in studying the minute forms of life and the details of structure it alone revealed. Early

in his career, his classic paper on "Researches on the Comparative Structure of the Liver," (1848) and other kindred contributions established his ability as an histologist.

The study of parasites also became a favorite field with this investigator, whose numerous discoveries, as recorded in the Proceedings of the Academy of Natural Sciences of Philadelphia, bear testimony to the success with which his labors were attended. It is interesting to note that, in 1846, Dr. Leidy recorded the discovery of a species of trichina in the hog, and stated that it appeared to be identical with the trichina spiralis, which he had met with in the tissues of the human subject; later, this observation materially aided Leuckart in unravelling the relation between the parasite in man and in the hog. The appearance, in 1853, of the beautifully illustrated monograph, "Flora and Fauna within Living Animals," added a contribution of permanent value to the literature pertaining to microscopic parasites, to which its author subsequently made so many important additions.

The fondness for the study of the lowest forms of life, which had always been a source of never failing pleasure and recreation from the fatigues of more burdensome duties, led Dr. Leidy to undertake a systematic investigation of the forms found in this country. The results of this research appeared in the quarto volume, "The Fresh-water Rhizopods of North America", the splendid illustrations of which are the delight of every student. These plates, charming as they are, in many instances fall far short in reproducing the exquisite beauty of the original drawings from Leidy's skillful pencil and brush.

As teacher of anatomy in a great medical school—in which capacity not a few readers of the REPORTER have profited by his learning, during the thirty-eight years that have elapsed since his accession to the chair—Dr. Leidy appreciated the burden imposed on the student by the useless complexity of nomenclature, as well as by the perpetuation of errors grown classic by the sanction of precedent. He, therefore, set about the preparation of a text-book which should describe the human body as he saw it, freed, as far as possible, from all cumbersome terms; in 1861 was published "An Elementary Text-book on Human Anatomy," which for clearness and accuracy of description has never been surpassed; the second edition of the book (1890) even more fully justifies its favorable reception.

Some idea of the achievements of this life of ceaseless industry and untiring devotion to investigation may be had, when it is learned that the published communications, of all kinds, number about one thousand. While Prof. Leidy's eminence as a great naturalist has been cheerfully accorded at home, foreign countries have not been tardy in expressing their appreciation of the valuable services he has rendered in the advancement of those fields in which he has labored, since the honors conferred upon him by learned bodies abroad, include honorary membership in almost all the foreign societies of note devoted to the natural sciences.

The peer of the greatest, Leidy, together with such men as Owen and Huxley, Johann Müller and Agassiz, Koelliker and Henle, represented a generation of scientists almost past away—men, whose privilege it was to be of the van-guard of Biology, to live in those golden days when, on every side, new discoveries rewarded the scrutiny of the keen investigators, whose minds, already richly stored by broad training, became the repository of an ever-widening insight into natural phenomena. Men, whose energies were engaged in mapping out the salient landmarks of their science, whose comprehensive field was all nature, and on whom the limitations of an age of specialties had not been exerted.

Great as our admiration and respect for the splendid scientific attainments of Dr. Leidy must always be, it was, however, the personality of the man that drew towards him the warmest regard of all who came within his influence. Who that learned to know him—majestic in his noble simplicity,

unassuming in his greatness, approachable by all seeking knowledge, to whom the youngest student turned assured of a kindly reception, a patient ear, and sound advice; ever the last to allude to his own achievements, but fearlessly expressing his own honest beliefs when occasion demanded, devoting to science his entire life, not for his personal glory, but for the advancement of knowledge—could not fail to honor the man truly great and good! A nature to which petty jealousy and conventional circumlocution were alike unknown. A man whose tender heart and quick sympathies were overruled alone by his sense of duty, and by his absolute, unwavering devotion to the truth. G. A. P.

CORRESPONDENCE.

Dr. S. E. Young of Midland, Ga., writes:

Please inform me, (1.) Whether females experience an orgasm in sexual intercourse, similar to that experienced by males.

(2.) Give the philosophy of such orgasm.

(3.) You will also oblige me by stating whether women who are pregnant have any sexual propensities.

(4.) Advise me as to the probable procreative powers of a man who has twice had double gonorrhœal epididymitis, each epididymis being left somewhat nodular.

(5.) How can seminal fluid find its way into the receptaculum seminalis when the calibre of each vas deferens has been obliterated by adhesive inflammation?

[(1.) As far as our information goes the orgasms in the two sexes are essentially identical.

(2.) Not knowing the philosophy of the operations in the nerve cells we cannot explain.

(3.) Yes, as a rule, but in abeyance.

(4.) Practically *nil.*

(5.) Of course, if the vasa deferens are obliterated, the seminal fluid could not find its way into the receptaculum save by burrowing through the tissues, which is highly improbable.—Ed.]

PERISCOPE.

THERAPEUTICS.

THE USES OF NITRATE OF SILVER AND SULPHATE OF COPPER IN OPHTHALMOLOGY.

Grandclement (*Lyon Médical*, March 8, 1891) carefully reviews the principal remedies used locally in eye affections, with especial reference to the sulphate of copper and the nitrate of silver.

He considers the copper salt one of the best agents in the treatment of granular ophthalmias, applied either in solution or in the solid form. The cauterizations are painful even after the previous use of cocaine. It, however, is one of the most serviceable remedies in all the superficial inflammations of the eye. The *divine* or blue stone is said to be composed of equal parts of copper, alum, and nitrate of potassium.

The nitrate of silver is extremely dangerous in ulcerations of the cornea, as it is very apt to form, in such cases, disagreeable incrustations of chloride and albuminate of silver. In the treatment of purulent ophthalmia the author has been in the habit of cauterizing the conjunctiva every twelve hours, neutralizing the strong action of the salt with a little salt-water applied by means of a soft brush. Endeavors should always be made to protect the cornea from the action of the silver nitrate. The solution of this salt should be freshly made and placed in a black bottle, otherwise it will decompose into the oxide of silver and nitric acid, this producing deep eschars upon the conjunction. In spite of these incoveniences, however, nitrate of silver is the best germicide, so far, in the treatment of purulent ophthalmia. The author has obtained rapid and beneficial results in the treatment of crescentic and sloughing ulcers of the cornea by means of a finely pointed stick of nitrate of silver, being careful not to touch the borders of the ulcers.

THE INFLUENCE OF WARM ENEMATA IN THE TREATMENT OF TYPHUS FEVER.

From a study of the subject, T. K. Geisler (*Æsterr ungar Centrablatt*, Feb'y, 1891), draws the following interesting conclusions: 1. Immediately after the injection the temperature of the whole body is somewhat raised (maximum 0. 2.° C). 2. Warm enemata exercise a favorable influence upon the intestines, as they diminish the number and

quantity of excreted matters retained in them. 3. The injections provoke a rapid fall of temperature and transform a continued fever into a remittent and intermittent disorder. 4. After the administration of the warm enemata, the pulse immediately becomes diminished in frequency, but it returns to its original rate in about an hour. The pulse in general is very hard and full and the cardiac contraction very strong; the dicrotism is little influenced. 5. The respiration, soon after the injections, is generally hurried. An hour afterwards, it begins to get slower. 6. The blood pressure is increased by warm enemata. 7. Under the injections the quantity of urine is increased, and its specific gravity diminished. 8. The cutaneous and pulmonary exudations are diminished.

UNTOWARD EFFECTS OF EXALGINE.

A case of poisoning by exalgine is reported by Buisson (*Bull. Génér. de Therap.*, March 15, 1891). A man, 60 years of age, suffering from influenza, accompanied with gastric disturbance, was ordered antipyrine but was given by mistake thirty grains of exalgine, which he took in the course of three hours. A similar amount was injected on the following morning. Symptoms of vertigo, with extreme dyspnœa and pronounced cyanosis were experienced soon afterwards, and lasted for two days. The patient recovered.

ARISTOL IN VENEREAL DISEASES.

Vincenzo Fisichella (*Riforma Medica*, 1891, p. 238) has tried aristol in the treatment of simple and syphilitic chancres, buboes, mucous and gummous patches, and has arrived at the following conclusions: 1. In simple or syphilitic chancres aristol produces after a certain time a drying up of the ulcer. 2. In phagedenic lesions the drug is of some use but does not produce a curative action. 3. Compared with iodoform, it is less efficacious, and can only be preferred on account of its odorless properties. 4. It is easily pulverized and it adheres well. The author does not believe that aristol is destined to be of much use as a remedy for the treatment of syphilitic disorders.

NEW METHODS OF TREATMENT IN TYPHOID FEVER.

Dujardin-Beaumetz (*Bulletin Gén. de Thérapeut.*, December 30, 1890) studies prophylaxis of typhoid fever, and the use of intestinal antiseptics, cold baths and diuresis in the treatment of the disease.

Prophylaxis has been more benefited than has treatment by the discovery of the bacillus of Eberth. To purify water, boiling or sterilization is better than filtration. Rigorous care of typhoid patients is insisted upon; a strong solution of sulphate of copper, twelve and a half drachms to the quart, is recommended for washing sheets, water closets, etc.; a weaker solution, three drachms to the quart, is used to disinfect the nurse's hands and those portions of patient soiled by ejecta. In studying intestinal antisepsis, introduced by Bouchard, salol is preferable to iodoform, naphthaline, naphthol, etc., since it is less harmful and more efficient. Thirty to sixty grains may be given in twenty-four hours, in combination with salicylate of bismuth, if this drug is indicated.

Dujardin-Beaumetz does not regard hyperpyrexia as a part of the general condition of the disease, believing that typhoid fever can be serious without hyperpyrexia or that the temperature can be kept normal by antipyretics without decreasing the severity of the disease. He believes that antipyretic drugs decrease urinary secretion and retard elimination of the poisons produced. He finds that in sponging, enveloping in wet sheets and tepid baths, he has all the advantages of cold baths without their inconveniences. By a tepid bath he means one with a temperature of 86° to 89.6° F., making it about eighteen degrees below the patient's temperature; with these baths sedation of nervous phenomena is obtained, together with sufficient lowering of the temperature. Opposing Brand's systemization, he treats cases symptomatically; beginning with sponging, he gives tepid baths, if the temperature passes 104° F., one or two a day, lasting twenty to thirty minutes. Stimulating drinks are given patients, if needed, while in the bath. If ataxo-adymania becomes excessive, wet-packing is used instead; this pack is not continued for more than thirty seconds.

Sulphate of quinine is regarded as the drug best able to meet the general indications of typhoid, not more than fifteen grains a day being given. He does not believe that the benzoate of soda recommended by Robins increases the elimination of waste products; believing the kidneys are the best agents he gives abundant drinks, preferably lemonade made with wine, to favor diuresis.

He calls attention to the remarkable paper of Brouardel, showing the great in-

fluence of typhoid mortality on depopulation in France, the mortality in women being twice as great as in men. In studying the influence of the treatment on mortality, he finds that the difference under the various methods is trifling; in 1889, under symptomatic treatment, there was a mortality in the hospitals of Paris of 11.33 in a hundred; by systematized treatment with cold baths, the mortality was 11.28 in a hundred. The lowest mortality for the year, 7.33 in a hundred, was obtained by the combined use of quinine aud tepid baths.

Debove has shown that prudence is necessary in reaching therapeutic conclusions from the study of statistics, for by the purely expectant plan without hygienic treatment, he had a mortality the same year, at the Andral Hospital, of 9.2 in a hundred. Beaumetz believes that this success rested largely on the diuresis obtained by Debove. —*University Medical Magazine.*

CARPAINE.

A new alkaloid has recently been detected in papaw-leaves by M. Greshoff, of the Chemico-Pharmacological Laboratory at Buitenzorg, in Java. It was obtained by digesting the powdered leaves in spirit acidulated with acetic acid, removing the spirit by distillation, and treating the resulting extract with water so as to leave behind resin and chlorophyll. The aqueous solution was then shaken repeatedly with ether, and carbonate of sodium was added until an alkaline reaction was evident, The precipitate thus obtained was readily soluble in ether, and on evaporation of the ether the "carpaine" was obtained in colorless rosettes of crystals to the extent of about .25 per cent. of the leaves employed. Although the freshly-precipitated alkaloid is readily soluble in ether, when once crystallized it redissolves but slowly, so that the crystals can be purified and rendered perfectly white by washing with a little ether, but the percentage obtained is thus reduced to .15 per cent. On a large scale, the lime and petroleum method gives very good results, about .19 per cent., and would probably be preferred on the score of expense. Comparative experiments made on the young and old leaves, freed from the stalks, show that the old leaves afford when dried .072 per cent. of the alkaloid, and the young leaves .25 per cent., and that, on an average, a papaw plant can be calculated to afford thirty grammes of the alkaloid per year from the leaves. The hydrochlorate of carpaine, which contains about eighty-two per cent. of the pure alkaloid, is freely soluble in water. As yet, comparatively little is known of the physiological actions of the alkaloid. It appears, however, to act more especially upon the heart, slowing its action. The lethal dose for a fowl of five hundred grammes (one pound) weight was found to be about 200 milligrammes (three grains). In a fowl of three hundred and fifty grammes weight, no poisonous symptoms were produced with 50 milligrammes of the alkaloid; with 100 milligrammes, symptoms of poisoning occurred in ten minutes after injection into the breast muscles, but after twenty-five minutes the animal recovered its normal condition. The bird lay on its side, and breathed deeply in a jerky manner, and showed slight convulsive movements of the whole body, but no irritability was noticed. Further observations are necessary to determine the usefulness or otherwise of the alkaloid in medicine. Should it prove of utility, there can be no difficulty in obtaining it in almost unlimited quantity and in a definite crystalline condition. The alkaloid is easily precipitated from its solutions by the alkaloid reagents. The most delicate reaction is with Mayer's reagent,—iodo-iodide of potassium,—which, in a solution of 1 in 300,000, gives a turbidity, and in 80,000 parts an evident precipitate; phosphomolybdate of ammonium has its limit of reaction at 1 in 75,000 parts, picric acid at 1 in 30,000, and chloride of gold at 1 in 25,000. The alkaloid has a bitter taste, which is perceptible even in a solution of 1 part in 100,000.—*Pharmaceutical Journal and Transactions*, December 27, 1890.

CASES OF POISONING BY BROMOFORM.

Bromoform has been recommended by numerous observers, in the strongest terms, as a remedy in whooping-cough, but Dr. Nauwelaers (*Revue Mensuelle des Maladies de l'Enfance*, February, 1891) reports a case of poisoning in a child, aged 1 year and 3 months, suffering from whooping-cough, by 2 drops of a solution of 7 drachms to ¼ of bromoform, dissolved in an equal amount of alcohol, and given eight times daily.

The symptoms produced were profound stupor, paleness, coldness, complete muscular relaxation, tracheal rales, feebleness of respiration and circulation, contraction and immobility of the pupil, and insensibility of the cornea. The case proved fatal, and at the autopsy there was found slight congestion of the brain, marked injection of the

stomach and duodenum, and great increase in bronchial secretions.

In the *Provincial Medical Journal* for February 2, 1891, is a second case reported by Dr. E. Sachs, of a 4-year old child, in whom 3 drops of bromoform were ordered three times a day. In the absence of the mother, the child—doubtless tempted by the sweet taste of the mixture—got at the bottle, and drank what remained in it,—that is, about 15 minims of bromoform. Some time after, the child suddenly turned pale, and, staggering about, was put to bed. When seen by Dr. Sachs it was lying in a seemingly lifeless condition, with fixed dilated pupils, cyanotic lips, imperceptible pulse, and cold extremities. Injections of ether (Pravaz's syringefuls) and the application of a stream of cold water to the chest and back, soon brought the little patient back to consciousness, and the next day it had entirely recovered.—*Therapeutic Gazette.*

A NEW METHOD OF ADMINISTERING DIGATILINE.

A new method for the administration of dangerous drugs has been proposed by Petit (*Rev. Gener. de Clin. et de Therap.*, March 11, 1891). It consists in the preparation of a solution to serve as a vehicle, this being especially recommended for the administration of crystallized digitaline. It is made as follows:

℞ Glycerine . . . . . 133 grammes.
Distilled water . . . . 147 grammes.
Alchohol 95% . . . . q. s. to make a litre.

Every cubic centimetre of this solution represents 50 drops, so that the remedy may be administered in doses of $\frac{1}{50}$ of a milligramme. For example, digitaline could be ordered in the following manner:

℞ Crystallized digitaline . . . 1 gramme.
Glycerine-alcoholic solution q. s. to make a litre.

One drop of this solution is equal to $\frac{1}{50}$ of a milligramme of the active principle.

This method of administration presents several advantages. The solution or vehicle is somewhat viscid and consequently does not evaporate easily; it is stable and keeps for a long time.

THE LOCAL ANÆSTHETIC ACTION OF STROPHANTHINE AND OUABAINE.

Panas (*Archives d' Ophthalmologie*, March-April, 1890) draws the following conclusions from his clinical observations: 1. Ouabaine acts as an anæsthetic in the rabbit's conjunctiva, but has apparently no such effect in the human eye. 2. Strophanthine, though superior to ouabaine in anæsthetic properties, is so irritating in its effects on the human eye that it can not take the place of cocaine.

OIL OF PEPPERMINT IN THE TREATMENT OF "GRIP."

Dr. Charles L. Hogeboom, has had much greater success in treating grip when using full doses of oil of peppermint in addition to quinine, and full doses of bicarbonate of soda, than without it. He gives from five to ten drops three times a day, and sometimes more, till the worst symptoms subside. The disease may be assumed as microbic, although the germ has not been discovered. It is probably many times smaller than the typhoid bacillus, and, in consequence, may never be found.

The history of grip indicates a germ origin. It resembles, in many characteristics, other well-known germ diseases. He believes oil of peppermint to be a grip germicide. It acts with the greatest promptness and speedily dispels the most alarming symptoms, at least as far as my experience goes. The oil of peppermint is a powerful stimulant to the nervous system, particularly the vaso-motor, promoting regularity and decreased rapidity of the pulse, and relieving local congestion. It is the most diffusive of all the essential oils. These remarks are sufficient as hints to all practitioners who may care to make a trial of the remedy.—*Med. Rec.*

NITRITE OF AMYL IN CHLOROFORM POISONING.

Dr. E. Mammen, adds another case of chloroform poisoning treated successfully by the inhalation of nitrite of amyl. The facts are as follows: At about 7 P.M., Dr. M. received a message to come hastily to M. P——, who had taken chloroform and could not be awakened. The distance was about one and a half miles, and he stopped at a drug store to procure five-drop pearls of nitrite of amyl. Time of arrival was about half an hour after being called. He found the patient in a profound stupor, respirations shallow, pulse rapid and feeble. A three ounce bottle was found in his coat pocket, half full of Squib's chloroform. A telephone message to the druggist revealed the fact that he had purchased three ounces of the drug some two hours before. He had

swallowed apparently about one and a half ounce. Air was at once freely admitted to the room and to the patient, and a pearl of the nitrite given by inhalation. The effect was immediate and apparent. After the lapse of fifteen minutes, pulse again became rapid and feeble, and another pearl was used, with the result of deepening the respirations and increasing the vigor of the pulse. The same thing was repeated at lengthening intervals eight or nine times. Meanwhile, hypodermic injections of atropia were twice given, and towels wrung out of cold water dashed upon the chest. After four hours the patient awoke from his stupor, and in another hour was out of danger. Recovery was somewhat slow, owing no doubt partly to the great destruction of red blood-corpuscles, as evidenced by the extreme icteric hue of the skin, which persisted for two weeks. In my judgment this patient could not possibly have survived without the use of nitrite of amyl.—*Med. Rec.*

TREATMENT OF SWEATING FEET.

Dr. I. N. Bloom, at a meeting of the Clin. Soc. of Louisville, said that in a recent case, he had the patient bathe the feet in a solution of bichloride of mercury, 1 to 1000, morning and evening. After rubbing the surface carefully, so as to remove the dead epidermis macerated by the sweat, he directed the following course, which is partly original: A plaster sole, partly soaked in a bichloride solution, 1 to 1000, was put in the shoe. After drying the sole and placing it in the shoe, he sprinkled it with powdered boric acid. As regards the advantage of this method of treatment, there is much diversity of opinion. In this case the result was quite satisfactory. If this treatment were uniformly successful, it would point to a micro-organismic origin for the disease rather than a neurological. His experience has been too short to determine, but in many cases, especially of the lighter forms, it is of nervous origin. It is much easier to cure simple hyperidrosis of the feet than of the hands. Hebra's method, with diachylon ointment, is the only one promising any hope of success. He has tried many other means recommended by worthy men, but always had to return to the diachylon. The inconvenience of this latter method is great, but patients bear any treatment, that will help to get rid of the disagreeable disease. This is especially true of women.

COCAINE IN SMALL-POX.

Drs. Luton and Ory recommend highly the internal use of cocaine in the treatment of variola, having tried it during a severe epidemic that raged in Algiers, in November, 1889. The good effect of the remedy was shown almost immediately by a lightening of the color of the eruption and disappearance of many of the papules without becoming purulent. Even in those cases in which the papules persisted for some time there was no suppuration. One of the cases in which the remedy was tried was one of black small-pox, from which the patient recovered. The cocaine was exhibited in a five per cent. solution, of which from ten to twenty drops were given every six hours. As no pustules were formed, there was no pitting.—*Med. Rec.*

MEDICINE.

THE WHITE CORPUSCLES IN DISEASE.

A very interesting communication upon this subject, by CASTELLINO, appears in the *Gazetta degli Ospitalli*, No. 4, 1891. The author has studied the matter for a period of three years, on over a hundred patients and his researches were made in a laboratory of Genoa. The following conclusions are put forth: 1. Along with the destruction of the red cells of the blood, there is an increase in the white globules in the following diseases, which are arranged in the degree of the number of said leucocytes: Pneumonia, erysipelas, scarlatina, pleurisy and typhoid fever. 2. These leucocytes rise in number with the temperature, and, except in the cases of erysipelas and pneumonia, begin to diminish *pari-passu* with the decline of the fever. 3. In these last two cases the white cells only begin to diminish several days after the crisis is over. 4. In acute infections there is a predominance of small white globules which are finely granular with one nucleus (the leucoblasts of Löwit). 5. In leuchæmia and chronic infectious diseases, such as syphilis, malaria and lead-poisoning, there is a predominance of the large leucocytes with coarse granulations, having many nuclei without nucleoli (erythroblasts of Löwit). Many of these granules answer to the chemical and microscopical tests of fatty substances.

A CASE OF ECHINOCOCCUS OF THE LUNG.

An interesting case of echinococcus in the upper lobe of the right lung, in a girl, aged 16 years, and of a family history of phthisis,

is reported by L. Revilloid (*Rev. Med. de la Suisse Romande*, Feb'y 20, 1891). The girl had always been delicate, having suffered from pleurisy when she was three years of age; when eight years old she had whooping cough, and shortly afterwards an area of dullness over the upper lobe of the right lung appeared and was diagnosed as tuberculous. The best hygienic measures were used in treating the patient, but notwithstanding these precautions, the dullness continued to spread until amphoric breathing appeared over the whole area of dullness in front and behind. Once, when apparently enjoying fair health, the patient was suddenly seized with suffocation and uncontrollable cough, which was followed by expectoration of large quantities of white viscid fluid. The expectoration continued for three-quarters of an hour and was followed by violent vomiting. The patient became very ill; the face and extremities were cold and blue, and collapse set in. On recovery from this, the temperature went up and the pulse increased to 130. The expectoration continued and the nausea was so great that no food could be retained in the stomach. Rectal alimentation was employed. Two days afterwards rigors, with cold perspiration, came on and the expectorated matters exhibited an excessive fœtor. Then over the area of dullness, physical exploration showed the presence of a cavity; amphoric breath sounds, râles and crepitation were marked. The patient, however, in such condition, did not present the aspect of a consumptive person, and the rare smell of the sputum was that of sulphuretted hydrogen. In the sputum, through microscopical examination, were found organisms in the form of hooklets, but no traces of tubercule bacilli. The diagnosis was clearly made then. In the course of time, all signs of the infectious disease disappeared and the patient made a final recovery. The treatment consisted of the administration of deodorants and the regulation of the patient's posture in order to insure the evacuation of the cavity. It was afterwards ascertained that the girl, when a child, associated largely with pet dogs, known to be suffering from tænia, and thus the presence of the echinococcus in the patient was explained. About nine months later the subject of this case was enjoying apparently the best of health, no symptoms of tuberculosis having been observed.

Eleven physicians have each found a better "lymph" than that of Koch.

THE VISUAL DISTURBANCES IN TABES DORSALIS; AN ATTEMPT AT A COMPREHENSIVE EXPLANATION OF THE SYMPTOM-COMPLEX OF TABES.

Berger (*Arch. of Ophthalmology*, xix, 4) has here presented a very interesting paper. He finds that tabes occurring in the earliest and latest periods of life are free from severe complications. Tabes in syphilitic cases generally begins with cerebral symptoms and in non-syphilitic cases with spinal symptoms. Slight drooping of the upper lid increases from the beginning of the tabes up to the paralytic stage. When the lids of a tabetic patient are closed after a few seconds, fibrillar twitching is seen in the orbicular muscle of the lid. There is no marked difference in the relative frequency of inequality of the pupils in the different stages of tabes; it is slightly more frequent in the initial stages. A trace of pupillary reaction to light may be preserved for a long time, and this reaction disappears undoubtedly earlier than the reaction to irritation of the skin. Berger accepts Mauthner's explanation of the immobility of the pupil in tabes—that the fibres of the pupillary light reflex, lying in the wall of the third ventricle, suffer from a chronic ependymitis and a consequent sclerosis. Paralysis of accommodation becomes the more frequent the more advanced is the disease. As a rule, paralyses of the exterior ocular muscles are found disproportionately oftener in cases showing optic atrophy than in cases not thus complicated. Between the cases of optic atrophy with paralyses of the ocular muscles and those without such complications there is no special difference as regards the duration of the affection before blindness ensues. Most of the optic atrophies develop in the pre-ataxic stage; but should such atrophy develop later, blindness will follow the sooner the more advanced is the tabes. No relation exists between the contraction of the visual field, the color-fields, the disturbances of central vision, and of color-perception in tabes. Contraction of the outer portion of the visual field is most frequent, though it may occur in its upper portion. Syphilitic patients show a greater tendency to permanent paralyses of the ocular muscles than non-syphilitic patients, owing to the fact that they are more subject to multiple paralyses. Berger draws the following conclusions: Many of the symptoms of tabes may be explained by a lesion of the nerve nuclei in the fossa rhomboidalis and its continuation into the aqueduct of Sylvius. The dif-

ficult closure of the lids may be explained by a slight functional disturbance of the upper nucleus of the facial nerve. The myosis is paralytic, caused by paralysis of the vaso-constrictors in the medulla. The reflex iridoplegia is caused by a legion of the fibres running in the wall of the third ventricle to the nucleus of the sphincter pupillæ. The diminished intra-ocular tension sometimes found is the result of the lowering of the tone of the vessels. The lacrymation in tabetic patients is a vaso-motor neurosis. The sympathetic nerve is not the cause, but the medium by which certain ocular symptoms of tabes are carried from the central nervous system to the eye. In tabes it may be said in general that the nerve nuclei in the medulla nearest the median line suffer more frequently than those farther outward. An affection of the medulla is indicated by the development of diabetes mellitus in tabes, and in this manner may, perhaps, be explained the febrile symptoms which are sometimes met with in tabes. It is unnecessary to assume the existence of hæmorrhages in the central fibres and in the nuclei in order to explain the transitory paralyses of the ocular muscles which come on in the beginning of tabes. We know that the antero-lateral tract, which connects the degeneration zones of the medulla with those of the cord, contains vaso-motor fibers, and it has been proved that the lesions of the cord, especially in tabes, correspond in extent to the vasculas zones. It may be concluded from the functional disturbances of the optic nerve that vascular changes alone cause the disturbances, and the assumption is admissible that the functional disturbances of the vascular regions of the optic nerve and posterior columns of the cord are caused by a disease of the nerve centers in the fossa rhomboidalis, resulting from an ependymitis of the medulla.

Berger's experimental investigations, in which he cut different parts of the medulla, shows that: 1. Nystagmus may develop. 2. Mydriasis as well as myosis may appear. 3. As a result of injury to the medulla, hæmorrhages are found in particular vascular regions of the cord. 4. After injury to the medulla, changes in the retinal vessels may come on.—*N. Y. Med. Jour.*

REFLEX PAIN IN REMOTE REGIONS AN EVIDENCE OF INTERNAL HEMORRHAGE.

In 1880, a German, aged fifty-nine, while engaged in playing chess with Dr. H. Engel complained of an excruciating pain in his left knee, which had developed a few hours before and gradually became more intense. He had never suffered with rheumatism or neuralgia of any kind, never met with any injury, and never felt any pain in that knee. An examination gave no result; there was neither redness, swelling, nor tenderness. He went home promising to use certain anodynes as directed by me. Late in the night Dr. E. was sent for, the pain not having diminished. A hypodermic of morph. sulph., one sixth grain, gave no relief, and it was followed fifteen minutes later by a second injection of one-fourth of a grain, and the pain became less severe. The next day the pain remained about the same; he refused another hypodermic, and a blister applied at 11 A.M. Otherwise his health was undisturbed, there being no symptom or sign of any other morbid condition. Dr. E. was informed later, that the pain subsided somewhat about five o'clock in the afternoon, probably from the effect of the blister still covering the spot. A few minutes before 6 P.M. the pain again became suddenly intense; he expressed a desire to use the commode, and while sitting upon it he was seen to fall forward. An immense hemorrhage, extending over the entire base of the brain, had caused the fatal issue before Dr. E. reached him an hour later.

An Israelite, aged sixty-three, remarkably active and healthy-looking, while visiting, on the afternoon of December 14, 1884, a lady with whom he had been very intimate for years, complained of a severe pain in the left leg, a little below the knee. This pain became so severe that a neighboring physician, a homœopath, was sent for. He had the patient go to bed and administered various internal remedies. At about 9 P.M. the pain became easier, when suddenly all the symptoms of the classical apoplectic seizure developed. In this state he was removed to his home, where Dr. E. saw him about 11 P.M. Venesection, the application of croton oil to his tongue, and the internal use of tartar emetic caused him to regain consciousness; but when Dr. E. saw him the next morning his temperature was 102° and the fatal issue seemed imminent. Later in the day the hæmorrhage recurred and he died the same night.

October 11, 1886, a man of fifty-three consulted Dr. E. about a severe pain in his back. The closest examination failed to reveal its cause. It was not lumbago, for no movement of any kind augmented or diminished the pain. After several days of fruitless

medication a blister cured it. The man then remained well for three months, when the same pain suddenly returned while he was at his home on the night of January 16th. Nothing seemed to give relief, and a little after 5 A. M. death occurred from cerebral hæmorrhage.—*Med. News*, March 28, 1891.

SURGERY.

STRICTURE OF THE MALE URETHRA.

Dr. J. William White, in the *University Medical Magazine*, gives his views in an able manner as to the treatment of this condition. The following are his conclusions :

1. Strictures of large calibre, that is, of more than 15 French, situated at or behind the bulbo-membranous urethra, are to be treated almost without exception, by gradual dilatation.

2. Strictures of large calibre occupying the pendulous urethra are to be treated by gradual dilatation when very recent and soft, and by internal urethrotomy when of longer standing, distinctly fibrous in character or non-dilatable. It is to be remembered that the great majority of so-called strictures of large calibre of the pendulous urethra are merely points of physiological narrowing.

3. Strictures of the meatus and of the neighborhood of the fossa navicularis should be divided upon the floor of the urethra whenever it is evident that they are real pathological conditions producing definite symptoms and not normal points of narrowing.

4. Strictures of small calibre (less than 15 French), situated in advance of the bulbo-membranous junction, unless seen very early and found to be unusually soft and dilatable, furnish the typical condition for internal urethrotomy, which should be done preferably with a dilating urethrotome and, invariably, with all possible antiseptic precautions.

5. Strictures of small calibre (less than 15 French), situated at, or deeper than, the bulbo-membranous junction, should be treated whenever possible by gradual dilatation. In a case of resilient, irritable or traumatic stricture in this region or of stricture which, for any reason (as the occurrence of rigors), is non-dilatable, external perineal urethrotomy is the operation of choice.

6. Strictures of the deep urethra, permeable only to filiform bougies, should be treated by gradual dilatation when possible, the filiform being left *in situ* for some time, and followed by the introduction of others, or used as a guide for a tunneled catheter. If the stricture be not suitable for dilatation, external perineal urethrotomy should be performed.

7. Impassable strictures of the deep urethra always require the performance of perineal section.

IS CANCER OF A POISONOUS NATURE?

Prof. Adamkiewicz, of Krakau, read a paper before the Royal Academy of Sciences at Vienna (*Deutsche Med. Zeit*). on the above subject. After formulating the following questions, he reaches the conclusions given below in reply thereto :—

1. Is it, in the first place, possible to demonstrate any poisonous property of cancer-tissue, no matter how developed, upon the animal organism ?

2. Is the activity of the cancer-poison upon the animal dependent on the location of the site of inoculation ?

Experiments upon rabbits have so far furnished the following answers :—

1. There is a poison in recently-removed and unchanged carcinomatous tissue.

2. This poison can kill animals in a few hours.

3. It acts only on the nervous system, and death is caused by paralysis of the brain.

4. Boiling heat and disinfectants (carbolic acid, etc.) destroy the activity of this cancer-poison.

5. The micro-organisms which are constantly to be found in cancerous substance and at the site of inoculation do not, however, seem to be the carriers of this cancer-poison.

6. By transplanting cancer-tissue upon a favorable soil, the latter also acquires poisonous properties; it cannot be stated definitely to what extent the micro-organisms are concerned in the production of these properties, which develop on this soil at the same time.

7. No other living tissue, whether of physiological or pathological origin, possesses (as far as can be determined from his experiments) the poisonous properties of cancer.

8. This poison has been found only in true carcinomas ; in sarcomas and adenomas he has not yet been able to prove the existence of such a poison.

9. The action of the poison is so rapid that it may be of value as a means of rendering evident the cancerous nature of a pathological growth.

10. Tissue from the cadaver possesses a poisonous action very analogous to that of carcinomatous substance; this analogy is so great that it may be positively stated that malignant growths produce during life a material having an action similar to that of the poisons from the cadaver.

Adamkiewicz intends to produce the proofs of these conclusions in a more extended form. —*Memphis Med. Monthly.*

TREATMENT OF ABDOMINAL CONTUSIONS PRODUCED BY HORSE KICKS.

From an interesting study of the treatment of abdominal contusions produced by horse-kicks, Moty (*Arch. de med. et de Chirurg. nulit*, Feb'y and March, 1891) arrives at the following conclusions: 1. In one-third of the cases abdominal contusions of the origin indicated are accompanied by serious intestinal lesions. 2. The diagnosis of perforation is impossible. 3. The best method to use in the treatment of intestinal wounds is the direct union by means of sutures. Even if peritonitis exists, intestinal suturing and laparotomy can be practiced. 4. Meanwhile, an exploratory laparotomy is not indicated, and in the case of doubt, medical treatment alone should be resorted to. 5. In regard to prognosis, this should be withheld for about a month, for subsequent complications may arise as a result of a latent contusion of the mucous membrane.

TREATMENT OF GLEET AND SEXUAL NEURASTHENIA BY MEANS OF METALLIC BOUGIES.

Dr. Charles Szadek, of Kieff, Russia, in the *Atlanta Medical and Surgical Journal*, refers to the extraordinary difficulty of healing some cases of gleet is well known. There are men who have every morning an exudation, although they have tried every possible remedy against the evil. Frequently, especially after coitus or excess in saccho, the chronic disease becomes acute, which often leads to disagreeable results.

The product of the chronic inflammation of the urethra is an infiltration of the cells of the diseased mucous membrane; the infiltration gradually becomes fibrous tissue, which, in its turn, produces the cicitrization called stricture; the upper cells of this stratum, constantly sloughing, exfoliating and mingling with the mucous secretion of the glands, constitute the exudation which characterizes chronic gonorrhœa (gleet); the glands and lacunæ of the urethra are also affected. It is clear that many chronic gonorrhœas already represent the first stages of stricture, or, as Otis calls them "large sized strictures," which naturally cannot be cured by astringent solutions, or even such as are fatal to gonococci. If they are to be cured local pressure must be used to remove the cell infiltration, while medical treatment is adopted to affect the catarrh. For these reasons treatment with metallic bougies against chronic gonorrhœa has been mostly practiced.

In four years (1887–1890) I have treated fifty (50) cases of inveterate gleet with most satisfactory results, by the introduction into the urethra of Beniqué's duly curved tin bougies, anointed with either Unna's

Ol. cacao	1,0
Ceræ flavæ	2,0–5,0
Bals. Peruv	2,0
Arg. nit	1,0

M.; f. ung.

Or Sperling's Salve:

Lanolini	20,0
Ceræ albae	4,0
Arg. nit	0,1–0,3

M.; f. ung.

These bougies are slightly conical and eleven centimeters in length. In nervous or very sensitive subjects, in whom the assertion of the bougies gives rise to pain and erection, from 3 to 5 per cent. solution of cocaine should be previously injected into the urethra; during the first sitting the bougie is left *in situ* not longer than for three or five minutes, but later on the duration of the sittting is gradually increased up to fifteen or twenty minutes. The sittings are repeated every two or three days, except in very inveterate and atonic cases, in which a daily introduction of the instrument is advisable. I have used a set of the bougies from No. 18 to No. 30 charriere, commencing with the least irritating bougies and gradually ascending to even larger ones. In relatively recent and in old cases I have usually employed Nos. 22, 24 and 25, while in more severe and protracted ones (which, by the way, constitute a vast majority) I have passed, following Professor Otis's instance, by degrees to No. 28 or even No 30. In patients with narrowed ureter, I have enlarged the latter by means of a bistoury. In such cases where the lesions are situated in the bulbous or the posterior division of the urethra, his bougies should be introduced even as far backwards as the bladder; according to my experience, the deep insertion, when practiced with due caution and carefulness, never causes any untoward accessory effects (such as vesical or urethral irritation, urethral fever, etc.). The therapeutic results which I have obtained with this treatment are sat-

isfactory. My fifty cases of gleet, which were treated after the mechanical method in five cases of urethritis posterior, complicated with obstinate vesical affection, the results were far from being satisfactory; but in the remaining forty-five the treatment by metallic bougies proved highly successful. In thirty of the fifty cases a complete cure ensued; in another case a considerable improvement was obtained, and the only symptom left was a scanty mucoid discharge recurring from time to time. In relatively recent or in old cases from four to eight sittings proved to be sufficient for effecting cure. In a majority of cases, however, two or three months' course was necessary for the purpose, while in some unusually severe case, complicated with multiple strictures where a relapse took place, another course was to be repeated some months later.

The same method in the shape of the insertion of Nos. 20 to 30 gave to me most gratifying results, also, in fifteen cases of sexual asthenia, with spermatorrhœa and incomplete sexual impotence.

I arrive at the following general conclusions:

1. The method under consideration proves very useful; in many cases of neurasthenic irritation of the urethral mucous membrane, and in many cases of inveterate gleet, especially in those characterized by infiltration and other morbid changes in the mucous membrane and submucuous tissues.

2. It proves beneficial further in inveterate gleet of an atonic character, or in that kept up by local nervous disturbances.

3. In some cases, however, the mechanical treatment must be supplemented by a subsequent course of local astringent remedies.

4. The method is free from any untoward accessory effects; provided, it is practiced with due precautions.

THE TREATMENT OF VARICOSE ULCERS.

Dr. J. Braun states that a large experience with this class of cases has convinced him of the superior advantages of a 10 per cent. ointment of zinc in lanoline (zinc oxid. 15.0, lanoline 110.0, ung. emoll. 40.0). This is applied as follows in cases of ulcer of the legs: The surface of the ulcer is thoroughly washed with luke-warm water, carefully dried with a compress, and the salve spread on a soft piece of linen applied to the sore and retained by a handkerchief or strip of linen. The patient remains in bed until the sores have cicatrized. The good effects of this treatment soon become apparent, the pains and itching disappear, and the profuse watery secretion is arrested, the greater part of the transuded fluid being absorbed by the lanolin which has hygroscopic properties. The ointment forms a protective covering under which healing takes place, while the lanolin by virtue of its antiseptic powers prevents decomposition of the secretions. In cases of unhealthy ulcers, the application should be renewed four or five times daily for the first few days. After three or four days, the surface of the sore will be found much cleaner, and cicatrization will have occurred at the margins, and then the ointment need only be applied three times daily. Once a day, and preferably in the morning, the ulcer should be irrigated with luke-warm water and dried, and before each application any remaining secretion is removed with absorbent cotton. Since employing this treatment the author has not found it necessary to resort to skin transplantation.—*Allg. Wien. Medizin. Central-Zeitg.*

GYNÆCOLOGY.

MEDICATED PENCILS FOR ENDOMETRITIS.

Terrier (L'Union Médicale, Jan'y 8, 1891) uses the following combination for the preparation of medicated pencils:

℞ Powdered iodoform.....10 grammes.
Tragacanth gum.....9.50 "
Glycerine and distilled water each
q. s. to make 10 pencils.....

These pencils are recommended in the local treatment of simple endometritis, when direct exploration of the uterine cavity and dilatation are not necessary. The iodoform may be replaced by salol or resorcine in the same doses. If it is desired to use the bichloride of mercury, the pencils may be prepared in the following way:

℞ Bichloride of mercury.....0.50 grammes.
Pulverized talc..... 25 "
Tragacanth gum.....1.50 "
Glycerine and distilled water each
q. s. to make 50 pencils.

The vagina should at first be thoroughly washed and disinfected with a one thousandth solution of the bichloride of mercury, after which the pencils are to be introduced into the uterine cavity and retained there by the aid of iodoform or salol tampons.

TREATMENT OF FISSURED NIPPLE AND ENGORGED MAMMARY GLAND.

Dr. Barton Cooke Hirst, in a recent number of the *University Medical Magazine*, says: In the treatment of fissured nipple,

when the cracks are at all extensive, the ordinary remedies recommended from time to time have been found more or less unsatisfactory. Painting with tincture of benzoin, for instance, while an excellent procedure for small superficial cracks of the nipple, is perfectly worthless in more advanced cases.

The writer has found in hospital and private practice that excellent results can be secured in bad cases by the application of an ointment made up of equal parts of castor oil and subnitrate of bismuth. This mixture makes a very smooth, soft ointment, which relieves the pain, and is an excellent protective to the part. Before application, the nipple and surrounding skin should be carefully cleansed and disinfected, and then the ointment should be smeared on plentifully. If it is necessary for the child to nurse from the affected nipple, it can be allowed to do so without the necessity of removing the ointment from the nipple, as must be done if tannic acid or the salts of lead are used. This is a serious disadvantage of many forms of treatment recommended for fissured nipple, for the irritation of removing the substance employed as a local sedative neutralizes its action.

For the engorgement and pain in the mammary gland itself, which so often accompanies fissured nipple, the writer has had excellent results from the use of an application of lead water and laudanum, which is applied by means of a cloth covering the whole breast, renewed at frequent intervals, and kept in place by a suitable mammary binder, either that recommended by Richardson or the Murphy bandage. This not only retains the dressing, but supports the breast and exercises even pressure upon it. With this treatment the development of mammary abscess is a rare event. If the child can be nursed from the other breast alone, it is safer, I think, to draw the milk from the affected gland by means of a breast-pump, until the cure is almost complete. If it is necessary that the child should nurse from the cracked nipple, a glass nipple shield with a rubber tip must be employed.

TRENDELENBURG'S POSTURE IN LAPAROTOMIES.

The advantage of Trendelenburg's method of pelvic elevation in suprapubic operations upon the bladder has been generally recognized by surgeons. In a recent number of the *Centralblatt für Chirurgie*, Dr. Leopold states that an experience of several years has convinced him of the value of this posture in intra-abdominal operations on females, for diseases of the uterus, ovaries and tubes. By elevating the pelvis the intestines are caused to gravitate toward the diaphragm, and the pelvic organs are thus rendered much more accessible to operative procedures. As is well known the protrusion of the intestines into the wound is frequently a source of delay and danger in laparotomies; they get in the way of the operator, and are apt to be wounded. Aside from this, the posture affords an excellent view of the pelvic viscera, enabling us to recognize the presence of adhesions between the uterus and rectum or bladder; to diagnose the different forms of salpingitis and ovarian disease, and to determine the relative position of the organs. In operations before a class of students, the latter are enabled to follow the different steps of the procedure much more readily than when the woman is in the ordinary position. It is often a source of disappointment to those witnessing a laparotomy that many of the details of the operation escape observation, but Dr. Leopold assures us that by the employment of this posture, many important points in the technique, such as the manner of ligating the pedicle and the application of the sutures can be noted.—*International Journal Surgerg.*

HÆMOSTYPTICA.

Fritsch (*Therapeut. Monatshefte*, January, 1891) states that in common with all gynæcologists he uses ergot frequently in his gynæcological work. In obstetrical practice he rarely has occasion to employ it. For a long time he gave the drug in pill form as follows:

℞

Powder of ergot	80 grains.
Tragacanth	q. s.

Make 60 pills.
Take ten pills daily.

In practice among poor patients this is a desirable formula on account of its cheapness. For more prompt action he uses the following prescription:

℞

Powdered ergot	10 drachms.
Alcohol	20 drachms.
Sulphuric acid	2 drachms.
Warm water	4 pints.
Digest to	1 ½ pints.
Filter and add syrup of cinnamon	4 ounces.

Take two tablespoonsfuls three times daily.

This preparation of ergot, though very effective, will disagree with the stomach and cannot be taken continuously,

Fritsch then advises the use of Denzel's ergotine in the following combination.

℞ Ergotine (Denzel) } of each.....80 grains.
Powdered ergot }
Make 100 pills.
Take six pills daily.

In this way ergot may be given with excellent effect for a long while.

In cases of menorrhagia the following is advised:

℞ Dried extract of hydrastis canadensis }
Dried extract of gossypium } of each 80 grains.
Ergotine (Denzel) }
Make 100 pills.
Take three pills three times a day.

In the form of suppositories ergot seems to be of little value.

A tincture may be made on the plan of the decoction given above, of such strength that one drachm will contain eight grains of ergot. Of this two tablespoonfuls may be given daily. Fritsch calls this *tinctura hæmostyptica.*

This tincture is very effective, especially in menorrhagia after labor, at the climacteric and in profuse menstruation of the very young. This remedy should always be tried before any operative measures are undertaken for the relief of menorrhagia.—*University Med. Magazine.*

SEXUAL LIFE OF WOMEN AFTER CASTRATION.

At the Berlin Medical Congress, Dr. F. Deppler, of Venice, read a paper embodying the results of a study he had made in the cases of ovariotomy performed by himself. He had performed castration forty-six times, obtaining a cure in thirty-nine. These operations were performed for the relief of purulent or gonorrhœal salpingitis, oöphoritis, fibroid tumors of the uterus, etc. The following were his conclusions, derived from a study of the physiological consequences of these operations: 1. When the operation was performed on account of salpingitis or other inflammatory process, uterine hæmorrhage never occurred subsequently. 2. The conjugata became gradually shortened, and this was the more marked the younger the individual was when operated upon. 3. The uterus became atrophied, the vagina grew shorter and narrower, its mucous membrane became paler, and the labia majora were somewhat thinned. 4. The breasts grew smaller, acquiring a strong resemblance to the male mammæ. 5. The brown pigmentation of the nipple, areola, perineum, and annus disappeared wholly, as did also pathological pigmentation existing in some of the cases; the hair also turned white. 6. The tendency to embonpoint, which is generally believed to exist after these operations, was not observed by the author. 7. No changes were observed as regards the growth of the hair or the tone of the voice. 8. The sexual desire remained, and was the more pronounced the earlier in life the operation was performed. 9. The operation offers no impediment to marriage; three of the author's cases had married and had lived happily with their husbands for years. 10. A marriage with a castrated woman is the ideal Malthusian marriage, and the only way the Malthusian idea can be carried out without endangering the health and happiness of the woman. 11. In the cases operated upon in early life for inflammatory conditions, no neuroses were seen to develop, which was not the case when women were operated upon late in life for fibroid tumors of the uterus. 12. A favorable influence upon the hæmorrhage was observed after operation for myoma, yet in no case did the menopause at once set in. 13. In cases of operation for uterine fibroma, the patients, even those in full maturity, lost all sexual inclination after the operation.—*Medical Press and Circular.*

OBSTETRICS.

INDICATIONS FOR OPERATION IN ECTOPIC GESTATION.

Dr. C. A. L. Reed, of Cincinnati, Ohio, contributed a paper to the *Southern Surg. and Gyn. Assoc.*, on this subject.

The paper starts with the assumption that the only proper treatment of ectopic gestation is by laparotomy, or, more properly, cœliotomy. While the profession has become practically unanimous that this is the proper line of treatment, the indications for operation have been less definitely decided upon. This conviction is forced upon the observer, not only by a study of the literature of the subject, but by encountering cases which have been advised against operation by their attending physicians, until hæmorrhage within the pelvis has threatened a fatality, which is but too frequently realized. The most legitimate excuse for this dilatory practice is to be found in the confusion which has arisen with regard to the supposed uniform causal relationship of ruptured ectopic gestation to pelvic hæmatocele, and the division of the latter into "primary" and "secondary" rupture. These terms are unfortunate, and, as used in this connection, may be entirely arbitrary. Primary rupture is made to mean rupture beneath the peritoneum, instead of first rupture, as the etymology of the word would

imply, while secondary rupture is made to mean rupture within the peritoneum, instead of "second" rupture; whereas an intra-peritoneal rupture may be, and frequently is, a primary rupture, when spoken of with reference to the sequence of events in ectopic gestation. There would be no serious confusion here if we were not also taught to leave extra-peritoneal hæmatoceles alone, to be taken care of by absorption, and if we did not add that, as these hæmatoceles are generally caused by ruptured ectopic gestation sacs, we are to relegate these cases also to the expectant plan of treatment. This conclusion is without warrant, and is responsible for hundreds of deaths annually from this one cause.

The treatment of ectopic gestation premises the diagnosis of this condition. This is obviously difficult, and in the majority of instances cannot be arrived at at all, or, if at all, only presumptively. But in all these cases conditions can be found in the pelvis, which, if not conclusive of extra-uterine pregnancy, yet constitute conclusive indications for exploratory operation. The presumption of ectopic pregnancy can be arrived at before rupture, chiefly by a history of previous sterility, by a previous amenorrhœa, followed after a few weeks by irregular hæmorrhage, by increased tumefaction at each side, or behind the uterus, and by the existence of false decidua within the uterus. The latter fact may be safely determined by the judicious use of the Emmett curett forceps. The diagnosis after rupture is essentially the diagnosis of internal hæmorrhage. Time wasted either to determine the cause of that hæmorrhage, or to find out whether it be primary or secondary, is criminal. The thing to do is to cut down and operate. The position has been taken that time should be taken for the patient to rally from the shock. One of Dr. Reed's own cases died simply because he waited twelve hours for reaction—a lesson which taught him the fallacy of the old teaching, and which has since saved lives at his hands. The best way to overcome shock from internal hæmorrhage is to stimulate the patient by giving ether, stop the drain by ligating the bleeding vessels, and arouse the nervous system by washing out the belly with hot water.

What shall be done with the appendages on the other side? In view of the fact that tubal pregnancy generally depends upon desquamative salpingitis, as confirmed by the recent observations of Formad, before the American Association of Obstetricians and Gynæcologists, and in view of the fact that this disease is almost uniformly bilateral, the question is at once raised, "Is the woman liable to an ectopic pregnancy on the other side?" Herman, in the *British Medical Journal*, September 27, 1890, reports such a case; and Tait reports another, with death from rupture of the second conception. Leopold Meyer reports another, and refers to verified cases by Veit and Olshausen. There are now at least ten cases on record. From this Dr. Reed concludes that if the patient's condition at the time of the operation is such as to justify further interference, the appendages from both sides should be removed.

He submitted the following conclusions:

(1.) The only proper treatment of ectopic gestation is that by abdominal section.

(2.) The operation should be done in cases before rupture as soon as the condition can be presumptively diagnosed.

(3.) The operation should be done in cases after rupture, as soon as the evidences of internal hæmorrhage become apparent.

(4.) In cases in which the period of viability has already been reached without rupture, pregnancy should be allowed to advance to term before operation, but only under the closest possible vigilance.

(5.) In all cases the appendages from both sides should be removed, providing the condition of the patient will justify the extension of the operation.—*Ann. Gyn. Pæd.*

THE TREATMENT OF ECLAMPSIA.

Dr. Barton Cooke Hirst (*Ann. Gyn. Pæd.*) in considering the various methods employed in the treatment of eclampsia, says that he believes that a careful analysis of the different plans of treatment will award the palm to chloral, with diaphoresis and catharsis, anæsthetization and occasionally venesection. Morphia, it is true, gives the best record—3.3 per cent.—but this was in the hands of a single individual, and his report would be more impressive were it more exact. Thus, he says that in "more than thirty years" he has had "more than sixty cases of eclampsia." In that period one's memory could easily play him false, both as to the number of cases and the results. Chloral, on the other hand, has achieved brilliant results in different hands aud places He should like to see veratrum viride more extensively tried, and would be glad to unite with others holding hospital positions to give it a thorough test under favorable conditions. He believes the results would be excellent—would, perhaps, challenge those of chloral. But as the case

stands at present, it seems to me that the conscientious physician must depend upon chloral, at least in private practice, until the equality or superiority of some other plan of treatment is proved. Perhaps a combination of chloral and veratrum, one by the bowel, the other hypodermically, will give better results than either remedy alone. This he intends to test at the first opportunity.

PÆDIATRICS.

INSOMNIA IN INFANTS.

Dr. Jules Simon considers insomnia a symptom of much importance in infants. In many diseases it is a sympton of minor importance, and of no special interest. In others it is one of the chief manifestations of the disease. The influence of dentition has been greatly exaggerated. Unless congestion of the gums or surrounding parts is present, it causes but little disturbance of the sleep. Dyspepsia and indigestion are the most common and universal causes of disturbed sleep, even without the definite symptoms of vomiting, diarrhœa, or marked constipation. A discussion of the treatment would involve a review of the whole subject of dietetics. Causes referable to the nervous system probably occur next in frequency. All young infants may, even in the first year, present evidences of acute cerebral congestion. Extremes of either cold or heat may produce the same result. A child that has been exposed to a strong wind during its daily airing, or one that has had insufficient protection from the sun, may pass a restless and uncomfortable night. This condition must be distinguished from the insomnia of meningitis which, in some cases, is for many days the only sign. In older children, headache due to overtaxing of the brain is not uncommon. Anæmia and rapid growth, in conjunction with over-study, is a fruitful cause of insomnia. In children of rheumatic parents this tendency is especially marked. Among nervous causes in these older children, hysteria, chorea, and epilepsy are the most common. The young hysterical subject is always liable to insomnia, with or without headache. Some attribute all headaches of this period to hysteria, but the author believes that the distinction should be carefully made between such headaches and those due simply to rapid growth and over-study. The insomnia of epilepsy is peculiar to itself, and is sometimes the only symptom for a considerable period. The child suddenly wakes from profound sleep, sits up, and begins to cry, but soon lies back, as if exhausted, and falls into a deep sleep. These attacks are always accompanied by incontinence of urine. Insomnia complicating chorea is an exceedingly grave symptom. Earache is always accompanied by insomnia, and usually by continuous crying. Hernia is a cause of pain and sleeplessness that is frequently overlooked. Intermittent fever is in some cases marked by wakefulness at a definitely recurring period. Insomnia and headache are prominent and early symptoms of albuminuria.—*New York Medical Journal.*

DIAGNOSIS OF TUBERCULOSIS IN CHILDREN.

In the March No. of the *Rev. Mens. des Malad. de l'Enfance*, M. Mirinescn calls attention to the existence of enlarged lymphatic glands in various parts of the body, such as the axilla, groins and others, as affording great assistance in making the diagnosis of phthisis in children, especially in doubtful cases. If the child is in an emaciated and weakened condition, and there are no superficial lesions to explain the enlargement of the glands, it may be inferred that tuberculosis is present. Out of sixteen cases of this nature examined, the glands of fifteen were found, by experimental inoculations, to be tuberculous. This "peripheral polyadenitis" as the author terms, it, may be observed in children as young as fourteen or fifteen months.

THE ANTIPYRETIC TREATMENT OF FEBRILE AFFECTIONS OF CHILDREN.

In the yearly report of the Children's Hospital of Berne, Professor Demme publishes a number of rules as to the selection of antipyretic measures in the treatment of various febrile affections in children, and his results, which are exceptionally valuable, in that he has rich experience, are published in the *Wiener Medizinische Blätter* for January 1, 1891.

In the first place, Dr. Demme maintains that he is firmly convinced that, in children, febrile affections, with moderate fever, from 100° to 101° F., are best treated without any antipyretics whatever in the way of therapeutics, and that the febrile symptoms may be best controlled by cloths wet in cold water and wrapped around the trunk. His experience, he states, has taught him that such moderate febrile temperatures, with the accompanying nervous excitement and restlessness and the insomnia, or still more alarming profound somnolence, can be more

satisfactorily overcome by baths of from five to ten minutes' duration each, administered twice daily, the temperature of the water being from 79° to 82½° F. When, however, the temperature reaches 104°, and remains at this elevation, then antipyretics are necessary, although the author shows that there is the greatest choice in the selection of a suitable remedy for this purpose. Regard must not only be paid to the elevation of temperature alone, but also the character of the morbid process and the condition of the patient's strength must come into consideration. His experience, he states, has taught him that typhoid fever, acute articular rheumatism, and broncho-pneumonia of asthenic type best respond to the antipyretic therapeutics. He rarely, however, employs them, or only exceptionally when compelled to, in diphtheria, in the acute exanthemata, such as scarlet fever and measles, and in simple croupous pneumonia. What was said above as to the employment of baths alone applies also to the combined employment of antipyretic drugs and baths. He only recommends the employment of baths when the temperature of the body is reduced during its administration in extremely rare cases and only when there is an alarmingly high temperature. In the large majority of cases, luke-warm baths, of the temperature above referred to, more or less prolonged in administration, will give much more satisfactory results. In cases where the soporific symptoms are especially marked, and where there is deep red or light cyanotic color in the face, luke-warm baths may be used and are better taken at about 40° F., poured over the head and neck. As regards the selection of the individual antipyretics, in addition to the general observations already given in every case of acute articular rheumatism, when the condition of the digestive organs permit it, he uses the salicylate of sodium, or, where there is a tendency to vomiting or diarrhœa or serious objection to the taste, he substitutes for it salol. Of the salicylate of sodium, the following are the doses to be administered in twenty-four hours: For children from 2 to 4 years of age, 7½ to 15 grains; for children from 5 to 10 years of age, 15 to 30 grains; for children from 11 to 15 years of age, 30 to 45 grains. The following are the doses recommended of salol: For children from 2 to 4 years of age, three times daily, a powder of 4 to 5 grains; for children from 5 to 10 years, three to four times daily, a powder of from 7½ to 12 grains; for children from 11 to 15 years of age, three to four times daily, a powder of 12 to 15 grains; and in typhoid fever he has found the greatest satisfaction upon the employment of thallin, administered in the form of sulphate, giving it every two hours to children from 3 to four years of age in doses of ⅛ grain; from 5 to 10 years of age, in doses of ¼ grain; 11 to 15 years of age, in doses of ½ to ¾ grain. In cases of broncho-pneumonia, where the temperature may often reach 106°, antipyrine is the remedy which Dr. Demme recommends, giving it dissolved in large quantities of water, with the addition of a little sugar and a few drops of brandy. In this mode of administration he claims that disturbances of the appetite or vomiting will be entirely avoided. He states that this remedy has rarely failed to give him satisfactory results where he has attempted to produce marked reduction of temperature, notwithstanding cases of broncho-pneumonia, or in the acute exanthemata, or even in malignant diphtheria, and he consequently prefers it to any one of the other antipyretics. He recommends the following doses, to be taken at hourly intervals: For children of from 2 to 4 years of age, 3 to 6 grains; from 5 to 10 years of age, 7 to 12 grains; 11 to 15 years of age, 13 to 15 grains. Of course, when the antipyretic effect commences, this dose must be diminished, while larger doses are, according to the author, never required. In cases of broncho-pneumonia in children, where hectic fever sets in, with high evening exacerbations and morning remissions, antipyrine, or any of the aromatic order of antipyretics, will be of value. The dose which he then administers is, for children from 11 to 15 years of age, 12 to 15 grains; although the author, as seen, gives the preference to antipyrine as an antipyretic, he nevertheless refers to acetanilide and antifebrin as likewise, in cases of erysipelas and acute rheumatism and pulmonary tuberculosis, satisfactory antipyretics, while antifebrin possesses the advantage over antipyrine in more seldom leading to the production of exanthematous eruption.—*Therap. Gaz.*

STATISTICS AND TREATMENT OF DIPHTHERIA.

Statistics as to the cases of diphtheria and croup treated in the Children's Hospital of Pesth are given by Dr. Johann Bokai (*Wien. med. Woch.*, No. 10, 1891) for the years 1889-90. There were 447 cases of diphtheria, and 32 of "primary laryngeal croup." Post-diphtheria palsy was noted in 10 per cent. of the cases. The mortality

among the 447 cases of diphtheria, of whom one quarter were under three years old, was 234 (54 per cent.); in 170 cases the larynx was not affected, and the death-rate in this class was only 23 per cent. Laryngeal croup occurred as a complication of faucial diphtheria in 237 cases; 53 cases recovered, 32 without, and 21 after, tracheotomy, which was performed 159 times. In the group of 32 cases of uncomplicated laryngeal croup, 16 cases recovered; 7 without, and 9 after, tracheotomy, which was performed 23 times. The treatment adopted in pharyngeal diphtheria was the internal administration of chlorate of potassium, gargling with lime water, and painting two or three times a day with a 5 per cent. solution of perchloride of iron in glycerine, which Bokai believes prevents the occurrence of laryngeal complications. After tracheotomy steam inhalations were continuously used, and perchloride of mercury internally. Sulphate of copper was used as an emetic, and was of great value in the early stages of laryngeal croup, but the prolonged use of emetics was dangerous. Tracheotomy was resorted to when suffocation was imminent; the operation, in Bokai's opinion is contra-indicated in septic cases, and in those in which the symptoms point to involvement of the bronchi. In the discussion which followed the reading of Bokai's paper at the Buda-Pesth Society, Professor Gerlóczy stated that 157 cases of diphtheria had been treated in the Rochus Hospital with a death-rate of 43.9 per cent. Dr. Glass spoke favorably of treatment by Löri's method; this consists in burning about three-quarters of a pound of sulphur in a room, at the end of four hours ventilating the room four or five minutes, and then placing the patient in it; an adjoining room is then prepared for the patient in the same way.—*Brit. Med. Jour.*

INTUBATION OF THE LARYNX IN DIPHTHERIA.

Dr. J. Mount Bleyer, of New York (*Archives of Pediatrics*, March, 1891), gives the results of 512 cases of intubation of the larynx for croup and diphtheria operated on between 1886 and 1890; of these cases, 37 per cent. recovered. The 512 cases included 294 males and 228 females. The ages varied from 6 months to 21 years; 251 cases were under 3 years of age, with 73 recoveries; 260 were over 3 years of age, with 115 recoveries. Of 4 cases, 6 months of age, all died; of 7 cases, 9 months old, 4 died; of 3 cases, 10 months old, 2 died; of 14 cases, 12 months old, all died; of 48 cases, 2½ years old, all died. In cases of recovery the tube was removed on the first day in 5 cases; second day in 29 cases; third day in 37 cases; three days and a half in 14 cases, fourth day in 43 cases; fifth day in 22 cases; sixth day in 10 cases; seventh day in 13 cases; ninth day in 6 cases; tenth day in 4 cases; eleventh day in 3 cases; fifteenth day in 2 cases; twentieth day in 2 cases. Among the causes of death in the 322 fatal cases, extension of the false membranes occurred in 67 cases; bronchitis in 45 cases; pneumonia in 41 cases; broncho-pneumonia in 40 cases; sepsis in 39 cases; asphyxia, due to closure of the tube by membrane, in 2 cases. The author strongly emphasizes the necessity of making a forced or a normal laryngoscopic examination before operating, as the differentiation and diagnostication of other laryngeal diseases may be made out, and the extent of the diphtherial or croupous lesion seen. The tube is to be extracted daily for the purpose of removing any accumulation of loose membranes, tenacious mucus, pus, etc. "When the tube has been extracted, irrigate the posterior nares, pharynx, larynx, and entire surface with a mild solution of bicarbonate of sodium." Much of the success depends upon the judgment of the operator in selecting a suitable tube. When loose membranes exist in a case, a tube of thinner metal and larger calibre is recommended, and is left *in situ* for six hours or more. The tube once in place, the most vital portion of the treatment must be next carried out, namely irrigation of the affected parts. A No. 8 soft rubber catheter attached to a fountain-bag syringe, is passed into the nostrils alternately, and a solution of the peroxide of hydrogen (5 ounces of a 15 volume solution, chemically pure, in 12 ounces of water) is passed through; after this has been done, the next step is to wash out the mouth, pharynx and larynx. If necessary, a gag must be used; the patient is held well forward over a basin for the reception of the returning fluid. For purposes of comparison, the recorded results of tracheotomy operations are given as follows: German authors have obtained 31 per cent. recoveries in 5,795 cases; German hospitals record, 30 per cent. recoveries in 3,063 cases. French surgeons have tabulated 9,242 cases, with 24 per cent. cent. recoveries. In the Boston City Hospital between 1884 and 1887, 327 operations yielded 29 per cent. of recoveries. Out of 21,853 cases collected from all sources by Dr. Lovett, of Boston,

29½ per cent. of recoveries were obtained.—*Brit. Med. Jour.*

HYGIENE.

THE BACILLI OF MALARIA.

Dr. Andreas has recently published an interesting treatise on the comparative number of the bacilli of malaria in the air at different times of the day. His experiments, which were conducted in the Observatory of Moncalieri, and reported in the *Medicinische Neuigkeiten*, April 11, 1891, were carried out by means of small rubber balloons filled with hydrogen. On to these balloons he fastened a small box, holding prepared glass slides, which box he was able to open by means of a cord, after the balloon had reached the desired height. Microscopical examination of the slides showed that in the early hours of the day the swarms of bacteria were close to the ground and in large numbers; later, at about nine o'clock in the morning until about three in the afternoon, they would rise until they reached a considerable height, and from that time would again gradually sink to the ground. The number of bacilli in the air was almost exactly in proportion to the rise of temperature, while in direct opposition to the amount of humidity in the atmosphere. It is evident, therefore, that the condensation of the watery vapors in the air cause the falling of the bacilli, and for this reason the morning and evening hours are the most dangerous in malarial districts.

INFECTION THROUGH THE SOIL.

The question is often raised whether there is any direct or indirect proof of the infectivity of the bodies of those dying from specific fevers, or whether the soil of graveyards may become really dangerously contaminated thereby; but it is also one to which comparatively little attention has been given by the experimentalist. One aspect of the matter has been lately studied by Dr. Justyn Karlinski, of Konjica, Herzegovina; in a series of experiments (*Centralblatt f. Bakteriol.*, ix, 13) undertaken to determine whether the organs of the body undergo any change in temperature during the natural process of decomposition after burial in the earth, and especially whether any differences in this regard are to be met with in the case of infected subjects. His results show that invariably the putrefactive process is accompanied by a rise of temperature above that of the circumjacent soil; and also that this rise in temperature is markedly higher when the parts examined have been taken from the bodies of men or animals who have succumbed to infective diseases than it is in the case of healthy bodies. He further examined into the question of the survival of the pathogenic bacteria in the affected parts, and states that the typhoid bacilli may retain their vitality in the decomposing spleen for three months, and are only completely annihilated by rapid putrefaction and the presence of a large number of the bacteria of putrefaction. Dr. Karlinski says that he had previously shown that typhoid bacilli could retain their vitality for a period of five months in soil, but that if the earth were thoroughly saturated with rain water they were destroyed in from seven to fourteen days. The part played by the soil in the origin of epidemics should not, he thinks, be underestimated, since typhoid bacilli can only exist in water a comparatively short time.—*Lancet.*

INFECTION FROM MILK.

In the *Glasgow Medical Journal*, for October, appears an account of an epidemic of erysipelas and sore throat, occurring among families supplied with milk from a certain farm. The most striking symptom was an intense inflammation of the fauces, resembling erysipelas of the mucous membrane, with swelling of the glands of the neck, and in some cases suppuration. In some, true erysipelas of the skin developed. The temperatures ranged from 102° to 105° during the first few days of an attack. Convalescence was attended by extreme prostration. No bacterial examination was made, but a clear connection was traced between the milk and the epidemic.—(*Jour. Amr. Med. Asso.*)

THE ETIOLOGY OF TETANUS.

In the last number of the *Annales de l' Institut Pasteur*, there appears (from the Bacteriological Laboratory of Val-de-Grâce) a most interesting paper on tetanus by Drs. Vaillard and Vincent, which appears to throw very considerable light on the subject of tetanus, and to clear up a number of points and observations that have hitherto been enshrouded in obscurity. After describing the organism, and identifying it with that already made familiar through the papers of recent writers, the authors give it as their firm opinion that in cases of artificial inoculation of pure cultures it is always the poison introduced along with the bacillus, and not the organism itself, that acts upon the animal.

This indeed seems to be probable, as they are able to prove that almost inconceivably minute doses of this poison, which they compare with snake poison, are quite sufficient to produce all the symptoms of most acute tetanus; in fact, it was almost impossible, from some of the cultures that they obtained, to administer a dose that was not lethal.

An exceedingly interesting feature brought out in the course of their work is that in no case was the poison developed as soon as the organism began to grow; in fact, gelatine cultures of the tetanus bacillus were never capable of producing toxic symptoms until liquefaction of the gelatine had commenced, when spores were demonstrated to have been formed, and when the peculiarly disagreeable odor so characteristic of tetanus cultures had become perceptible. They associate both the odor and the peptonizing power with the formation of the poison in the cultures. That it was due merely to the presence of the spores that the material was poisonous they demonstrated by heating their cultures to a temperature of 62° C., for a short time (a temperature which is quite incapable of interfering with the vitality of the spores), when it was found that cultures so heated and introduced by inoculation into a rabbit or a guinea-pig failed to produce any tetanus, thus proving that although the spores are not killed the poison has been destroyed by the heat. The spores were proved to be living by making fresh cultures from them in artificial media; after a time they grew luxuriantly, and if left to grow eight or ten days produced another crop of the poison. By simply washing away the poison from the spores with distilled water they also obtained similar results, for, although the spores could still develop and form the specific poison in artificial media, they were, when inoculated, incapable of giving rise to any symptoms of tetanus. From the reaction to heat of a substance they were able to separate, and from its resemblance to the diastases in other respects, they conclude that they have obtained from tetanus cultures the true tetanus poison, a poison, however, that cannot be formed by the tetanus bacillus in healthy tissues. The microörganisms are here so rapidly attacked by the leucocytes that they are rendered *hors de combat* before they have time to form their poison.

It has long been well known that the tetanus bacillus could not develop in the tissues except, apparently, in the presence of other organisms, and the suggestion is offered that these other organisms act in one of two ways; they either paralyze the activity of the leucocytes, or they draw off, as it were, their attention and activity from the tetanus bacillus, thus allowing it sufficient time to develop its characteristic products. It is interesting to note that Drs. Vaillard and Vincent consider that in many respects the tetanus bacillus is extremely like the diphtheria bacillus, the method of action on and in the organism being essentially the same in the two cases, the above factors in all probability playing a part in diphtheria much as in the case of tetanus; and it is evident that in studying the one poison much light may be thrown on the other. Behring and Kitasato appreciated this fact, and combined their forces to work out the question of immunity in these two diseases. It is obvious, however, from a consideration of some of the points that are indicated in this paper, that there are many sources of fallacy that will have to be eliminated before the ultimate explanation of the condition of immunity in protected animals can be given. The facts that this poison is active in such extraordinary minute quantities, and that the microörganisms are able to grow with such difficulty in the human tissues, allow us to hope that extremely minute changes in the blood may be quite sufficient to secure the alteration or breaking-down of the virulent poison, even when it has become diffused throughout the system. So long as the organism is localized to the wound, there is, of course, more chance of coping successfully with the disease, although here, as in other diseases, there always appears to be a possibility of the poison exerting such a paralyzing influence on the cells that usually take up foreign substances, that secondary septic conditions may be liable to occur even when the action of the tetanic poison can be antagonized so far as its primary effects on the cells are concerned. One question appears to be set at rest, and that is, as regards tetanus and diphtheria, the ptomaines have had their day, whatever may become of the products of other organisms. It may be accepted that here, at any rate, we have some subtle poison which, although it has not yet been actually separated, has become so far isolated that it may be taken as proved that it is not an alkaloid or basic poison. A most remarkable feature is that, in peptonizing gelatine with the filtrate from a meat-broth culture of the tetanus bacillus, the poisonous properties are lost to a certain degree in direct proportion to the amount of gelatine that is peptonized; this, taken in conjunction with the fact that the properties are not developed until the gelatine begins

to liquefy, has led Drs. Vaillard and Vincent to suppose that the same agent that peptonizes the gelatine is the active agent in bringing about the development of the toxic symptoms of tetanus.—*The Lancet.*

THE REPUTED CAUSE OF INFLUENZA.

Dr. Tezzier, of Lyons, France, claims that influenza is produced by a microbe, which he styles the strepto bacillus, whose habitat is putrid mud. That Russia is its home is, in his opinion, due to the fact that bad drainage, filthy streets and neglected barnyards are the rule, a condition particularly aggravated by swollen rivers and generally wide plains.

BACILLI IN SYPHILIS.

Dr. von Marschalko, who has been working in the pathological laboratory of the Buda-Pesth University at the subject of the bacteriology of syphilis, has devised a method of staining by which bacilli may be found in syphilitic growths of various kinds, such as papules on the skin, the indurated base of a chancre, and condylomata, as well as in the secretion of primary sores, while he has not been able to find them in non-syphilitic growths or in the secretion of soft chancres. Whether they are really inseparably connected with syphilis can, of course, only be decided by a prolonged series of observations, but there would at least appear to have been a *prima-facie* case made out for further investigation. The method employed is by double staining, as follows:—The object, after having been hardened in alcohol, is immersed for thirty-six hours in an alkaline solution of methyl blue; it is then rinsed well with water, and re-stained by a concentrated solution of vesuvin in water. The bacilli are stained blue, and can be easily distinguished from the tissues, which are brown.

HINTS ON DISINFECTION.

Dr. von Esmarch has innumerated some of the points that should be specially attended to in the use of disinfecting apparatus. He agrees with most authorities that steam, either circulating or under pressure, and without the admixture of air, is by far the best means of disinfecting clothing and other articles that will withstand the action of moist heat. As to whether circulating steam or steam under pressure is best, he thinks that it is entirely a matter of convenience, but it will be readily understood that where large chambers have to be constructed it would be difficult and extremely expensive to build them of sufficient strength to withstand any great pressure from within. Even in the case of smaller sterilizing chambers, the expense of obtaining them sufficiently strong is so great that in most cases their use is precluded. The main desiderata for a perfect disinfecting apparatus are that it shall be close to the source of the steam-supply; that there shall be sufficient steam developed to fill it thoroughly, and to keep up the temperature for some length of time; that the steam shall be sent in at the top and passed out at the bottom, in order that every crevice of the apparatus may be filled; and that where it is used in large establishments, it shall be placed between two rooms, into one of which articles to be treated are to be taken, and passed in at one door of the sterilizer; while the other room should be at the other end of the sterilizer, and into it the clothes should be passed, so that they shall not again be brought into contact with unsterilized clothing, etc. Articles that are to be disinfected should not be allowed to remain too long in contact with steam, and before being steamed they should be thoroughly heated, so that there is no opportunity for the steam to condense on cold surfaces, and in the same way they should be well dried by heat after the steaming process has been concluded. Twenty minutes is quite long enough to allow most ordinary articles to remain exposed to a moist heat of 212° F., so that they should be left for this length of time after the temperature has once been raised to this point, this being determined by an electrical contact thermometer, or a thermometer placed in a tube through which the steam escapes; some simple manometer should be used to determine the pressure that has been obtained by super-heating the steam. The greatest attention should be paid to this point of time of exposure, for it is the experience of all medical officers of health that nothing deters people from sending their clothes to be sterilized so much as the fact that they are frequently ruined by too long an exposure to the action of the steam. Discrimination must also be used in determining what articles can be safely steamed, and an officer of health who ordered stamped plush, leather, skins, or waterproof material to be exposed to heat would render himself liable to be heartily laughed at by all practical men. Grease should always be removed if possible before the articles are put into the sterilizer, otherwise it becomes fluid and is liable to spread to other parts.—*Hygienische Rundschau.*

MEDICAL CHEMISTRY.

THE PHENYL-HYDRAZIN TEST FOR SUGAR.

Havilburg (*Centralbl. für klin. Medicin*, January 31, 1891), of Rio de Janeiro, proposes a modification of the Fischer-Jaksch test for the presence of sugar in the urine, which he considers more reliable. Two parts of phenyl-hydrazin hydrochlorate and three of sodium acetate are added to half a test-tube ful of water, to which a like quantity of urine to be tested is added. Instead of boiling over a water-bath the mixture is shaken with chloroform. In a little time the fluids separate. If sugar be present canary-yellow crystals appear in the upper layer. The reaction is more striking if the fluid is boiled a permitted to cool before the addition of chloroform. Havilburg suggests that the procedure might be adapted for use as a ready means of quantitative determination of the amount of sugar present.—*Amer. Jour. Med. Sci.*

THE PRACTICAL VALUE OF THE ALPHA-NAPHTHOL TEST FOR SUGAR.

Posner and Epenstein (*Berlin. klin. Wochenschrift*, Feb. 23, 1891), reviewing the details of this test, consider it to be free from many of the objections raised against other tests for sugar. It depends upon the fact that a solution of sugar, in the presence of pure concentrated sulphuric acid and a solution of alpha-naphthol, gives a violet-colored reaction, due, according to Udransky, to the separation of furfurol. This reaction occurs not only with sugars but with all carbohydrates and certain albuminoids; hence, the urine must be free from albumen. The test is extremely sensitive,showing one-hundredth of one per cent. of sugar. The reagents and glasses must be chemically clean. It was noted that normal urine, *i. e.*, urine which showed no presence of sugar by any of the accepted tests, gave with this test the reaction of such intensity as to indicate the presence of two-hundredth of one per cent. of sugar. The authors do not discuss the cause of this occurrence, deeming it sufficient to state that if the urine is diluted at least twenty times, this reaction is not obtained in normal urine. Hence, in practice the urine must always be previously diluted. The quantitive analysis for sugar by this method does not give perfectly accurate results in the decimal figures of the percentage. The authors conclude that the test is a valuable addition to practical medicine.—*Univ. Med. Mag.*

TEST FOR PURE ANTIPYRINE.

According to Dr. Gille, in the *Deutsche Medizinal Zeitung*, April 13, 1891, pure antipyrine may be tested by the following methods: (1.) The concentrated watery solution of antipyrine should have no effect either upon red or blue litmus paper. (2.) Pure antipyrine melts rapidly when exposed to heat, and gives off inflammable gasses, without leaving any unmeltable deposit or carbonated residue. (3.) One gramme of pure antipyrine should be entirely taken up by one gramme of water or alcohol. (4.) Sulphurretted hydrogen throws off no deposit in a watery solution of antipyrine.

A NEW POISON IN CHEESE.

Dr. V. C. Vaughn announces a new poison found in cheese. A number of samples of the suspected cheese, which, it was alleged, had caused nausea and vomiting, were examined at the hygienic laboratory, of Michigan University. Its poisonous character was proved in experiments on animals by its causing death in a few hours, but the nature of the poison could not be determined further than that it was not tyrotoxicon and that it belonged in the list of so-called poisonous albumens.

A NEW TEST FOR ALBUMEN AND OTHER PROTEIDS.

Dr. John A. MacWilliam gives in *The British Medical Journal* a method of testing for proteids by salicyl-sulphonic acid. Take a small amount of urine (for example, 20 minims), preferably in a very small test-tube, and add a drop or two of a *saturated* watery solution[1] of the reagent. If the urine is strongly alkaline, an extra drop or two of the acid should be added, and if no opalescence or precipitate occurs it is well to test the reaction with litmus paper, and make sure that the urine has been rendered strongly acid. On adding the reagent, shake the tube quickly so as to mix its contents. Then examine at once. The occurrence of an opalescence or cloudiness *immediately or within a very few seconds* (for example, 2 to 3 seconds), is a test for proteids intermediate in delicacy between the cold nitric acid test on the one hand, and the acetic acid and heat test (in favorable circumstances) on the other. The development of an opalescence some time after (for example, ½ to 2 minutes), is a more delicate test than even acetic acid and heat, and shows the presence of

[1] It is important to notice that the solution must be a saturated one in order to obtain the best results.

minute traces of proteid, which are probably insignificant from a clinical point of view as a rule.

Next heat the tube to the boiling point. If the precipitate or opalescence is caused by the ordinary "albumen" (albumen and globulin) commonly present in albuminous urine, it does not disappear on heating, but, on the other hand, becomes markedly flocculent. But if the precipitate or opalescence is due to the presence of albumoses or peptones, it clears up on heating (before the boiling point is reached) and reappears when the tube cools.

NEWS AND MISCELLANY.

OUTSIDE PHYSICIANS CAN ADMIT PATIENTS TO THE PHILA. POLYCLINIC HOSPITAL.

As evidence of the liberal spirit with which the Philadelphia Polyclinic Hospital is managed, it has been decided that the full privileges of the wards, private rooms and suite of operating-rooms may be extended by any member of the staff to physicians not connected with the institution.

Many physicians who are not attached to Hospitals have frequently cases that they would like to have under the auspices of a Hospital with its resident physicians, trained nurses and sanitary regime, and yet wish them under their own observation.

Patients thus admitted to this Hospital are attended by the physician for whom the case is admitted as fully as though he were a member of the staff. The admission blanks must invariably be signed by a member of the staff, who thereby assumes the responsibility for the acts of the physician, after which arrangements and terms may be made with the matron.

Visitors are cordially invited to visit and inspect the Hospital, on Lombard street, west of 18th, on Mondays from 3 to 4 P. M.

MUTTER COURSE OF LECTURES ON SURGICAL PATHOLOGY.

Prof. Roswell Park, of Buffalo will deliver the remaining four lectures of the Mütter Course, in the Hall of the College of Physicians, of Philadelphia, N. E. Cor. 13th and Locust Sts., on May 12, 13, 14, and 15, at 8.15 P.M.

Subject: Surgical Bacteriology. The medical profession are cordially invited to attend.

A SIMPLE METHOD OF REMOVING A NEEDLE.

I think it may be of service to record a simple means by which I obtained the removal of a broken needle from the heel of a young girl, aged 12, whom I saw lately walking about on her toes to avoid her right heel, into which a needle had been broken, touching the ground. The buried end could be felt, but any pressure led to its further entry. I directed her to wear a large thick corn-plaster around the spot, with a little wet cotton-wool in the center, and to tread freely on the heel. Within a week afterwards she showed me the needle, which had protruded, and she had easily withdrawn it. Thus no wound was made, and no scar left to be a tender spot on the plantar surface.—*Chas. Steele, M. D., F. R. C. S., in Brit. Med. Jour.*

ALCOHOL AND DIGESTION.

From experiments made on himself by Dr. Eichenberg some further knowledge of the effect of alcohol on digestion is obtained, which contrasts strongly with the teetotal lecturer's experiment showing how digestion in a glass vessel is retarded by alcohol. Dr. Eichenberg found that a small dose of strong alcohol—*e. g.*, brandy—shortens the time that food in general, whether animal or vegetable, or a mixture, remains in the stomach by more than half an hour. A similar but not quite so marked an effect is produced by a dose of diluted hydrochloric acid or mustard. Pepper and condurango diminish the time the food remains in the stomach by about a quarter of an hour. Beer and an infusion of rhubarb had no effect.

An enterprising lady has been making investigations upon the question of matrimony in regard to her sex. She finds that the highest marriage rate is among trained nurses, and impartial observation would rather tend to support the statement that this is the best field for matrimony which the fair sex enjoys.

A French dispensing chemist points out that a mixture of bromide of sodium and hydrochlorate of cocaine results in the alkaloid being precipitated. It will be well to bear this in mind, for, with the cocaine merely suspended, a serious and, in an infant, even a fatal accident might easily result.

WILLIAM R. WARNER & CO.'S

PIL. CHALYBEATE COMP.

IN THE TREATMENT OF

LA GRIPPE.

FORMULA:—Carb. Protoxide of Iron, gr. ijss. Ext. Nux. Vom., ... gr. ⅛

ADVANTAGES:—Does not constipate, is easily absorbed, is nerve tonic and quickly soluble.

The effects left by La Grippe are marked Physical Prostration for which Pill Chalybeate Comp. (Warner & Co.'s) is almost a specific. The assimilable iron, acting as a blood tonic and the Nux Vomica as a stimulant to the spinal cord.

Dose, begin with one pill every four hours and increase to two pills three times a day.

The acute symptoms of La Grippe are controlled by (**EFF. ANTALGIC SALINE**), one dessert spoonful of which contains 4 grains Antipyrine and 4 grains Salicylate Soda. Physicians will not be disappointed in the treatment of La Grippe by trying this salt followed by PILL CHALYBEATE COMP. as above mentioned.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

CLINICAL LECTURE.

ONE OF THE SEQUENCES OF LAPAROTOMY —RETROVERSION OF THE UTERUS— THE USE OF PESSARIES.

BY H. MARION SIMS, M. D.,

PROFESSOR OF GYNÆCOLOGY AT THE N. Y. POLYCLINIC, VISITING SURGEON TO SAINT ELIZABETH HOSPITAL, &C., &C.

Gentlemen:—The patient I present to you now, illustrates a condition following laparotomy, which is of a peculiarly trying nature to both the physician and the patient. This woman has a very interesting clinical feature in her history, and as she presents a condition you may be often called upon to treat in gynæcological practice, I shall give it to you in detail.

To begin with, this patient's original trouble commenced with a constant and persistent pain throughout the pelvic organs, of a most exaggerated character, which was accompanied by a very severe dysmenorrhœa. She had, in addition to this, pains in the back, headache, and all the symptoms such patients usually have, but in a most aggravated form. When she first came to this clinic for treatment, I found that on digital examination the dysmenorrhœa in her case was due to a diseased condition of the tubes and ovaries. There existed what is known as an apoplectic condition of the ovaries, with total occlusion of both tubes. I sent her to the Hospital and there performed abdominal section, under the strictest antiseptic precautions, removing both tubes and ovaries, with the result of a marked and decided improvement in every respect in her general condition. She was on the eve of being discharged from the Hospital, perfectly cured, when I accidentally discovered a small fistulous opening in the line of the abdominal incision. On passing down a probe carefully through this opening, I found that the instrument was deflected to the left in the direction of the former seat of the left ovary, and extending to a depth of six or seven inches in all. I immediately suspected the cause of the trouble to be an attempt on the part of nature to throw off the ligature that had been placed around the pedicle of the ovary that had been removed from that side, and, on passing a long forceps through this fistulous opening I very readily grasped something with its blade which I knew by the sense of touch to be the suspected ligature. This I then brought away with the forceps. It was exactly in the same condition as it was when first introduced. The fistulous opening on that side healed up immediately.

The fistulous opening on this side of the abdomen had no sooner healed up than another one developed on the right side, due to the same cause, but which was not so easily removed as in the former instance. Through this opening I passed a small-sized curette down to the bottom of the sac to the depth of about eight inches. I could readily make out by touch the existence of a foreign body, occupying the same relationship to the stump of the right ovary as was the case with the left one. Withdrawing the curette, I then thrust the forceps down the fistulous tract and I could readily grasp the ligature with it. I made traction on the ligature with the forceps, but this threw the patient into a paroxysm of such acute suffering that I was compelled to desist from any further attempt in that direction, and postpone the operation for another day. Finally, after three weeks of futile attempts at this kind of work, with the patient tired and myself discouraged, I thought I would make another attempt, in a somewhat different manner, to remove the offending ligature. I accordingly put the ligature on the stretch, and with a small probe for a guide, locating the end of the ligature, I cut the ligature completely away with a blunt-pointed bistoury. The fistulous opening soon afterwards healed promptly and the patient experienced no further trouble in that direction.

I mention this incident to you to-day in connection with the case of this woman be-

cause it is not an uncommon occurrence following a laparotomy, and is one with which you should become familiar. The ligature would never have spontaneously come away in this case, and there would be as a result a very disagreeable, running fistula.

Now, the next question that naturally suggests itself to our minds in this case is, how are we to get this fistulous opening healed up as rapidly as possible? The opening in the case of this woman was originally eight inches in depth, but it is now only three and a-half, and is gradually filling up with healthy granulation tissue. She complains of considerable weakness, slight flushing of the face, a tired feeling, and other symptoms of a like nature. I have told her that all these symptoms were due to the fact of the removal of both ovaries and tubes, and the same condition is brought about by their removal as if she had undergone a practical change of life. The proud flesh you see collected about the margin of this fistulous tract will have to be removed, and the simplest and readiest way to accomplish that is by means of the curette under cocaine. And when the normal tissue is reached, the tract will then heal up quite readily. It may also be packed with iodoform or bichloride gauze, or what is better still, applications of pure carbolic acid may be made to the entire fistulous tract, and the parts then dressed with bichloride gauze, as I have done in this case.

I wish to say a word, in this connection, about the form of ligature that should be used in these cases. The ligature I generally employ, is silk, as I consider it the strongest possible form of ligature that can be used for this purpose, and is, at the same time, the most reliable. You can be certain it will not give away, or be absorbed like catgut. The only trouble I ever experienced in my life, was in the use of catgut in a patient with a lacerated cervix and perineum. I employed catgut for suturing the cervix, putting in four stitches, and to my great surprise, on the third day after operation, I was called to the patient's bedside and found her with a profuse and exhaustive hæmorrhage from the circular artery; the four catgut sutures having come away, leaving the wound in the cervix gaping widely. Since that time I have never employed catgut in these operations, as catgut is always apt to come away, but silk never.

RETROVERSION OF THE UTERUS.

The next patient comes to us complaining of a train of pathological symptoms that one very frequently hears at clinics of this kind. She has a constant and distressing backache, persistent headache, and dragging down pains across the small of the back, which have existed for a considerable length of time. She also complains of a very obstinate form of constipation.

As I examine this woman's uterus, I can readily understand the reason for the continuance of these disagreeable symptoms. She has a uterus that is somewhat retroverted, and in making an examination for this condition, I always first ascertain the degree of mobility of that organ, whether it be freely movable, laterally as well as antero-posteriorly, and whether it can be lifted out of its position and restored to its normal relationship in the pelvic cavity. When we have found out these different conditions, we will then be able to determine what we can do for the patient.

To ascertain whether a uterus can be elevated, it is not always necessary to employ a uterine elevator for that purpose, but with a cervix so short as this is, I do not think we can get sufficient leverage manually on the anterior lip, without the use of an elevator. A good many gynæcologists do not believe in the use of an elevator for this purpose, and there are also some who argue that retroversion is not a disease *per se*, but a symptom. I do not, myself, consider displacement of the uterus a disease, but it gives rise to certain reflex symptoms, which can be removed by restoration of the uterine organ to its normal position in the pelvic cavity. I have seen so many of these patients benefited by this simple manœuvre, that I always have recourse to it when such a condition is possible. If there be adhesions formed around the uterus, you can very readily determine to what extent they are present when you pass your finger into the rectum of the patient. Under such circumstances, it may be necessary to break up these adhesions under ether, and without subjecting the patient to the risk of a laparotomy. This can be readily and easily done by means of the uterine elevator, with the patient at home in bed. After the operation is completed, she should be kept in bed for from three to six days afterwards. During that time I always make it a practice to watch her carefully, and if she complains of any pain or tenderness about the pelvic region, I treat her for these symptoms by hot douches, warm anodyne applications, and other measures appropriated for such cases. If you are careful in your operations about the uterus, you will never experience

any trouble as a result thereof.

After breaking up the adhesions in this way, I elevate the uterus a few times, to educate it, so to speak, towards assuming its normal position in the pelvic cavity. Finally, after repeated efforts in this direction, when the uterus can be readily raised without giving the slightest pain or discomfort to the patient, I then proceed to use cotton tampons or a pessary, or whatever I may deem best adapted to the case in hand.

Speaking of pessaries in this connection reminds me of the fact that twenty years ago, when I began to first practice the art of gynæcology, every one was speaking of pessaries, while to-day, among gynæcologists, we very seldom hear a pessary referred to. I do not think the time will ever come when this instrument can be safely relegated to the back shelf in gynæcological practice. If there is one subject, more than any other, that has been abused, that subject certainly is the use of the pessary. The pessary has undoubtedly, caused a good deal of harm in many instances, but I contend that this harm has been due to the flagrant abuse of this instrument, and not its use. We have many patients who come to us like this patient before us, suffering from a chronic condition of retroversion, who have been very materially benefited by the reposition of the uterus and its maintenance in its normal anatomical position in the pelvis by means of a well-fitting pessary. A pessary, no matter of what kind it be, whether it be a tampon of cotton, or one of tin or rubber, certainly does give great relief to the patient in a large majority of cases. In the fitting of a pessary there is at times as much mechanical ingenuity required of the physician as in the making of any mechanical appliance. The instrument must fit "just so," to be worn with any degree of comfort. It must neither press back in front nor at the sides. In fact as much care should be taken in the fitting of the instrument as a dentist would take in the fitting of a plate in the mouth. If the patient complains of undue pressure or pain caused by the instrument at any point, it should be removed at once, and the patient herself should be instructed how to remove it in case it gives her the least discomfort

In fitting a pessary for displacement the method I always employ is to first map out in my mind the exact shape of the vagina, its length, its breadth and its general outline. I then take one of these Sims' block tin rings, which, as you see, is perfectly malleable and can be bent into any desired shape. I recommend these rings to you because of their ready adaptability to any case and because you can make almost any one's pessary out of them; they are to be furthermore recommended, because if the pessary is an instrument you need only occasionally, you will find these rings very much cheaper than a rubber pessary, and a dozen of them will answer the purpose of five or six dozen of the others. They are, therefore, very much more economical for an ordinary practitioner or a country doctor to carry for gynæcological practice. I take this medium sized block tin pessary and mould it in my hand until I think that this curve I have given it posteriorly will suit the required purpose. The width I give it by gently pressing in the hand and the slight curve downward which I give it anteriorly, is done for the purpose of preventing a too firm pressure against the pessary.

I will now proceed to place this pessary in position, and this is best done with the patient lying on her back. By making firm pressure downwards with one index finger on the perineum, you see that the instrument is readily slipped into position by the uterine elevator. The next step is to let your patient get up and walk around the room, in other words, to test the instrument fully before allowing her to leave your office. If she complains of pain at any point, remove the instrument at once and find out the exact point of pressure and where the fault lies with the instrument. Having made the necessary alterations in the instrument, replace it then and you will find it will be perfectly comfortable. Never permit a patient with a newly adjusted instrument to go away and remain for several days from under your observation. Always instruct her to return the very next day so that you can be sure the instrument is doing no harm, or else, if she lives at too great a distance to return the following day, then instruct her how she is to remove it herself in case it causes her the slightest inconvenience or the least pain.

Now, this block tin pessary is not to be applied in this case as a permanent instrument by any means. Being made of block tin, it is apt to corrode and to cause at the end of a few weeks sore spots on the mucous membrane of the vagina. Consequently, I only use it as a temporary instrument to get the proper shape of what will subsequently be a permanent one. When the block tin instrument fits satisfactorily, as you think it ought to do, you can then remove it, send it by mail to the nearest instrument maker and

have him make you a hard rubber one, of exactly similar kind, or, if you have any mechanical ingenuity about you, you can take the hard rubber one and with the aid of a spirit lamp and a little vaseline or sweet oil, mold one into the required shape.

Having now adjusted this pessary in the patient before us, you see that it holds the uterus up perfectly, the patient complains of no pain whatever, her backache has gone, and I have no doubt but that after wearing the instrument a few weeks, her general health will be in every way very much improved. She will be able to go about her work and attend to her duties as she has not been able to do for some years past.

The next patient I present to you illustrates, very strikingly, the points I have just given you in regard to the management of adhesions around the uterus. This patient came here some months ago with the uterus bound down on all sides by firm bands of adhesions, which I have broken up under ether, in the way I have just pointed out to you, until the uterus was rendered freely movable, and after two or three weeks of local treatment it has been kept in its normal position in the pelvic cavity by means of a Thomas Smith pessary. She came here with exactly the same symptoms and condition as the patient I have just spoken to you about, and she is now entirely free from all the symptoms that accompany retroversions. She wears the pessary without the slightest inconvenience, and is hardly aware of the fact that she is wearing one at all. A pessary is worn with advantage only in one way, and that is when it gives rise to no pain whatever from its use.

Bear in mind the fact that there is no one pessary that will fit any two patients, and each instrument must be molded to suit each individual case. Mold your instrument to fit your patient and do not try to mold your patient to fit the instrument. When you have fulfilled these anatomical indications you will then know how to fit an instrument correctly so that your patient will be able to wear it with a great deal of practical comfort and satisfaction.

Synthetical Quinine.—MM. Grimaux and Armaud have succeeded in producing a quinine by synthesis which is said to be in every respect identical with the quinine of vegetable origin. They arrived at this result by treating a base obtained from the *Remijia Pedunculata* (cuprein) with sodium, and heating the compound thus obtained with chloride of methyl.

CHRONIC GASTRITIS—GASTRIC ULCER—ATROPHY OF THE GASTRIC MUCOUS MEMBRANE.[1]

BY J. P. CROZER GRIFFITH, M.D.,

PROFESSOR OF CLINICAL MEDICINE IN THE PHILADELPHIA POLYCLINIC; ASSISTANT PHYSICIAN TO THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

Gentlemen.—The first case that I shall show you is interesting and practically very useful to study. The man is one of those individuals from whom it is difficult to obtain an entirely satisfactory account of himself. He came here a week ago, with a history somewhat as follows: He is 39 years of age, married, and an iron-worker by occupation. He has had the ordinary diseases of childhood, except whooping cough, and suffered from measles only a few years ago. With these exceptions he has been practically well until within a year and a half. Then, for causes unknown to himself, he began to feel weak and out of health, and afterwards to lose flesh. He also began to experience pain in the epigastrium and a sensation of distress on eating, but he did not have much vomiting until last Autumn. During the summer he imbibed stimulants in rather large quantities, but it does not appear clear whether this habit was the result of fondness for drink or of an effort to overcome the weakness. In November he commenced to vomit nearly every day, and often several times a day. For the past three weeks he has not been troubled so much in this way, although he still vomits frequently. The pain which he suffers comes on at no regular period as related to the time of the ingestion of food, although it appears to be food which produces pain. Neither does the vomiting occur at any difinite time. There has been no history of ejection of large quantities of food, or of blood; nor has there been in the vomited material any particularly dark substance, further than could be explained by the character of the food taken. The bowels have recently been constipated, though formerly they were regular. He does not know what articles of diet disagree with him most. After a general mixed meal he is apt to suffer pain and distress. At times he can restrain the vomiting for hours, but eventually he is forced to yield to the inclination.

This, gentlemen, is the history in brief.

[1] A Clinical lecture delivered at the Hospital of the University of Pennsylvania.

It is not very perfect, but it is the best we can get out of him. It is not typical of anything, but it is interesting in connection with the case which was before you last week.

You probably remember that anæmic girl who suffered intense epigastric pain, coming on soon after eating, and shooting through to the back; while vomiting occurred very soon after the ingestion of food. Ulcer of the stomach was naturally suspected, for this is apt to occur in females of about her age.

It is quite certain that patients often have no marked gastric symptoms and yet may have an open ulcer in the stomach. Again, it has been found that certain patients, after suffering from the symptoms of ulcer, appear to recover entirely, and go on for an indefinite number of years without further gastric symptoms, and then relapse. Or they may evidently die of some other disease, and at the autopsy an ulcer may be found in the stomach entirely unhealed. It has probably been open, but inactive all these years.

We therefore may have an ulcer without any characteristic symptoms, and again an ulcer present with severe symptoms; the symptoms later disappearing, although the ulcer has not healed.

The girl of whom I have been speaking says that for a long time she has not passed more than two or three days without vomiting. For the past week she has been at absolute rest in bed, and has been on an exclusive diet of peptonized milk in small quantities. She has not vomited since she entered the hospital. She feels better and her health is improving. This shows what rest and proper food, in proper quantity will sometimes accomplish.

A very important matter to be borne in mind in her case, was the condition of her blood. We found on examination that there were 2,900,000 red blood cells to the cubic millimetre. That is, taking 4,500,000 as the normal number for females, she had 64 per cent. of erythrocytes. The amount of hæmoglobin, however, only equalled 20 per cent. There is therefore a marked contrast between the percentages of hæmoglobin and of red blood cells. The girl really has chlorosis or chloro-anæmia, and it is conceivable that the pain in her case is simply of the nature of a cardialgia, a common symptom in chlorosis, and that there is no ulcer. It is equally possible however, and much more probable in the light of the very marked gastric symptoms, that an ulcer does exist which is the indirect result of chlorosis; since it is a very well-known fact that this disease acts as a powerfully predisposing cause of ulcer of the stomach. The presence of chlorosis modifies the treatment to some extent. It has been found that in order to effect the healing of a gastric ulcer, it is often first necessary to remove the chlorosis or anæmia. Consequently in addition to the rest and careful diet of which I spoke, the girl has been taking iron. Now nearly all of the preparations of iron are irritating to a stomach in this condition, and it is most important to choose one which is entirely free from this disadvantage. Within a few years a number of preparations of iron have been devised for which this property is claimed. The one which I have employed in this case is the Liquor Ferri Albuminati, the solution of the albuminate of iron, made by Drees, of Bentheim, Germany. It is of neutral reaction, entirely free from metallic taste, does not coagulate albumen, and is usually perfectly well borne by the stomach. Even in cases in which hæmatemesis has recently occurred, the use of this preparation is not contra-indicated. The girl of whom I have been speaking, takes it readily. It may be given in doses of 10 drops, three times a day at first, but a much larger amount can later be administered.

To return to the case of the man still before us. You observe that he is considerably emaciated, rather pale, yet with no decided cachexia. He is quite weak and is able to walk but a short distance. His other symptoms I have already reviewed.

There are several diseases to be taken into consideration in the diagnosis of his case. One is gastric ulcer; a second is chronic gastric catarrh, or chronic gastritis which is practically synonymous; a third is carcinoma ventriculi, and a fourth is simple dilatation of the stomach. Gastric ulcer can be readily excluded by comparing this man's symptoms with those of the girl. The pain does not come on so soon after eating, it is not as intense and is not as localized as in ulcer. The vomiting, too, is not so prompt, and there is, indeed, very little connection in this case between the time of eating and that of vomiting. There is another very important matter,—the chemical characteristics of the gastric contents—to which I shall allude in a few moments.

Simple dilatation of the stomach, *i. e.*, a dilatation not due to carcinomatous constriction of the pylorus, may produce a degree of anæmia and emaciation which is surprising.

I do not know that I have often seen cases more emaciated than sometimes after simple gastrectasia, where the stomach seems for various reasons to have lost the power of emptying itself of food and has dilated to a remarkable degree. This condition can be recognized in various ways. One plan, proposed by Ewald, rests on the use of salol, of which 5 or 10 grains may be given at one time. Salol is supposed not to undergo decomposition into salicylic acid and carbolic acid until it reaches the intestinal juices. By having your patient pass his urine every fifteen minutes and testing this with chloride of iron, you may, by observing the brown coloration, determine how soon salicylic acid appears in it. Where the stomach is inactive the salol may remain in it for hours or days. If, after the administration of salol, you can in the course of half an hour detect salicylic acid in the urine, you feel assured that there is no motor insufficiency. It is however necessary to say that the value of the salol reaction is much disputed by various observers, and is still problematical. The test may be a help in forming a diagnosis, but cannot be relied on as conclusive. We have not yet had an opportunity of trying it in this patient.

Another method of determining the presence of dilatation is by percussion. It is, however, often very hard to be positive as to the different percussion boundaries of gastric resonance. The liver covers the lower portion of the right boundary, and the left border, also, cannot be located with certainty. The upper border is partially covered by lung. After all, these boundaries usually vary but little in any case. It is the determination of the lower boundary which is the important matter. It is this which you wish to find in gastrectasia, and having found it, the others can be disregarded. You will find in practice that it is frequently, perhaps usually, not easy to distinguish the tympany of the stomach from that of the colon and small intestines. The ability to do this in any case depends a great deal upon the respective amount of gaseous dilatation of the various viscera. By simple percussion it is often impossible to fix the lower limit of the stomach. Where there is great dilatation you may find a loud, deep-toned tympany in the gastric region, and you may get the succussion splash on tapping with the tips of your fingers. Some writers, indeed, claim that the production of the succussion splash, and the noticing the regions in which this ceases, is the best method of outlining the stomach under all conditions. I think, however, that you will find it much more difficult than the description would indicate. The lower boundary of the stomach could of course, be located by passing a sound and feeling for it through the abdominal walls, in the way proposed by Leube; but this method is by no means without danger, and is unpleasant to the patient. Another plan is that of Penzoldt, namely, the passage of a tube, the pouring in of water through this, and the determination by percussion of the position of the dullness produced. This method is reliable, but unpleasant, and not free from danger, should an ulcer exist. A third method is that of Frerichs. This consists in allowing the patient to drink, say, 20 grains of bicarbonate of soda, dissolved in a glass of water, and to follow this by another glassful, containing about three quarters as much tartaric acid in solution, with a little sugar to take away some of the sour taste. Chemical decomposition at once begins, carbonic di-oxide is set free, the stomach dilated by it, and the limits of the viscus often very distinctly defined both to inspection and to percussion. The method is, nevertheless, not entirely accurate and sometimes disappoints utterly; since for its success, is required a decided ability on the part of the pylorus to restrain the gas from passing rapidly into the intestine. One must also be prepared to withdraw the gas promptly with the stomach-tube, in case unpleasant symptoms arise. Perhaps the simplest plan, and the one to be first employed, is that of Piorry, of which Penzoldt's method is a modification. This consists in causing the patient to drink several glasses of water and then in determining the lower border of the percussion dullness while he is in the erect position. This, of course, indicates the lower boundary of the stomach. On again reclining, this line of dullness shifts.

The lower border of the stomach varies considerably in its position, since, as we know, the stomach itself is a movable organ. It is however, the very generally accepted opinion that the lower boundary of the healthy stomach rarely reaches to the transverse umbilical line, and that, when it extends much below this line, the viscus is certainly dilated. In the present case, however, it is easy to determine that the stomach is not dilated, and I will not take the time to go through the examination with you.

The two diseases remaining for us to consider, are chronic gastric catarrh and cancer.

I have said nothing about dilatation from cancerous constriction of the pylorus, for there

is no dilatation in this patient. We have still to entertain the possibility of the presence of a carcinoma of some other portion of the stomach, interfering with health by disturbing the digestion, causing pain and giving rise to cachexia. It is very difficult in this case to determine whether the patient is suffering from gastrititis or from cancer. There is one sign whose presence would put the diagnosis beyond doubt. If we were certain that we could find some increased resistance, some nodular growth in the epigastrium, we should be justified in concluding that we had to do with carcinoma. If we found it in the region of the pylorus we could not certainly tell that it was located in the stomach, for it might be in the left border of the liver. Growths in the liver are, however, almost invariably of secondary nature, so that if you find severe gastric symptoms accompanying a growth which appears to be in the liver it is probable that you also have to do with a primary tumor in the stomach, whether you can detect it or not. In a case in which you were in doubt whether the tumor felt was in the liver or the pylorus your diagnosis would be aided by observing the effect of respiration. The liver moves a great deal with respiration. Hence, if such a patient breathe deeply and the tumor simultaneously move downward some distance you would be inclined to believe that it was in the liver. If, however, you can move it about pretty freely in the abdominal cavity, and it move but little with respiration, you would conclude that it was not in the liver.

To illustrate the difficulties often attending the recognition of a gastric cancer by palpation, I may tell you of a case in this hospital some years ago. The man was examined by several expert observers. All agreed that in the epigastrium, and extending into the left hypochondrium, there was a distinct mass, undoubtedly a carcinoma ventriculi. I examined him also and had no doubt of the correctness of this diagnosis. The patient suffered from progressive emaciation and cachexia and from marked gastric symptoms. After some months of repeated observation he died. At the autopsy a small growth was found in the *colon*, and the rest of the tumor was composed of fecal accumulation merely. I well recall the first—I fear not the last—time I failed to recognize such a mass. It was the case of a man admitted to the hospital in which I was then an interne. On examining him I found what I supposed to be a large growth extending over the left side of the abdomen. On the suggestion of a fellow-interne I administered a large dose of salts and the growth promptly disappeared. Since then I have always hesitated to diagnosticate any growth in the abdomen unless I was sure that the bowels had been opened regularly, and even unless I felt pretty confident that no hardened fecal accumulation existed around which softened feces could pass.

In the case before us there is no evidence of a tumor at the pylorus. I am not quite sure that there is not a sensation of increased resistance elsewhere in the gastric region, but I think it very probable that this sensation is purely subjective. It is so easy to feel something when you are looking for it.

You will find the greatest difficulty in your practice in palpating the abdomen. It takes, I think, much more experience than does the physical examination of the chest. One of the chief difficulties consists in overcoming the resistance of the abdominal muscles. Sometimes you find the abdominal walls lax, and then palpation becomes an easy matter, when, however, the patient is very fat, or the muscles very resisting you are often practically at sea and can determine nothing. If the case be one in which a decision is absolutely necessary you might give ether. This would help greatly, but it is, of course, not feasible in every case. In ordinary practice you direct the patient to draw up his legs in bed, and you may even prop him up slightly in order to still more relax the abdominal parieties. Then have him breathe deeply—sigh—through his mouth. In this way, and by gentle and skillful palpation—and only long practice after all can teach you this—you will usually succeed in determining the conditions present. Sometimes, however, it will be only after several examinations that you finally satisfy yourself.

This man has no positive evidence of cancer. There is no increased resistance determinable with any certainty, he has no marked cachexia, and he has been working very hard though sick, which accounts for much of his weakness. He could scarcely have had a cancer for the past year and a half and be in as good condition as he exhibits at present. Since he has been in the Hospital he has had no vomiting. He has been in bed and has been fed on peptonized milk. We have also given him pepsin with hydrochloric acid and wine of condurango. The latter was proposed some years ago as a

specific in cancer. It is, of course, not such, but it is an excellent stomachic, similar to tincture of cardamom.

I think, therefore, that in this patient we must make the diagnosis of chronic gastritis, in the production of which, at any rate in the increasing of which, the excessive use of alcohol has had some influence.

I have as yet merely referred to the chemical examination of the contents of the stomach in gastric diseases. This is now-a-days a most important matter. Many investigators have maintained—and perhaps most prominent among these is Riegel—that in cases of cancer of the stomach free hydrochloric acid cannot be found by certain color tests, some of which I shall presently mention; whereas in gastric ulcer the secretion of hydrochloric acid is always in excess. Further, that most cases of dyspepsia, including many cases of chronic gastritis, do not suffer from a diminution in the amount of acid secreted, but rather from an excess of it. The whole subject is still in what might be called a formative stage. What is stated positively and apparently proved by one investigator, is as positively contradicted or disproved by another. A few points, however, I think, we may depend upon. First, that in gastric ulcer the amount of free acid found is almost always in excess, or at any rate not diminished. Second, that in cases of gastric cancer free hydrochloric acid is always absent, or at any rate present in very small quantities. I do not think, however, that we are at all justified in concluding that the absence of free acid is met with only in cancer. Although many cases of chronic gastritis are characterized by an increase in the amount of acid secreted, in other cases of the same disease, and in some other gastric affections as well, the secretion is certainly diminished or absent.

The absence of acid, then, only increases the probability of the existence of cancer in cases in which the other symptoms point strongly in that direction. I should, however, hesitate to make the diagnosis of cancer if hydrochloric acid were present in normal amount, or of ulcer if the acid were absent.

Most of you are familiar with the way in which we procure the contents of the stomach. The patient is given a mixed meal in the morning, and, if you wish to be very accurate, the stomach should be first washed out. Five to seven hours afterwards syphon out the contents of the stomach with a tube, using as little water as possible. Some clinicians use no water, but simply introduce the tube and, having the patient lean forward, press firmly over the epigastrium, and thus force the contents out. I have never been able to do this with much satisfaction, but have always needed a little water. The contents of the stomach, having been secured, are filtered and examined by various chemical tests. We wish to ascertain several things. Among these are the presence and amount of lactic and butyric acids which indicate the degree of fermentation. Further, the presence of free hydrochloric acid, as this is to some degree an index of the digestive power of the stomach. You need not look for pepsin, as it has been found that where hydrochloric acid is secreted, pepsin is secreted also. You may, however, readily test the peptic strength by placing a small cube of hard-boiled white of egg in a test tube with some of the filtered fluid, and setting this in a warm place for six or eight hours. If the fluid has no peptic strength the egg does not change; otherwise it is, of course, more or less dissolved.

A very important matter which is, I think, unduly overlooked by many writers, is the presence of peptones. It is easily conceivable that a man may have no excess of pepsin and hydrochloric acid but quite sufficient to make abundant peptones of the food taken. You may find in such a case no hydrochloric acid and no peptic strength, but testing with sulphate of copper—the biurette test—may show an abundance of peptones, indicating that acid and pepsin must have been present at some time during digestion. A case of this nature was in this Hospital only a few weeks ago. I examined the contents of his stomach and found no hydrochloric acid or peptic strength, but a decided re-action for peptones. At the same time there was no reason to suppose that the patient had a cancer of the stomach. An interesting case showing the value which sometimes attaches to these newer methods of clinical study was that of a man who was for a time in the Hospital some years ago. He suffered from marked and increasing anæmia, emaciation and gastic symptoms. He was given a very carefully regulated diet, and his vomiting and distress ceased, but he continued to fail in health. The question arose whether or not a carcinoma ventricoli was at the bottom of all his trouble. To some who examined him it seemed that there was increased resistance on palpation of the epigastrium. However, chemical examination of the gastric secretions showed abundant hydrochloric acid and powerful peptic strength. On this ground the idea of carcinoma was abandoned. The case finally developed into one of pul-

monary tuberculosis, and after death there was found a duodenal ulcer, but no cancer.

Now, in the patient before us to-day examination has shown that the free acid is entirely absent, and that the secretion has no peptic strength. Are we then compelled to altar our diagnosis? I think not. As I have already told you chronic gastritis is sometimes without free hydrochloric acid in the gastric contents. We shall then remain by our previous diagnosis. We will continue his treatment and report his progress on another occasion.

I wish to say a word here in reference to the tests employed for hydrochloric acid. There are a number recommended and the battle over their respective reliability wages as fiercely as that over the indication of free acid when found. The tests perhaps oftenest employed are the methyl-violet, the Congo red, and the Phloroglucin-vanillin or Günzburg reaction. The latter is rather more difficult to apply, and I do not know that it is any more accurate or reliable. The tests generally used in this Hospital are Congo red and methyl-violet. If a solution containing free hydrochloric acid, even if very dilute, be added to a solution of the former the red becomes a blue. With the latter the violet becomes blue under the same conditions. A very convenient method is to immerse strips of filter paper in the solution and allow them to dry. One of these can then be dipped into the solution to be tested.

These tests are so practical and so easy of application that they are worth remembering. Both of them are very delicate. The objection urged against them is that certain other substances, as lactic acid in a concentration not usually found even in a diseased stomach, will produce the same color change. Nevertheless, the failure of the change to take place is an undoubted proof that no free hydrochloric acid is present. What I have said is true only in a restricted sense. It is quite certain that careful chemical tests made by an expert chemist may show the presence of acid where these color tests fail. This I know from personal experience. Acid has been found in the chemical laboratory of the University in cases in which I failed to discover it with the color tests. For clinical purposes, however, I believe these tests to be efficient. The reaction for lactic acid—known as Uffelmann's test—is applied as follows: Dissolve a small amount of chloride of iron in a little water in a test tube, and add a few drops of a strong solution of carbolic acid until a purple color is produced. If, now, to this be added some of the filtered contents the purple color will become a canary yellow if lactic acid be present.

This second case is also one of gastric disorder, and is one of extreme interest. He has been kindly brought here by the physician under whose care he is. Unfortunately we have but little time remaining in which to study it together. The paient is a man of 43 years of age. His father and one sister died of phthisis. He has never drank to excess. Except for chronic constipation he was always well and strong until two and a half years ago, when he found that he was losing appetite. This was soon followed by discomfort after eating, with frequent vomiting occurring an hour or an hour and a half after meals, and an increase in constipation. One and a half years ago he had a great deal of vomiting. He has been somewhat pale ever since he came to this country, 24 years ago, and thinks he has been as pale as at present for the last two years. His best weight has been 145 pounds, and his average weight 136 pounds. His present weight is 119 pounds. Last December he had to give up work on account of increasing weakness. The dyspeptic symptoms at that time became more marked, except the vomiting, which has been less. He has had ringing in the ears, accompanied by a sensation of lightness in the head.

When examined a year ago the skin had a pale, light-yellow tint, with but little subcutaneous fat. There was marked pulsation in the vessels of the neck, a soft and somewhat accelerated pulse, and a blowing murmur at the apex of the heart with a sharp second sound. The hepatic and splenic dullness did not seem to be increased. No tumor could be found in the abdomen, even by the most careful examination. The examination of the blood showed 681,000 red blood cells to the cubic millimetre, with a slight increase of the white cells. Five grains of salol were given and the urine tested after a half hour and after one and a half hours, but no salicylic acid was found. This seemed to indicate a possible motor insufficiency of the stomach. Œdema of the feet and ankles was first noticed last June. The urine, however, does not show any evidence of Bright's disease. He improved somewhat through the summer, and the blood-count made last December showed 2,000,000 erythrocytes, *i. e.*, 40 per cent., with a percentage of hæmoglobin of 50. Thus, as you see, the percentage of hæmoglobin exceeded considerably that of erythrocytes; a condition

characteristic of pernicious anæmia. In January there was great weakness and much nausea and retching with pain. Lavage brought up a quantity of foul-smelling mucus. At no time has hydrochloric acid been found in the gastric contents. His condition has certainly been getting worse, for some time past. I have been able to read you only scattered extracts from the elaborate clinical history which his physician has made.

Turning to the patient you notice at once the excessive pallor, yet without any decided emaciation. The pallor has the peculiar faint lemon tint often attending extreme anæmia. There has been no growth found in the abdomen. Moreover, if this were a case of cancer we should probably have had a fatal issue long before this.

On percussion you notice that the loud gastric tympany is very extensive, and his physician has determined, by giving him water and then examining in the way I have described, that the lower border of the stomach extends below the umbilicus. We undoubtedly have here a dilatation of the stomach without any constriction at the pylorous to account for it. Here is a case in which there has been no hydrochloric acid found, yet in which there is no reason to believe in the existence of cancer.

I have shown you this case because it is a very possible example of a rare condition, or at least of one very little understood. It is probably an example of atrophy of the gastric mucous membrane. I have seen only one instance of this disease, and that post mortem, and there are not many cases reported. In this disease you find a combination to some extent of the symptoms of chronic gastritis with those of pernicious anæmia. According to George Meyer, who has seen several cases and carefully studied the subject, the symptoms are dilatation of the stomach, disappearance of the natural secretion, cardialgia and diminution of the gastric movements, while at the same time there is extreme anæmia with fairly good general condition and an absence of marked emaciation. In these cases the microscope shows that the gastric tubules have almost entirely disappeared. There is practically no mucous membrane. You will find a small-celled infiltration with cysts where the membrane should be, with scanty remains of glands here and there. The other layers of the stomach-wall are not much affected, except that the submucosa is thickened. In certain cases an overgrowth of connective tissue occurs instead of the infiltration and chokes the glands, as it were.

Fenwick, Nothnagel, Osler and Henry, Litton, Ewald, Kinnicutt and a few others have reported cases of this affection, with pretty much the same symptoms. The disease is rare—or rather the reported cases are—and the number of instances of it might almost be counted on the fingers of the two hands. The diagnosis is often impossible, ante-mortem and in the case before us, as in all others, can only be made provisionally. Yet I think, with the symptoms exhibited by this man, we are justified in considering this as very probably a genuine instance of atrophy of the gastric mucous membrane. Review with me once more what may be gathered from the man's history and appearance. The extreme pallor and the lack of marked emaciation are characteristic of pernicious anæmia. The condition of the blood is also characteristic of this disease. Then he has marked dyspeptic symptoms with a failure of the secretion of hydrochloric acid. There is evidence of motor insufficiency of the stomach, and there is gastrectasia. This combination of symptoms exactly fills the requirements necessary to justify the diagnosis.

Atrophy of the gastric tubules may produce dilatation, and conversely dilatation may be followed by atrophy. In the latter case the tension and pressure on the gastric wall induces the atrophy. In the former the food, not being properly digested, lies in the stomach, decomposes with the formation of gases, and produces dilatation. This patient at times does not vomit for several days and then fills a large basin with the contents of his stomach.

The treatment of this case is practically what has been already employed; though, in fact, very little can be done in the way of therapy. Arsenic has been given him in the hope that it might act as an alterative. He has also had gastro-intestinal antiseptics, such as naphthalin, aromatics, salol and the like. Bismuth has been tried, as has nitrate of silver, in an effort to control the vomiting. Some dependence can be placed on the administration of predigested foods, in the hope that in this way the lack of digestive power may be supplemented.

Lavage at frequent intervals is certainly indicated, and has been repeatedly tried in his case. Unfortunately, though it gives decided relief, it exhausts him to such an extent that it cannot be employed.

It is said that people living out-of-door lives are hypermetropic.

COMMUNICATIONS.

TRAUMATISM OF THE CHEST.[1]

BY J. McFADDEN GASTON, M. D.,

ATLANTA, GA.

In the course of my investigations on thoracic surgery for The Annual of the Universal Medical Sciences, I have been strongly impressed with the lack of knowledge in regard to the injuries of the chest. While this subject has been considered somewhat carefully in my two contributions to that work, there are many practical details of great importance, which are not touched upon, owing to the paucity of data afforded by the very limited reports in this branch of surgical experience.

It is not my purpose now to enter into the minute distinctions of the lesions resulting from violence to the walls and contained viscera of the chest. I ask for the attention of surgeons to the great advantage of methodic treatment of traumatism of the chest.

All those inflammatory processes of a latent or idiopathic nature, which lead to serious effusions primarily, or to suppuration secondarily, within the thoracic cavity, are excluded, as not germain to our present undertaking. In like manner, the very extensive lesions involved in operations for the relief of the above conditions in all stages, do not come within the scope of this paper.

Foreign bodies entering through the trachea, into the bronchi and causing mechanical obstruction, or inflammatory complications, call for consideration, under the general inflammatory impression transmitted to the pulmonary structure.

Blows upon the parietes of the thorax which propagate a shock to the lungs or heart, involving an impairment of functions, or subsequent organic changes, come appropriately under the heading of traumatism, though no superficial contused wound is apparent.

Of course, all violence from without which produces injury to the structures within the chest, should be regarded as the proximate cause of the lesion, whether it be hæmorrhage, congestion or inflammation.

The grosser accompaniments or consequences of violence, consisting in notable contusion of the soft parts and fracture of the bony walls of the chest, are frequently the exciting causes of transmitted inflammation to the vital structures of the thorax.

Among the gravest injuries to the chest are the wounds by firearms and by cutting or puncturing instruments. These generally bring about the entrance of air into the pleural cavity and thus by pressure upon the corresponding lung there is serious interference with the respiratory act. Should the pulmonary tissue be involved in the wound, there is likely to occur emphysema, from the entrance of air into the areolar tissue of its parenchymatous structure, so as to effectually prevent the alternate expansion and contraction of the bronchial ramifications.

The former condition of pneumothorax may be a result of air escaping from the bronchial tubes when wounded, even when the external incision or puncture may be of a valvular nature, which does not admit of the entrance of air from without.

If the external wound is patulous, the ingress and egress of air occurs with each act of expiration and inspiration, inducing the condition of traumatopnœa. This is a most unpleasant result, and introduces a grave complication in the nature of the case.

There is also, most frequently, sanguineous extravasation into the pleural cavity, from such injuries, and if the lung has not become collapsed from the entrance of air, its function of respiration is impeded, if not obliterated, by the blood pressure.

Should the parenchymatous structure be involved in gunshot or punctured wounds of the lungs, there may be emphysema to a greater or less extent, throughout the cellular tissue of the thorax and adjacent parts.

The constitutional or systemic effects of any violence to the thorax depends upon the amount of shock in the first instance or the inflammatory process which is developed subsequently.

The greatest diligence on the part of the surgeon is requisite to avert the immediate fatal result of penetrating chest wounds. Apart from the general manifestations of chest wounds there are local effects from mechanical causes, which require our consideration.

One of the most serious consequences of violence to the walls of the thorax is rupture of the lungs. A fall upon some solid body or the pressure of some heavy weight, while the lungs are greatly distended by closure of the glottis, induces rupture of the pulmonary tissue, with all the serious results of pneumothorax and hæmoptisis. This may occur even without an abrasion upon the surface of the chest; and the history of such

[1] Read before the Surgical Section of the American Medical Association, at the meeting in Washington, D. C., May 6th, 1891.

an accident is the only explanation of the grave condition within the thorax. A forcible impression upon the walls of the chest may fracture the sternum or ribs and drive either inward so as to lacerate the lungs or the heart, leading to immediate or remote serious effects.

One of the grave consequences of an opening through the chest wall is the protrusion of a portion of the lung, constituting a hernia. If this should occur under the observation of a surgeon, he would find little difficulty in returning it and retaining it within by a compress. But most frequently it has been exposed for some hours and has become engorged, so that it is entirely impracticable to reduce it without enlarging the opening in the walls of the chest. This would seem the most feasible mode of relief, if the vitality of the tissue had not been impaired by the constriction. But it is generally held to be safest, either to allow the protrusion to remain and slough away or to assist its detachment by placing an elastic ligature around the neck of the hernial tumor. The edges thus become agglutinated and the lung is occluded. Then may also occur laceration of the lesser or greater blood vessels of the thorax calling for prompt relief, if the injury does not prove immediately fatal.

It has been proven by subsequent observation of the effects, that lesions of the heart have healed and that injury to the coats of the large arteries are not necessarily fatal. But there is no instance on record of a wound of the vena cava without a fatal result. The thoracic duct, in like manner, cannot be wounded with impunity, and the escape of the lymph terminates in death.

While the ligation of the intercostal arteries, the internal mammary and the subclavian is attended with difficulty, the hæmorrhage from them rarely may be controlled, and the patient should not be abandoned to his fate. If blood has accumulated within, it may be withdrawn by suction or its escape may be prevented by position.

Those who have had the largest sphere of observation in this branch of thoracic surgery, will best understand the uncertainty hanging over pulmonary disorders resulting from violence. Commencing with the doubts as to the production of traumatic pneumonia, and running through the abscesses of the parenchymatous structure of the lungs, it is remarkable how little is finally and definitely determined as a guide for practice in thoracic injuries.

It will be found, upon attempting to analyze the reports of such lesions, that quite a variety of opinions are entertained by different observers, and that really no methodic treatment has been adopted generally by the medical profession. I know of no work on surgery which lays down any fixed rule for the practitioner in the management of wounds of the chest.

The contributions to the literature of traumatism of the chest in Holmes's System of Surgery, Vol. I, in The International Encyclopædia of Surgery, Vol. II, in The Reference Hand-book of Medical Sciences, Vol. IV, and in The Annual of the Universal Medical Sciences for the years 1889–90–91, represent fairly the status of this branch of surgery. Those who seek to keep abreast of the recognized data, may learn from these works what has been accomplished for the relief of this class of injuries. It will be noted that there are conflicting views in regard to the proper treatment of some of the consequences of penetrating wounds of the chest, dependent, no doubt, to a great extent, upon the different stand-points from which observations are made. While there is a correspondence, for the most part, among different authorities, in the propriety of closing the external opening in the wall of the chest, when the amount of blood in the pleural cavity is small, contradicting opinions are expressed when it is large.

To define more clearly the attitude of those who have written upon this topic, I may state that individual views of the nature of such injuries, with the steps recommended for their relief, rest very much upon personal observation and not upon the consensus of general experiences by the profession.

There are articles upon thoracic wounds in most of our standard works on surgery, presenting many points of a practical bearing, as viewed by the author. Yet, with such material differences in their application, under the emergency of treatment, as to avail little for the practitioner.

While we should not overlook the writings of former days, it may be stated that little progress has been made in the elucidation of wounds of the chest since the work of Gross and Agnew were presented, and some of the more recent authors, as Wyeth and Roberts, have touched upon chest injuries very briefly. While Senn ignores, with few exceptions, traumatic developments of the thorax, many important data, illustrating the results of gunshot wounds of the chest are given in The Surgical History of the War, published by the U. S. Government, and

the statistics of non-penetrating and penetrating wounds of the chest, therein presented, demonstrates the gravity of the latter as compared with the former in a most conclusive manner. This, however, only confirms the results of the records of military operations throughout the world, showing that about 1 per cent. of non-penetrating wounds of the chest prove fatal, while over 65 per cent. of penetrating wounds terminate in death at an early period after the injury.

One of the practical questions of greatest moment in regard to the hermetical sealing of gunshot wounds of the thorax, remains unsettled.

Experiments upon the inferior animals, commencing with those of Houston in 1728, for illustrating the effects of punctures and incisions into the thoracic cavity, have been attended with such different results upon the lungs, that it is yet undetermined whether collapses ensue directly from these wounds. There is such an intimate relation of the surface of the lungs to the costal pleura, that something must separate them for the occurrence of pneumo-thorax, and hence it occurs that openings are not always followed by this result.

It is held that the falling away of the lung is not a uniform consequence of a penetrating wound of the chest. If the wound is small, or if it is at a distance from the free margin of either lobe, the expanded lung remains in contact with the costal pleura.

The adhesion of the two pleural surfaces is illustrated by an experiment of Surgeon A. H. Smith, in which, in a recently killed animal, an opening was made in an intercostal space, midway between the sternum and the spine. The lung did not collapse, but on making another in the same intercostal space close to the sternum, the outer surface of the lung was observed to slide backwards, though still remaining in contact with the chest walls, until the edge of the lobe came opposite the first opening. Then for the first time the air entered here, and the pneumothorax became complete.

Gordon and McDonald found that with small tubes introduced into the chest, the breathing became quick and laborious, while the lungs had fallen away from the chest walls for an inch. After four minutes, they enlarged the wounds and put in tubes, whose united calibre was twice that of the glottis. The respiration then became very laborious. On closing the wounds, however, and applying friction to the chest, the respiration was restored and in ten minutes the animal was able to walk about. It was killed on the 5th day and nothing notable way found in the chest.

Dr. Northrup reports some experiments on animals, contradicting the statements of Samuel West, that the force of cohesion sufficed to maintain the lung in complete expansion when the parietal pleura was punctured. Further experiments were made in which a dog's two pluræ were fitted with double-flanged canulæ, stoppered with corks. Until the dog recovered from ether the two corks were left in place. When fully recovered one cork was withdrawn, and the dog scarcely suffered dyspnœa on moderate exercise. When both corks were removed the dog tumbled about for two minutes and succumbed to some dyspnœa, which again entirely disappeared on replacing the corks.

These results throw some light upon the practical resort to closure of the external openings into the pleural cavity as a curative measure in cases of penetrating wounds of the chest.

Howard's proposition to the Surgeon General of the U. S., during the war, to test the process of hermitically sealing the external orifices of gun-shot wounds of the chest, met with so much prejudice on the part of the surgeons of the Federal army, that it was used in a limited number of cases. It is also inferred that the conditions under which this measure was tried, were not favorable to its success, as the most grave cases were the subjects. Judging from my own experience of the good effects of closing penetrating wounds of the chest, and from the records of cases thus treated by others, it seems unfortunate that hermetical sealing was not applied on a larger scale, so as to afford the statistics for a final and conclusive decision as to its merits. Independent of the recognized advantages of closure in the lesser accumulations of blood in the pleural cavity, it is held by some, with a show of practical discernment, that in the most extreme cases of thoracic hæmorrhages, the flow of blood externally should be arrested by plugging the orifice, so as to favor the coagulation of the blood within, and by compression upon the lung to prevent further extravasation.

If this course is applicable in the most aggravated condition of penetrating wounds of the chest, as well as to the simpler form in which there is a slight hæmorrhage into the pleural cavity, why may it not prove serviceable in the intermediate accumulations

of blood in the thorax, and thus be applicable to every variety of penetrating wounds of the chest?

It is not expected that a general rule can be laid down, without exceptions, for the immediate and complete closure of all penetrating wounds of the chest. There must be certain preliminaries observed in the preparation of the patient for receiving the benefits of such procedure, so as to close the orifice with the least blood in the cavity of the pleura, that is possible. Placing the patient so that the opening shall be the most dependent part, with a firm bandage around the thorax, and making the occlusion immediately after the expulsion of air and blood from the wound, by forcible inspiration, should promote a favorable result.

If the case is complicated with emphysema, involving any considerable portion of the surface, plugging the orifice with a condom stuffed with sponges, as has been suggested for the arrest of hæmorrhage from an intercostal artery, will prove efficient in preventing the escape of air into the cellular tissues, and at the same time accomplish complete occlusion of the thoracic cavity.

A comparison of this procedure may be made with that in which the air enters the cavity of the pleura and induces collapse of the lung, thus arresting the flow of blood from the wounded darenchyma, with a tube in the opening, as recommended by Packard, for prevention of emphysema. In this latter, the air pressure is supposed to arrest the bleeding. In the other condition, blood clot presses upon the lung so as to control the hæmorrhage.

The variable influence of the air in the pleura, with more or less air entering the lung by the inspiratory act of the sound side, renders this recourse very doubtful in permanently controlling the escape of blood from a wound of the lung.

On the contrary, the formation of blood-clot within the pleura keeps up a pressure which can be relied on to prevent the further bleeding from the pulmonary lesion. All those who have observed the relief of distressing dyspnœa, by closing an open wound of the chest, concur in its great benefits.

It may be inferred from the favorable progress of cases in which a large accumulation of blood has remained in the pleural cavity, that its gradual absorption occurs. If the air is completely shut off from without, of course, germs cannot enter to set up decomposition in the mass, even should there be a perforation of the bronchia; as it is held that air passing through this sieve-like structure is rendered innocuous.

With the larger death rate from penetrating wounds of the chest, treated without special reference to the process of occlusion, the result is not likely to be more serious from a uniform adoption of sealing hermetically all external openings of penetrating wounds of the thorax. If the worst consequence of this procedure ensues in purulent development, there is open to the surgeons such measures of relief as have been adopted successfully in emphysema from other inflammatory processes.

In this connection, a few cases which have come under my observation, may serve to illustrate the open and closed methods of treating wounds involving the thoracic cavity. Many instances of gun-shot wounds of the chest were brought to my attention as Chief Surgeon of Division during the civil war in this country. But I had no opportunity of following up the subsequent course of these injuries; and would refer to reports of such cases in The Surgical History of the War for the results. I will give, however, an outline of some characteristic cases, occurring in my own private practice and in consultation with others, during the past few years.

One case had a pistol-ball wound at short range between the fourth and fifth ribs, on the right side, in front, and ranging downward. All the physical signs were present, indicating a wound of the right lung, with extravasation of blood into the pleural cavity. It was kept open for a time but closed afterwards spontaneously and terminated fatally.

Another case, in which a ball from a large Colt's revolver, traversed the left side of the chest, entering through the lower border of the pectoral muscle and escaping between the ninth and tenth ribs near their cartilages, instead the pleural cavity. There was a discharge of frothy blood from the posterior wound and the physical signs of extensive sanguinary extravasations into the left pleural cavity.

The heart was perceptibly pressed over to the right, carrying the apex beyond the median line. While no suture was used to close the wounds, they were hermetically sealed by antiseptic dressings; and, notwithstanding considerable constitutional disturbance subsequently, the patient made a good recovery.

A third case was a child, accidentally shot, the pistol ball entering through the ensiform cartilage and ranging upwards,

no precaution was used to close the wound, and the patient died from emphysema.

The fourth case was from a pistol shot which entered just below the ensiform cartilage ranging upwards to the right and lodging above the eighth rib, thus passing through the diaphragm and lower portion of the right pleural cavity. The external hæmorrhage was not pronounced, but the presence of blood in the chest was inferred from the physical signs of dullness upon percussion and diminution of the respiratory murmur under auscultation.

There seemed to be no indication for occlusion of the external wound and it was therefore left open. As there may have existed complications involving the abdominal viscera, the fatal termination on the fourth day cannot throw any light upon the true cause of death.

The fifth case affords an instance of a pistol ball entering the chest, immediately over the heart,traversing the mediastinum and lodging upon the sixth rib of the right side, just behind the posterior axillary line.

The external wound was occluded, and the ball was not removed until after the general shock and slight inflammatory reaction had passed off. The patient made a good recovery by the strict observance of masterly inactivity.

This case, with that preceding, having the ball lodged superficially for several days before removal, seem to emphasize the caution against cutting down and extracting a ball under such circumstances, at the outset.

Time should be allowed for adhesive inflammation to block up the communication with the cavity, as otherwise a direct counter opening into the chest must result.

I recall, in this connection, after the first Manassas battle, allowing a minnie ball, which was impacted in the clavicle and first rib, to remain, but by its extraction the chest cavity should be exposed; but the final result of the case is not known.

The practice of removing balls lodged between ribs, which is inculcated in Agnew's Surgery, without proper limitation, is more honored in the breach than by the observance. It is evident that the immediate extraction of a ball from the border of a rib, after it has traversed the chest, must leave an opening into the cavity of the pleura and aggravate the gravity of the case.

A counter opening in muscular structures for the removal of a ball which is near the surface, does not in the experience of surgeons of large practices, retard the healing process along the line traversed by the ball. But with the conditions presented in a gunshot wound of the thorax, when an opening already has been made by the entrance of the ball it is not good surgery to make another for the extraction, until the wall behind has become solidified.

In illustration of the effects of punctured and incised wounds of the chest, a few examples of knife-stabs, which have occurred in my practice will be added.

A case of stabbing, between the fourth and fifth ribs, in front of the anterior axillary line on the left side was accompanied with localized emphysema. While there was evidence of sanguineous effusions in the pleural cavity the bleeding was profuse externally.

There was a slight dyspnœa upon lying down which was relieved in the sitting posture. The wound was closed by adhesive plaster with a compress and bandage and the patient recovered without untoward symptoms.

It has not been found necessary to use stitches in these wounds inflicted by the thrust of a knife blade, as the coaptation is effected by the above process, so as to hermetically close the opening in the chest. In another case a stab was inflicted between the sixth and seventh ribs over the left side near margin of the scapula, from which blood and air escaped at each inspiration, with considerable accumulation of blood in the pleura, and hæmoptysis.

The external wound was closed immediately after a gush of blood and air from the opening. The patient became more quiet afterwards. This case was accompanied with traumatic pneumonia and marked constitutional disturbance, but ultimately recovered.

A third case came under my observation in which a knife blade entered between the fifth and sixth ribs on the right side, penetrating the lungs and attended with the accumulation of blood in the pleural cavity. There was no very marked dyspnœa, and as the flow of blood externally, gradually diminished with the dependent position of the wound, it was not thought that closure of the opening was indicated.

Inflammatory symptoms soon developed, with subsequent adhesion of the pulmonary and parietal pleura. In the end suppuration of the lung found its way through the external opening. A weak solution of carbolic acid was daily, injected into the suppurating tract, and the healing process progressed favorably, so that there remained,

eventually, but slight impairment of the lung from the injury.

The inference from these cases goes to prove that suppuration is more likely to occur when the incised wound is left open than when it is closed immediately and kept occluded.

A fourth case was seen some days after a stab had been inflicted between the seventh and eighth ribs, and there was a protusion of a small globular mass of pulmonary tissues from the wound. As it had occurred shortly after the injury and was tightly constricted by the margins of the wound in the thoracic wall, the neck of the hernial tumor was encircled with an elastic ligature, as most likely to effect a prompt and safe detachment of the mass. In a few days it separated, and there was no further trouble with the case. If there was any escape of blood into the pleura it was most effectually shut in by the plugging of the opening, and afforded an illustration of the favorable issue of hermetical sealing in penetrating wounds of the thoracic walls.

A RÉSUMÉ OF THE HISTORY AND PRACTICAL APPLICATION OF HYDROGEN PEROXIDE IN SURGICAL AFFECTIONS.

BY S. POTTS EAGLETON, M.D.

RESIDENT PHYSICIAN IN THE CHILDREN'S HOSPITAL, PHILADELPHIA.

Hydrogen peroxide was discovered by M. Thenard, a French chemist, in the year 1818. Since which time it has, like many other therapeutical remedies, laid dormant, occasionally being brought forward by some "enthusiast" and its virtues highly extolled for a time. But the drug, unequal to the task of proving all that had been said in its favor, was again and again returned to its stall of oblivion. Within the past few years, it has been introduced to the notice of the medical profession, on account of its antiseptic properties, and apparently has awakened into active therapeutic life.

Most of the preparations or hydrogen peroxide in the market to-day, according to C. T. Kingzett,[1] are made by the process which originated with its discoverer. Physically it is like water, transparent, colorless, odorless, and generally tasteless; occasionally, however, a slight metallic taste may be noticed. The specific gravity varies, generally it is about 1,450. It remains liquid at zero. Chemically, it is one molecule of water in feeble combination with an atom of oxygen, (H_2 0+0—H_2 0_2). That this extra amount of oxygen does not show a strong affinity for the water,with which it enters into combination, is made evident by the rapid decomposition of the compound into its original constituents (water and oxygen) when brought into contact with any surface containing pus. It is this factor of being readily decomposed and setting free nascent oxygen which renders it of practical utility in the treatment of disease.

In looking over the literature of the subject, I find that Dr. B. W. Richardson,[1] in 1862, called attention to the action of hydrogen peroxide in an able article upon the subject, which excited wide-spread interest in the profession at that time and has led to many experiments with the drug, both in surgery and medicine.

It is my purpose to confine myself in its study, entirely to the treatment of surgical affections. Before referring to the results of my own experience, during the last few months, I will briefly allude to some of the most important monographs which have appeared from time to time in our medical journals. C. T. Kingzett[2] believes that the substance exhibits striking antiseptic effects and is capable, even in very small quantities, of arresting the so-called process of fermentation which is originated by living organisms. He further calls attention to the fact that care should be exercised in making the solution neutral before using the same, and yet admits that neutral solutions are by no means as staple as are those of a slightly acid reaction. In closing his monograph he states that the expectations that the compound would prove of peculiar benefit in the treatment of wounds have been amply realized in the practice of several noted surgeons of France, among whom may be mentioned M. Baldy, M. M. Reynard and M. Reau. In summing up his article he further says that, in his opinion, hydrogen peroxide is far superior to phenol, and that it has been demonstrated beyond question that all wounds treated with peroxide of hydrogen have progressed well, healing generally by first intention.

A. E. Prince,[3] speaks most favorably of

the results obtained with this remedy.

It is as a local therapeutic agent that it has asserted its supremacy and secured the attention of medical pioneers in all departments of medicine. Believing, as he does, that in comparison with iodoform it is inferior as an antiseptic, but, like the latter, it produces little or no irritation, when used about tender organs. C. E. Shelly[1] considers it to possess anæsthetic properties, and at the same time claiming for the drug, not only a pus-destroyer, but that it is an actual stimulant to the surface of wounds. To the carefully conducted experiments of Dr. P. Miguet, quoted by W. D. Bizett,[2] we owe the establishment, on a firm basis, of hydrogen peroxide as a positive germicide. The line of experimentation pursued had the following aim: to determine the quantity of various substances, commonly used as germicides, which, added to a quart of beef tea, would prevent decomposition. Miguet found among a long list of substances used by him, that only two were more powerful than hydrogen peroxide. The following table shows the relative strength, according to his experiments, of the four most powerful germicides:

Biniodide Mercury	0.025 grains
Biniodide Silver	0.03 grains.
Hydrogen Peroxide	0.05 grains.
Bichloride Mercury	0.07 grains.

The results thus obtained, place hydrogen peroxide in the lead of bichloride mercury as a germicide, with the advantage, also, of being absolutely void of any toxic action, while the corrosive sublimate is a most virulent poison. Bizett[3] claims that when the pure peroxide, which is syrupy in consistence, is brought into contact with living tissues, it acts as a direct caustic. Various experiments were made by H. Gifford[4] directly with the *disease germs*, thus testing the germicidal action of the peroxide. Two methods of determining its ability to destroy germs, were used, that of Koch and his own well-known method. The preparation of peroxide used, was that of Chas. Marchand's (15 vol.). Gifford found that the white and yellow cocci, as well as the bacilli anthrax, were killed in exposures of from ¾ to 1½ minutes. It required but ¾ minute to destroy fully developed anthrax spores. He further found that the solution exposed for 40 days, to a temperature of 68–75° killed the yellow pus cocci in from 10–11 minutes. The same solution of peroxide, when diluted with *four* times its bulk, requires an exposure of 30 minutes to kill the pus cocci. If diluted with an equal volume, it kills within ¾ minute. After an experience of six months, J. N. Love[1] sums up the action of hydrogen peroxide as follows: It is a most efficient means of cleansing purulent surfaces, deep cavities, and sinuses, stimulating the healthy process in ulcerating parts. As a destroyer of microbes, a cleanser and securer of comfort, it is of great value as a local application.

My own experience with this drug in surgical affections, during the past ten months, has been most satisfactory. During that time I have used the remedy in the following affections: Abscesses (acute and chronic, of various kinds), suppurating glands, sloughing gangrenous wounds, empyema of the chest, necrosis (general and localized), suppurative otitis media, and wounds of all descriptions. The ages of the cases treated, varied from two to thirteen years. The mode of applying the peroxide was as follows: All cavities, crevices, etc., were syringed with the bichloride of mercury (1–2000, to 1–6000) and then carefully cleansed with the hydrogen peroxide (Marchand's).

At first one volume of this solution was diluted with two to three times its bulk. Later on, I used the full strength. The first effect noticed after applying the peroxide, was the rapid oxidation of all purulent or bloody material, which would cause the distention of crevices, no matter how minute with the oxygen, which was eliminated as a frothy (often yellowish, depending upon the quantity of pus present) bubbling substance. After the oxidation was completed, the wound was always left in a clean, sweet condition, absolutely free from pus. The wounds were then gently dusted over with iodoform and the usual antiseptic dressings of gauze, etc., were applied. On removal of the dressings, a few days later, it was noticed that the wounds were in almost every instance cleaner (especially marked in acute cases), more healthy in appearance and with a decided diminution in the quantity of pus secreted. The thought being suggested, that possibly the bichloride and not the peroxide was instrumental in producing the favorable results noticed, I commenced a series of control experiments. I would, at one dress-

ing, use simply the bichloride of mercury, following this, at the next dressing, with the peroxide. Thus making actual comparisons in the same cases. After several alternate dressings as above, I found *without exception* that the hydrogen peroxide perceptably diminished pus formation to a much greater degree than simply the bichloride alone.

The belief that iodoform should not be used in conjunction with the peroxide, for fear of liberating free iodine, which, as a direct irritant, would defeat the object in view, is, I believe, erroneous. I found that when a quantity of iodoform was placed in a small receptacle covered with the peroxide solution and then set aside for periods varying from three hours to three days, on being treated chemically for free iodine, with the ordinary starch test, gave negative results. Although one drop of a solution of iodine, on being added to the same solutions, gave a brilliant reaction on addition of the starch.

In all cases in which the peroxide was given a fair trial, I have observed a direct healing effect upon the granulating tissues. It is therefore evident that owing to its oxidizing action on the pus and the diminution of the purulent secretions after its use, it does, either directly or indirectly, cause a destructiou of the anthrax bacillus. In concluding my article, I think from the clinical as well as the experimental evidence which has been deduced, we can safely sum up the action of peroxide of hydrogen in the treatment of surgical affections, as follows:

1. Hydrogen peroxide is a positive germicide and a possible stimulant to granulating tissues.

2. Owing to its especial property of eliminating oxygen, it is of unparalleled value in the distention of suppurating sinuses and cavities, especially in the mastoid region or where it is almost impossible to reach unhealthy surfaces by other means.

3. The diluted solution is perfectly harmless and can with safety be used in any quantity.

4. The strong concentrated solution, syrupy in consistence, is a direct irritant to all tissues and should never be used.

5. It possesses healing and cleansing qualities as well as those germicidal in nature.

6. When exposed to light it loses strength; care should therefore be exercised in keeping the bottles well stopped with rubber corks, and in a cool, dry place.

7. Fibrin, cellular tissue and some metals, instantly decompose it. In contact with sugar and starch it eliminates carbon dioxide (CO_2). Albumen, gelatine, urea and cutaneous tissues have no affect upon it, while ammonia, aconite, tobacco and hydrocyanic acid increase its stability.

8. In washing suppurating surfaces, it should be used until oxidation ceases, thus showing a complete destruction of all existing purulent material.[1]

TETANY.[2]

BY E. H. SMALL, M. D.,
PITTSBURGH.

On November 29th, 1890, I was called to see M. B., a fat, healthy-looking, breast-fed baby boy, aged 11 months. His hands and feet were much swollen, œdematous, and of a cyanotic tinge. His mother said that they had been "spotted," *i. e.*, ecchymotic, before I had come. The fingers were strongly flexed at the metacarpal phalangeal joints, while the phalangeal joints were as strongly extended. The thumbs were adducted and flexed. The feet were extended at the ankles as in talipes equinus, while the toes were strongly flexed. Attempts to straighten out these contractions caused great pain. The mother said that at first the child cried a good deal and that his hands and feet were tender and painful. So much were the hands and feet, particularly the dorsal surface, swollen, that I suspected nephritis. The urine, however, contained no albumen. The child had always been strong and healthy, having had no other sickness.

Two days before, Thanksgiving, the child had been given some turkey and cranberries to eat, which had caused indigestion. When I called he had had no satisfactory movement of the bowels for some time. I gave him two one-half grain doses of calomel one hour apart, and twenty drops of the elixir of bromide of potassium four times daily, and told the mother to rub his hands and feet with alcohol and water. The next day he was much better. I directed hot fomentations to be applied to the hands and feet instead of the rubbing with alcohol and water. In a week the child was about as well as usual.

[1] Read before the D. Hayes Agnew Surgical Society of the undergraduates of the Medical Department of the University of Pa., February, 1891.

[2] Read before the Allegheny County Medical Society, March 17, 1891.

Four weeks before his gums had been scored by another doctor. A few days before my visit, the two first teeth had appeared, *i. e.*, at eleven months. The anterior fontanel was larger than normal for his age, and the costo-chondral articulations were rather more prominent than normal. He has an older brother and sister who are perfectly healthy.

When I first saw this case, I thought it to be one of tetany, and its course and termination have proved it to have been such. I had never before seen this disease in a child, but had seen one case in Vienna in a pregnant woman.

Although this disease has doubtless always existed, and although it was described as far back as 1831 by a Frenchman, M. Dance, as occurring in an adult, and in 1832 by another Frenchman, M. Tonnele, as a new convulsive disease of childhood, yet it is but seldom mentioned in the more common medical text-books. The name tetany was first given it by Dr. Corvisart, in 1851. Dunglison's Dictionary, 1874, speaks of "Tetanilla" diminutive of tetanus, saying that this disease is also called tetany.

Dr. Smith, of New York, defines it as "a disease in which there is a tonic contraction of the muscles, commonly those of the extremities, but sometimes also those of the face or trunk, produced by causes external to the nervous system, and usually of temporary duration." This definition shuts out true muscular contractions arising from disease of the brain or spinal cord, in which the contractions are both but a symptom, and not the disease itself. Henoch describes it under the name of "Idiopathischen contracturen" and regards it as a kind of abortive form of convulsions. Dr. Cherdle, of London, says, "Laryngismus, tetany and general convulsions are the positive, comparative and superlative of the convulsive state in childhood."

Causes: Cases are recorded between the ages of six months and sixty-one years. Most cases occur in infancy and childhood; more in males than in females. The most common cause seems to be disorders of the digestive system, as diarrhœa, habitual constipation, worms, and dentition. Charles Warrington Earle, of Chicago, gives a case of a healthy girl two and one-half years old, in whom tetany occurred on the day after she had eaten heartily of fried potatoes. Perhaps my case was caused by the turkey and cranberry sauce of Thanksgiving, two days before.

It may arise in persons who are in poor health from other diseases, as pneumonia, bronchitis, cholera, typhoid fever and dysentery. Exposure to wet and cold has seemed to cause it. Hence, some think it a rheumatic affection. Erb says: "Many physicians have regarded it as an exquisite example of rheumatic disease." In adults, commencing puberty, pregnancy, as in the case I saw in Vienna, and nursing, may cause it. Rhachitis is also regarded as a cause, which may hold in my case, on account of the delayed dentition, large size of fontanel and enlarged articulations.

Symptoms: In patients old enough to describe their symptoms, tetany begins with pain in the head and an uneasy, tingling, burning sensation in the limbs. In children, the objective symptoms are those first noticed. The peculiar shape of the hands and feet, their rigidity, and pain on pressure are the commonest symptoms. Generally the fingers and toes are flexed on the palms and soles, occasionally extended. At times the joints of the hands and feet are also affected, or the elbow-joint—so that the fore-arm appears flexed upon the humerus, the hands upon the fore-arm, and the foot upwards, or else toward the sole. The thighs may be adducted, or flexed, the legs extended or flexed, and the feet extended as in talipes equinus. The contractions are always bilateral and symmetrical. Attempts to straighten out the contractions cause pain. Œdema, with a cyanotic tinge of the back of the hands and feet and occasionally ecchymoses, produced according to Henoch, by the pressure of the contracting muscles on the intermuscular veins, is oft-times present. In severe cases the muscles of the trunk and head may be affected, but this is rare in children. Trousseau's sign—compression of the artery and nerve supplying the contracted muscles increasing the contractions—can be sometimes observed. The electrical excitability of the nerve supplying the affected muscles is increased, as is also the patellar reflex.

Diagnosis: This may be made out by the peculiar grouping of the symptoms, the characteristic position of the extremities, and the absence of cerebral and general disturbances. Tetanus neonatorum and organic disease of the brain and spinal cord are the principal diseases with which it may be confounded. Tetanus generally occurs within a few days after birth, almost never after the first month; tetany is very rare under the age of one month. In tetanus the muscles of mastication are early affected; in tetany the con-

tractions begin in the extremities, and the muscles of mastication are never, or only in the last stages, affected. In tetanus the symptoms tend rapidly to become worse and worse, generally ending in death; in tetany as a rule, the child is soon well. Tetanus is in some way connected with injury to the umbilicus, or umbilical cord; in tetany, trauma has nothing to do with the case. In organic diseases of the brain the contractions are usually limited to one side, with other symptoms of brain involvement; in tetany the contractions are bi-lateral.

Prognosis: In children, tetany, when uncomplicated by grave disease causing it, almost always ends in recovery, though it may recur. The duration is from a few days to several weeks or months—indefinite.

Pathology: Since tetany in children is so rarely fatal, and then usually from the complicating or causative disease, but few autopsies have been made, and in these no lesions have been found which seem to bear a causal relation to the disease. Herz says that clinical phenomena indicate that the disease is due to anæmia of the cord.

Treatment: When the cause is known, especially when from diseases of the digestive system, its removal will soon be followed by the disappearance of the disease. Bromide of potassium in doses according to age should be used. Chloral and calabar bean are recommended. Envelope the hands and feet in hot fomentations, or use massage with alcohol and water. A child of fifteen months recovered in one week on gr. ¼ zinc sulphate and gr. $\frac{1}{192}$ atrophia sulphate, thrice daily. This is all that is necessary in children. In adults, canabis indica and morphia hypodermically have been used with good results.—(For discussion see page 587.)

Society Reports.

ALLEGHENY COUNTY MEDICAL SOCIETY.[1]

BY W. C. BANE, M. D.

CHLORATE OF POTASSIUM IN PHLYCTENULAR ULCERATION OF THE CORNEA.

It is almost a century since chlorate of potassium was brought to the notice of the medical profession as a remedial agent. In 1795 Dr. Garnet,[2] of England, used it in the treatment of disease. At one time it was lauded as almost a specific in many of the maladies to which mortal man is heir. However, years of clinical experience determined its real value, and it was assigned a place among the topical remedies. Though valuable when administered internally, in some conditions of the system, it has its deleterious effects,[1] having already caused 47 deaths.[2] Its therapeutic properties may be stated generally as those suggested by its chemical constitution and affinities, as a salt excepsionally rich in oxygen, it has without decomposition, the valuable property, *per se* by its mere presence apparently, of oxygenating or aerating the blood, and by so restoring or exalting this inherent quality of the circulating fluid, influencing to a corresponding degree nutrition and functional activity of the various tissues and organs of the body.[3]

In ulcerative diseases chlorate of potassium has been thoroughly tested during the past 40 years both internally and locally. Under Therapeutics, in the *North Am. Medico-Chirug. Review* for March 1858, p. 387, Dr. Dethan regards chlorate of potash "as an especial and incontestible remedy in ulcero-membranous stomatitis. . . . its topical application is sufficient, and in a short time the mucous membrane recovers its normal qualities and functions."

Dr. Gallaher, of Pittsburg,[4] lauded chlorate of potash in mercurial stomatitis, stating that, "'should there be ulceration of any portion of the mucous membrane of the mouth, I direct a weak solution of the salt to be applied to the denuded part several times a day; generally nothing else is required, the cure being accomplished in a few days." As a local application in ulcers of the lower bowel chlorate of potassium in solution gives excellent results, the ulcers healing rapidly.

I presume chlorate of potassium has frequently been used as a local application in diseases of the eyes, but I have only found one record, that of Dr. Landesberg, of Philadelphia, using it as a topical application in epithelioma of the eye-lids.[5]

Ulcers of the cornea, especially the phlyctenular variety, are frequently met with, usually developing as a little papule or pustule on or near the margin of the cornea. They may develop independently or as a

complication of some existing ophthalmia or catarrhal affection of the nares. A large percentage of the cases are strumous or scrofulous, consequently suffer from nasal catarrh.

The symptoms may vary as to their intensity, but we usually find photophobia, congestion and pain. The variation in the symptoms being influenced by the number of phlyctenules and the constitution of the patient. Constitutional treatment and regulation of the diet, etc., is invariably needed.

The first use I made of chlorate of potassium as a local remedy in ulcers of the cornea was in a case of serpiginous ulcer in Jan. 1882. Case—Mrs. S. C. H., *aet.* 50, constitution feeble. Having exposed herself in doing some out-door work while the weather was rough, that developed an ulcer in the upper, outer quadrant of the right cornea. When I first examined the eye the ulcer was about 2x3 mm. in size. There was photophobia, congestion of the conjunctiva and subjacent tissues; eye-ball, right side of the face and head painful, constitutional remedies prescribed. Locally atropia and weak solution of biborate of soda. One week later the ulcer had doubled in size and depth. Atropia acted as an irritant, morphia disagreed, they were both discontinued. As chlorate of patassium had served me well in ulcers of other portions of the body, I determined to test it on the corneal ulcer, and so directed a 5-grain solution to be instilled in the eye, as warm as could be borne, 3 or 4 times daily. From the time the chlorate was used the ulcer began to heal. Owing to loss of tissue there remained an opacity. Instead of the morphia the patient was given hydrate of chloral, with bromide of potassium, though chloral, when administered internally, acts as an irritant to the eyes in some cases, in this case it did not.

During the past five years of special practice, nearly four years of which I have had charge of the eye and ear department of the dispensary of the Western Pennsylvania Medical College, some 56 cases of ulcer of the cornea have come under my care. About two-thirds of these cases were of the phlyctenular variety. The chlorate has rendered good service in different forms of ulcers of the cornea, but rather better in the phlyctenular than in the other varieties. Not all of these cases were treated with the chlorate, as in some the washed mild chloride was applied, in others the ointment of the yellow oxide of mercury, and in a few a weak solution of the bichloride of mercury.

In the limited experience I have had in the treatment of corneal ulcers and the use of the above remedial agents, my convictions are that the chlorate in about 5-grain solution, used quite warm 3 or 4 times daily is the most soothing, and heals the ulcers more rapidly than any of the other agents tested. True, the warm water itself is of great advantage, but the chlorate is a valuable addition on account of its antiseptic action. It does not prevent bacterial evolution, but it does retard chemical decomposition of organic fluids.

Dr. Lippincott: I never use chlorate of potassium in such cases. We have so many old remedies which will answer the purpose. I have found in my experience that the direct application of very hot water to the cornea is a good thing in these ulcers. The one class to which the doctor refers, generally extremely obstinate, I have treated by the direct application of water at a boiling temperature or steaming. I put a drop of water directly on the exposed cornea so that it steams as it comes out. One drop of the water touches the ulcer, and the effect is marvelous in some cases. The first case I tried it in was a little boy, aged about six years, who had been under treatment for a good while. Treatment had been followed for about three weeks without any material change for the better, and it occurred to me one day to apply the hot water in that way. Before that time could get no dilatation, none whatever, but after the first effort with hot water, the pupil dilated very widely indeed. A good recovery was made. Heat is applied constantly of course, but this was a new application of heat. This hot water treatment, it seems to me, is milder than applying a red hot iron to the ulcer. It seems to destroy less tissues than the hot iron, and it certainly answers the purpose in so far as my experience has gone.

Dr. Bane: I simply wanted to bring this matter out. Hot water is certainly beneficial as Dr. Lippincott has stated, but it seemed to me that the chlorate shows an advantage, at least it has done so in my experience.

Paper by Dr. Small. See page 584.

Dr. Lange: I once saw a tetany follow diphtheria at the time paralysis usually follows. The description Dr. Small has given of his case, fits mine exactly. Tonic contractions of the muscle, lasting in my case ten days. The dorso-cervical muscles were not involved in my case, neither were the muscles of the lower jaw, and the clinical picture as a whole is different from tetanus. At that

time I had not been enlightened by Dr. Small's researches, and scribed this to some obscure nervous affection. I am glad to have heard Dr. Small's pathology, and merely mention my case as his etiology did not include diphtheria. Tetany in the infant is not a very rare disease; it is however in the adult. I do not remember having seen it in an adult. The symptoms given by the doctor correspond to the symptoms in my case. These cases generally recover without treatment.

Dr. Green: At the present time I have in charge a case or two of tetany, and one has been going on a full week. In the first instance, when I was called to see it, they reported that the child had convulsions. The child is 19 months old. There were no convulsions and no indications of convulsions having taken place. None of the usual symptoms that follow convulsions. I did not discover any peculiarity at that time in regard to the muscular contractions. I saw the case again in two days; at that time the discoloration of the hands and feet was well marked. Very tender on pressure, a case that might well be mistaken for rheumatism. The general condition of this child, when I saw her, was slight congestion of the lungs with slight bronchitis, and I discovered afterward that there was some derangement of the stomach. I used an injection of warm water, and when the matter had passed from the bowels, there was a considerable number of pieces of potato that had been fried before taken into the stomach. I think my case corresponds almost exactly with the case that Dr. Small has described. On my first visit, I regarded it as tetany, although I was not able to make a diagnosis. The case was well marked latterly.

Dr. Rigg: I would like to ask a question: Whether the doctor has observed any special contraction of the muscles with reference to the epidemic that has been prevailing for the last year or two? I refer to the epidemic called grip. There has been in my hands quite a good deal of contraction of the muscles, especially of the limbs, so much so that persons have been unable to relax themselves, and would generally require a quarter of a grain of morphine, and I have had to repeat that two or three times in an evening before the muscles would relax so that the patient could rest. I was very much pleased with the doctor's paper, and the question came up in my mind whether there might be some connection between tetany and the influenza of which I speak.

Dr. Ayres: This is certainly an uncommon disease. I have never seen a typical case of it. The cases of Dr. Rigg are not due to tetany, they are doubtless of a rheumatic character, caused by the cold or influenza, and possibly Dr. Green's case is similar. In one respect, the doctor's does not quite agree with the typical cases, and that is, that it was of brief duration, about a week if I remember aright. Tetany is paroxysmal, coming and going. If I understand the doctor rightly, his case was just one of tonic contraction, which relaxed and disappeared, and I believe there was no recurrence.

Dr. Stevenson: I think there are a great many diseases that because they are rare and infrequent are not much written of or talked about. Now tetany is a disease that has been very clearly before the profession for thirty years, yet the fact that perhaps we do not see this disease and do not hear it talked about, makes it seem like something new. Some of the speakers have got the idea that it occurs almost exclusively in childhood. I think I will have to differ from that, for Professor Trousseau, when he first discussed the disease, described it as a rheumatic contraction occurring in nursing women. In his hospital he had seen a number of cases occurring in the nursing wards, and he published a description of them. The paper, as I understand it, did not exactly describe the contraction as I understand the disease. This contraction is a spasmodic affair that comes on and may last a few minutes and may last as long as twelve hours, and relax and come again. A contraction that would last twelve hours would be considered one of unusual duration. Now then, the paper, as I understand the question, describes the disease as terminating in a week. This is possible in a mild case which may terminate within a week and not return, though the rule is to have these contractions repeated frequently during a day or several days, if they are sick long enough, in which the patient will seem well, and the condition will occur and be repeated again and again, and the whole duration of the disease is very frequently several months. I saw a case of this character twenty years ago. It occurred in a pregnant woman. She was ten years married; she had given birth to seven children, and as a result she was very feeble and delicate, worn out, exhausted by her frequently recurring pregnancies; she was all the time either carrying a baby or nursing one during these ten years. In about the sixth month of her pregnancy this condition occurred. She

got spasmodic contractions of the toes, and then of the ankles, and by and by it involved two fingers on each hand and the thumb. She would sometimes have these paroxysms come on and last for an hour, and relax for a time, and come again probably for a week, then perhaps for a week or ten days she would be wholly clear of the spasms, then they would recur again, and this condition contined until after she was delivered of her child. I saw another case of tetany in a boy, a colored boy, who lived in a rather destitute condition; the family were exceedingly poor, and lived in a stable simply weather-boarded with no internal lining. They had few bed-clothes and were scarce of food. This boy was driving a wagon and doing chores of different kinds through the town; he was aged about sixteen years. He drove a milk wagon and was out in very severe weather, and only partially clothed. I think the privation and the cold he was subjected to at home and outside, brought on this tetany. He had contractions of his hands and of his feet and contraction of the abdominal muscles and the diaphragm, and he died. He had no lock jaw, he had none of that sensation around the chest that would indicate tetanus, but this spasm of the diaphragm occurred at intervals. He had one or two slight attacks of it on the first day, he had two or three slight attacks of it in the night, and the next morning he had a severe attack of the diaphragm and died.

DR. SMALL: As I said in my paper, I do not think this disease is mentioned in the common medical text books. The most I have read on it I have seen in the last two or three years in the *Archives of Pœdiatrics*. I presume that I so easily made out a diagnosis of this case, for the reason that in three numbers of that journal, Dr. Smith, of New York, published a very exhaustive article on the subject, and he had some pictures, one of which is almost precisely like the appearance of my patient when I first saw her. His article is very exhaustive, and it may be that he got it up simply as regards tetany in children, and although this article I mention speaks of it in a child, I think I mentioned in several places in my paper as to symptoms in adults, although it was written with a view of describing tetany in children. As to duration, the gentlemen seem not to have understood me rightly. I stated it may last a week or a month or indefinitely. As to diphtheria being the cause, as far as I have observed, I have not seen that given as a cause, nor have I seen influenza given.

SELECTED FORMULÆ.

LOCAL ANÆSTHESIA FOR SLIGHT OPERATIONS.

For operations upon small abscesses, opening fistulous tracts, or removing superficial growths, it is recommended that local anæsthesia be secured by a spray of the following solution:

℞

Chloroform	10 parts
Sulphuric ether	15 "
Menthol	1 part. M.

The anæsthesia which is thus obtained lasts from two to ten minutes.

—*Lon. Med. Record.*

POWDER FOR ACUTE ECZEMA.

La Semaine Medical gives the following prescription of Alexinski for this condition:

℞

Oxide of Zinc	15 grains.
Subnitrate of bismuth	30 "
Powdered starch	1½ drachms.
Powdered Lycopodium	" "

This powder is to be dusted over the parts which are affected, night and morning.

GARGLE FOR ACUTE TONSILLITIS.

℞

Ammoniated tincture of guaiac, Compound tincture cinchona,	of each 6 drachms.
Chlorate of potassium	2 "
Honey	6 "
Powdered gum arabic	a sufficient quantity.
Distilled water	enough to make 4 ounces.

From one-half to one teaspoonful of this should be used as a gargle in a little water every two or three hours.—*Journal de Médecine de Paris.*

PRESCRIPTION FOR TETANUS.

La Semaine Médicale states thay Mayer employs the following prescription in the treatment of tetanus:

℞

Hydrochlorate of morphine	⅙ grain.
Chloral	15 grains.
Bromide of sodium	20 "

Make into one powder, which should be wrapped in wax paper; give from three to six of these powders each day.—*News.*

INJECTION FOR TUBERCULAR DIARRHŒA.

℞

Olive oil	6 drachms.
Guaiacol	10 drops.
Water	8 ounces.
1 yelk of an egg.	

—*Journal de Médecine de Paris.*

ANTISEPTIC GAUZE.

For plugging the uterus, BAR (*La Pratique Médicale*, Feb. 17, 1891) has employed with advantage a gauze medicated with retinol iodoform. It is used as follows: The gauze, after being boiled in strong carbolized water and well dried, is dipped in a mixture, the formula of which is not yet very precise; but the one used in the service of Bar consists of—

℞

Retinol.....15 drachms.
Wax..... 1½ drachm.
Iodoform..... 8¾ drachms.

The employment of this mixture, as applied by means of the gauze, appears to present unusual advantages. Tampons made with gauze, prepared in this manner, are especially useful, inasmuch as they are apt to leave a good coating of iodoform upon the vaginal or cervical service and thus assure complete asepsis of the mucous membrane.

A GARGLE FOR THE RELIEF OF FŒTID BREATH.

The *Revue Générale de Clinique et de Thérapeutique* gives the following prescription for the relief of this condition:

℞

Saccharine, Salicylic acid, Bicarbonate of Sodium, } of each...15 grains.
Alcohol..... 1 ounce.
Essence of peppermint.....10 drops.

A teaspoonful of this is to be placed in a wineglassful of hot water, and used as a gargle, once or twice daily.—*News.*

FORMULA FOR DYSMENORRHŒA.

MONIN (*L'Union Médicale*, March 5, 1891) recommends the following for dysmenorrhœa of chlorosis:

℞

Spirits of melissa..... }
Tincture of saffron..... } of each, 1½ ounces.
Tincture of iodine ..... }

Mix. Twelve drops daily, before each of the two principal meals, for two months.

Every eight days, a warm bath, containing three and one-half ounces of chlorate of ammonia.

A PLEASANT VEHICLE FOR CASTOR OIL.

The following mixture is recommended as an efficient means of disguising the taste of castor oil. The only disadvantage is its bulk in proportion to the dose of oil administered.

℞

Castor oil.....30 parts
Bitter almonds..... 2 "
Sugar..... 30 "
Gum tragacanth..... ½ "
Orange flower water..... 10 "
Water.....120 " M.

—*American Druggist.*

TOPICAL APPLICATION FOR NASAL DIPHTHERIA.

Raulin recommends that the membrane be detached by antiseptic irrigation and the raw surfaces covered with the following:

℞

Lactic acid.....gr. xxx
Carbolic acid.....gr. xlv
Pure glycerine.....one ounce.

—*Revue Gén. de Clin. et de Thérap.*

ANTIPYRINE IN THE TREATMENT OF GONORRHŒA.

In the *Revue Générale de Clinique et de Thérapeutique* it is stated that Brindisi employs the following solution as an antiseptic lotion in the treatment of gonorrhœa:

℞

Antipyrine.....45 grains.
Sulphate of zinc..... 4 "
Rose water } of each 2 ounces.
Cherry-laurel water }

Label, "To be used as an injection."

FEVER MIXTURE FOR CHILDREN.

The following is an excellent fever mixture for a child one year old:

℞

Antipyrine.....gr. viij.
Aq. cinnamomi.....
Syr. aurantii cort.....aa.....f℥j.
M. Sig. ℥j. every two hours until fever subsides.

The antipyrine being soluble, goes into the circulation more rapidly than acetanilide, and so breaks the fever sooner.—*Hollopeter.*

NUTRITIVE ENEMA.

℞

Beef broth (fresh made).....viii ounces.
Wine.....iv ounces.
Yolk of eggs..... ij ounces.
Dry pepsin.....℈j.—iv drachm.

M. Sig. Inject as an enema, in small portions during the day.

—*M. Jaccouds.*

DIPHTHERIA.

Andeer recommends the application every hour or two, night and day, of the following:

℞

Resorcin,.....grain xlviij.
Glycerine.....f℥i. M.

—

A spray of a five per cent. solution of the drug should be used in the room and the following administered internally:

℞

Resorcin.....grain x.
Syrup terebinth.....f℥i. M.

S. A teaspoonful every three or four hours.

—*Centralblatt f. d. Gesammte Therapie* H. 9, 1890.

MIGRAINE.

The following powder is recommended in *La Méd. Moderne* for migraine:

℞

Citrate of caffeine.....1½ grain.
Phenacetin.....2 grains.
Sugar of milk.....4 grains. M.

To be repeated, if necessary, in two hours.

Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

RETINOL: A NEW SOLVENT AND ANTISEPTIC.

In several recent communications, Dr. F. Vigier calls attention to retinol, which promises to be as valuable an addition to our pharmacopœa as vaseline. This substance was discovered by Pelletier and Walter in 1838, but remained without any special medicinal application until 1890, when Balzar used it successfully in the treatment of blennorrhagia and in syphilitic and varicose ulcers of the leg. His pupil, Barbier, continued his studies and made them a subject of an inaugural thesis.

Retinol is prepared by the destructive distillation of rosin by heating rosin in an iron retort. When rosin is thus acted upon four principal bodies come off—*retinpathe*, isomeric with toluene and benzoene, boiling 108° C; *retinyle*, isomeric with cumene, boiling at 150° C; *retinol*, which boils at 238° C; and *metanaphthaline*, isomeric with naphthaline boiling at 235° C.

Retinol has a formula of C_{35} H_{16}, a density of 0.900, and is of a brown or yellow color depending upon whether it is prepared from brown or yellow rosin. Both possess the same solvent and therapeutical properties, but the yellow preparation is preferable. Retinol is of an oily consistence, greasy, slightly bitter, of a slightly acid reaction due to traces of pinic acid; the odor is faint and peculiar, approaching that of the fir tree; and it burns with a fuliginous flame.

The solvent power of this substance is remarkable, and in addition to this it is unirritating, antiseptic and desicative, and exhibits no tendency to become rancid or in any way decompose. It is, therefore, singularly adapted for a large number of pharmaceutical purposes. Among the substances dissolved by it are: salol, 1–10; iodol, 1–50; naphthol, 1–50; aristol, 1–50; camphor, 1–20; chrysophanic acid, 1–40; cocaine, 1–30; codeine, 1–40, and strychnine, 1–40. It is mixable in all proportions with oil of juniper, carbolic acid, turpentine, alcohol and ether. Resorcin, if dissolved in glycerine, may be mixed with retinol, and so may iodoform if dissolved first in a little ether. Iodol is dissolved but soon precipitates as a resinous mass. Phosphorus is also dissolved and the solution remains unchanged indefinitely. Retinol mixes readily with fats, oils, vaseline, lard, lanoline, glycerine, cocoa-butter, etc., and is thus susceptible of use in the preparation of a vast number of ointments. In cases where a liquid is not undesirable, retinol, owing to its antiseptic properties, can with great advantage, replace these bodies. Preparations can be made in the form of ointments, solutions, capsules, etc. Vigier exhibited to the Société de Médecine Practique capsules of retinol-salol, retinol-creosote and pure retinol.

It has already afforded in therapeutics most satisfactory results, and in a large variety of diseases. Desarenes and Bar-

bier have experienced great satisfaction from its use in otology and rhinology, more particularly in purulent otitis, and to favor the expulsion of mucus and overcome the nauseous odor in atrophic rhinitis. In such cases it can be applied by injection, with a brush, or on a wad. In gonorrhœal vaginitis tampons soaked with retinol give very quick results, and a cure within 12 or 15 days. In gonorrhœa in man the injection of retinol gives immediate relief and acts on the discharge better and more rapidly than any other substance employed up to this time. In both affections it acts as an antiseptic and insulating body and is also valuable because it causes no pain and is well supported.

Phosphorated-retinol has been used with great satisfaction in the treatment of cases in which phosphorus was indicated. Vigier refers to over two hundred observations made by Kassowitz, in the treatment of rachitis and scrofula; and to cases of anæmia, chlorosis, dysmenorrhœa, uterine hæmorrhages, muscular paralysis, progressive locomotor ataxia, neuralgias, neuroses, hysteria, glaucoma and zona, treated by such men as Delpech, Curie, Guèneau de Mussy, Brocq and Duhring.

Retinol-salol has been used in urinary diseases; retinol-creosote in bronchitis, phthisis, etc.; and pure retinol in gonorrhœa. In opthalmology, Hubert has found it of great usefulness, especially in gonorrhœal conjunctivitis, and after injuries or operations. As illustrations of desirable combinations, the following are suggested:

℞ Retinol.....10 grams.
Lanoline..... 5 "
Bi-carbonate of Sodium..0.5 "

℞ Retinol.....10 grams.
White Wax..... 4 grams.
Cocoa-butter..... 6 grams.

℞ Retinol..... 8 grams.
Rosin..... 8 "
Lanoline..... 5 "

℞ Retinol, Rosin, Lanoline, } each... 5 grams.

The last is of very good consistency. To these formulæ may be added such other substances as may be indicated.

In diphtheria the following combination may be employed as a topical application:

℞ Retinol.....15 grams.
Naphthol..... 1 gram.
Camphor..... 2 grams.

In blennnorrhagia in man it may be employed as an injection, associated with resorcine in the proportion of 3 to 100, and it may also be administered in the form of capsules alone, or in combination with salol, etc.

In diseases of the skin, as psoriasis, the following prescriptions have been found to be good:

℞ Retinol.....20 grams.
Glycerole of starch..30 "

℞ Oil of cade, Retinol, } .....equal parts.

To stop itching this pomade is recommended:

℞ Naphthol B..... 5 grams.
Retinol .....50 "
Soft soap.....50 "
Prepared chalk.....10 "

In conclusion, the following may be considered the chief points of recommendation for this substance:

1. It possesses remarkable solvent powers; it is not altered by time or light; it is an excellent and permanent antiseptic; its local application does not give rise to pain or irritation; it is very cheap; and, finally, it unites by solution or simple mixture with a large number of the most important substances employed in therapeutics. These certainly are sufficient to justifiy the belief that retinol will soon render important and extensive service as an antiseptic excipient.

CORRESPONDENCE.

ELECTRICITY AND PELVIC SURGERY.

To the Editor:

Sir:—Dr. McMurtry's communication, in your issue of April 25, pleases me. The recent paper of Dr. Keith, of London, which is commanding the respectful attention of scientific men on both hemispheres, contains a most suitable answer to these objections, which, after all, are mere fragments of self-delusion.

If electricity in the diseases of women amounted to nothing, it would have been moribund long ago. If electricity was not

steadily gaining a strong following it would not be met with such enmity by laparotomists. If electricity had not already assumed a place as the greatest of all conservative measures in the treatment of pelvic disease, it would not evoke such hostility from those who fear that their own métier may cease to exist from the encroachments made upon it.

I reiterate, I have never seen a tumor anatomically cured, but I am only one out of many using electrical punctures. Dr. Keith cures them, so does Marsey—are the statements of these men to be sneered at by those who advance statistics of successful laparotomies and expect to be believed?

I have never seen a peritonitis result from a puncture, and I find that the records of such results in the practices of competent men are exceedingly rare. Competent men have no such results, and hence, I repeat, that all this furor about adhesions set up by electricity, is "foolish talk," quite on a par with the statement that "fibroids are caused by electricity." And yet this strange pathological story formed the subject of a strange address, not long ago, before an enlightened body of medical men.

It is proven as clearly as any surgical fact is proven:

1. That tumors have been anatomically cured.
2. That all painful and dangerous symptoms have been arrested.
3. That tumors have been greatly diminished in size.
4. That many cases of salpingitis have been permanently benefited.

The doctor stands on dangerous ground when citing ectopic pregnancy as a shibboleth of the laparotomist. The opinion of able men, surgeons, too, and big ones, is evenly divided as to the respective merits of electricity and the knife in the treatment of these cases. So I reiterate, what is found written in paragraph 2 of my letter, to which the doctor makes reply. The doctor has seen bad results following puncture—hence he condemns puncture.

I have seen deaths caused by laparotomy —so has Doctor McMurtry. Shall we, therefore, also condemn abdominal surgery? Dr. McMurtry says, "the operation of the removal of the uterine appendages arrests hæmorrhage and brings about atrophy of the tumor in less extreme cases, and has a mortality of only two-and-one-half per cent."

Electricity will do the same thing, without endangering life—hence the mortality becomes almost criminal.

Why cut a woman up, if you can accomplish the same result, possibly a better one, without this anatomical recreation?

Incompetent men will practice electricity and have bad results; incompetent surgeons make abdominal sections and have bad results—shall we say the fault is in the method?

Horatio R. Bigelow.

PERISCOPE.

THERAPEUTICS.

THE INTERNAL USE OF MERCURY IN BLENNORRHAGIC RHEUMATISM.

Morel Lavallée (*Le Progres Médical*, April 11, 1891) reports to the *Société Francaise de Dermatologie et de Syphiligraphie* two cases of blennorrhagia successfully treated by the internal administration of mercury. The first patient, suffering from blennorrhagic arthropathy was only relieved by ordinary treatment and by the medicinal waters of Aix. He was cured only after the concomitant syphilitic manifestations were combated by the action of protiodide of mercury administered in pill form. The second case was one of blennorrhagic rheumatism accompanied with muscular atrophy that had resisted all other treatment, but was entirely and rapidly cured by the internal use of mercury. The action of the drug in such cases must be determined by future researches.

The same author referred to a case of poisoning produced by the local application of salol. A patient, with an external otitis of syphilitic origin, introduced into the auditory meatus a large quantity of salol. On next day, *pari passu*, with the appearance of serious constitutional phenomena, a swelling of the auricle, accompanied with a violet hue and vesicles, was noticed, followed by an œdematous angina, resulting from a propagation through the Eustachian tube. The intense dyspnœa produced, was afterwards checked through the influence of emollients. Salol, though well borne by the digestive canal, is, on the contrary, badly tolerated when applied locally.

PATHOLOGY AND TREATMENT OF SYMPATHETIC OPHTHALMIA.

According to Abadie (*Le Progres Médical*, April 11, 1891) who has contributed a paper on the subject to the French Congress of Surgery, sympathetic ophthalmia is a dis-

ease of microbial origin. Following a traumatic injury the wounded eye becomes infected. From the borders of the wound the infection gradually gains entrance into the deep parts, invading the optic nerve, the chiasm and finally affecting the opposite eye. Under such circumstances, the external wound should be cauterized by means of a galvano-cautery, and an injection made into the vitreous of the diseased eye of one drop of a solution of corrosive sublimate (1 to 1,000). After a few days this injection should be repeated if necessary. By this means we are able not only to arrest the development of sympathetic opthalmia, but also to avoid the certain loss of the wounded eye. This treatment is especially applicable in the recent forms of sympathetic ophthalmia when the question of saving the primitively wounded eye should be taken into consideration. When, however, the ophthalmia is provoked by the existence of a painful stump, for example, then, the conservative treatment presents no advantages. In such cases enucleation constitutes the best treatment and should be preferred; and here, again, mercurial rubbings in large quantities and prolonged for a considerable time, should be associated with surgical interference.

HOW TO APPLY SERUM INJECTIONS IN THE TREATMENT OF TUBERCULAR PHTHISIS.

Héricourt and Richet have observed that the introduction of blood from an animal refractory to tuberculosis, as the dog, into the economy of one susceptible to the disease, tends to retard the development of the malady. Lépine (*Lyon Médical*, March 1, 1891) has further studied the subject, and from a series of experiments, especially as to the method of making the injections, has arrived at the following conclusions, which have been communicated to the *Soc. des Sciences Médicales de Lyon:* 1. The liquid could not be introduced into the peritoneum, owing to the difficulty of applying asepsis. 2. Other things being equal, injections of 2 or 3 kilogr. can be introduced. 3. The serum, and not the blood, was the substance injected as it is the serum which possesses germicidal powers. 4. The serum of goat's blood was employed in preference to that of the dog, as that was less offensive to the human blood-corpuscles. From 50 to 100 grammes, in divided doses, were injected hypodermatically every two days. This method was well borne by the patients.

ON SULPHATE OF ZINC IN DIPHTHERIA.

As an experiment, Dr. Kilmer added to a gargle (an ordinary tumblerful of water) about fifteen or twenty grains of sulphate of zinc. Upon my visit the next day, my surprise was great to find that about one-half of the membrane (diphtheritic) had disappeared from a boy's throat, while the diphtheritic membrane in his sister's throat had enlarged to about half an inch in diameter, and the throat in every way looked worse. There was no sulphate of zinc in the girl's gargle. The same treatment was continued another twenty-four hours, at the expiration of which time the exudate had entirely disappeared from the boy's mouth and throat, while in the girl's throat it had again at least doubled in quantity, and the general appearance of the throat was much worse. Believing then that the zinc sulphate was entitled to credit for the boy's rapidly improved condition, the girl was supplied with a gargle identical with that which the boy had been using, and twenty-four hours later not only had the diphtheritic membrane disappeared entirely, but all the swelling and distress had gone also, and both patients were now convalescent, and speedily recovered.—*Med. Record.*

DANGERS OF SULPHONAL.

Although sulphonal is probably one of the safest, as it is one of the most efficacious, among the hypnotics recently introduced, the series of cases published by Bresslauer of Vienna show clearly that it has certain dangers. The degree of peril is difficult to estimate, as the patients were lunatics, and were also apparently feeble; but the fact is significant that out of seventy-seven patients who were treated with the drug, no less than seven showed serious symptoms, and in five of these there was a fatal termination. It ought to be mentioned that the patients had been taking the drug for a considerable time in good doses, and had borne it well until symptoms of disturbance set in, these being great constipation, dark-brown urine, slow, or in some cases rapid but feeble pulse, discolored patches resembling purpura on the limbs, and great prostration. In the cases which ended fatally the cause of death was heart failure, with œdema of the lungs. —*Lancet.*

THE ACTION OF HYDRASTIN UPON THE VASCULAR SYSTEM AND THE UTERUS.

Authorities are divided upon the mode of the action of hydrastin on the vascular sys-

tem. Some have observed an increased blood-pressure and slowing of the heart's action, whilst others affirm that the drug paralyzes the vascular system. The uterine contractions provoked by hydrastin are due, according to some, to the direct stimulation of the muscles and of the cardiac nerves; according to others, to the stimulation of the central nervous system. It was for this reason that Serdsteff had undertaken new experimental researches upon frogs (sixty-two experiments) and upon warm-blooded animals (fifty-seven experiments). These are the results obtained by this experimenter:

Given in a small dose hydrastin provoked, in frogs and in warm-blooded animals, slowing of the heart's movements, owing to a stimulation of the inhibitory apparatus, both peripheral and central. Small doses always increased blood-pressure; by larger doses it was lowered.

These differences depended upon the state of the vasomotor centre. Small doses were not followed by convulsions, and did not paralyze either the respiration or the heart. He thinks, then, that if some observers have verified the paralyzing action of hydrastin upon the vascular system, it must be those who have given larger doses of the remedy. Regarding the influence exercised by hydrastin upon the uterus, the voluntary or rhythmic contractions of this organ would be increased in their strength, their number, and their duration.

Hydrastin does not act *directly* upon the neuro-muscular apparatus of the uterus, but *indirectly* by the intervention of the central nervous system, and that very probably by way of the vasomotors.

In sustaining these obtained results the experimenter counsels the use of hydrastin in all those cases of hæmorrhage where it would be, for one cause or another, unwise to await strong contractions of the uterine muscles, and where, it is of the greatest importance to attack the bleeding through the vessels of the uterus.—*Les Nouveaux Remedes.*

IODOFORM IN CHRONIC EYE CONDITIONS.

Dr. G. Walter Barr says: The use of iodoform as a dry antiseptic dressing has always had a tendency, in my hands, to produce exuberant granulations. This suggested the use of the same substance in cases where it is desired to stimulate cell-growth, and naturally some chronic conditions of the eye offered an attractive field for investigation.

It seemed evident that to attain antisepsis and the stimulating effect of the drug, seen in open wounds, it must be continually kept in contact with the part; this ruled out of the question the almost discarded use of iodoform pencils as rapid, repeated applications; the pure iodoform is much too irritating for use in the eye; and an ointment of proper strength best fulfils the conditions. The strength of the ointment should vary with the amount of stimulation desired and the susceptibility of the eye, for there is an individual factor of susceptibility which is far from constant. From 1 to 5 grains of iodoform to the ounce of vaseline has been found most often of greatest use. *En passant*, it is hard to find vaseline now which is free from some irritating substance (probably acid) left in it in the process of refining. This applies to unguentum petrolei, under whatever trade-marked name it is sold.

The first case in which I used the iodoform ointment was a girl aged 15, who had barely light perception in one eye and an anterior staphyloma in the other. There had been conjunctivitis from infancy, and the entire cornea was opaque in the eye which did not have the staphyloma. Before operating on the latter, it was highly desirable to get the best possible vision in the other eye. The ordinary practice had been exhausted, and a 4-grain iodoform ointment was placed in the eye three times a day. In a fortnight the vision was perceptibly improved, and in three months she could count fingers. This eye never got much better, perhaps partly due to a pathological condition of the optic nerve from a long disuse—from early infancy—although the cornea became gradually clearer. The staphyloma was operated upon, leaving a triangular piece of cornea, about 1.5 millimetres in dimensions on each side, and an iridectomy performed behind it. The corneal remnant at once became opaque in the process of healing; there was total blindness in the eye. A 4-grain iodoform ointment was applied twice a day, sufficient being placed on the everted upper lid to last until the next application. In three months the corneal remnant had so cleared up that she could recognize faces in her limited field of vision. I have never had any but the most gratifying results in treating pannus, however deeply the cornea is affected, by the use of iodoform ointment; the sight has not always been completely restored in the worst cases, but vision has been doubled or improved even more. The length of the period of treatment seems to be in direct ratio to the age of the pannus, but

several months are nearly always required in cases of long standing. The ointment should be applied often enough to keep the cornea constantly covered with it.

In trachoma, the efficacy of iodoform ointment depends on the amount of stimulation required and the strength of the ointment. By varying the strength of the ointment, it seems to me that greater nicety of effect can be obtained than in any other way. Trachoma of years' standing with large granulations, which are best adapted to the compression treatment, quickly succumbs to a 4-grain ointment, applied twice a day. In trachoma and chronic conjunctivitis the iodoform ointment may be used to advantage in conjunction with other treatment, where stimulation is not contra-indicated, by applying it at bed-time; the result is a cessation of the gummy or postulating condition of the lids in the morning.

In indolent ulcers, the results have been as encouraging as in pannus. Sometimes it has been necessary to touch the ulcer with cupric sulphate, but in two cases nothing but the ointment was necessary. In all the ulcer healed much more rapidly when the iodoform ointment was used, and usually without cicatricial cloudiness. Continued use of the ointment soon removed all marks of the ulcer and left the cornea perfectly clear.

The above is a generalization of the results in over a hundred cases of trachoma (mostly of very long standing), thirty cases of pannus, and a dozen cases of corneal ulcer. They seem to me to justify a further trial by others. The points to be remembered are, that much depends on a proper strength of ointment in each case, and that it is not adapted to acute conditions.

Regarding the *modus operandi*, those who are not confirmed microbe maniacs will attribute the action to the cell stimulation seen in the use of iodoform in chronic ulcers and like conditions. Of course, in trachoma and chronic conjunctivitis, something may be due to the antiseptic action of the iodoform, but hardly in pannus, or, perhaps, in corneal ulcer.—*Ther. Gaz.*

HYPERKINETIC ACTION OF CAFFEINE IN LARGE DOSES.

In the section of Pharmacology of the Tenth International Congress held at Berlin, Dr. Petreskn, of Bukaresh, made an interesting communication on the subject of the hyperkinetic action of caffeine in large doses. He prescribes the drug in the following formulæ:

℞ Caffeine.....1·0–2·0 gram.
Ag. melissæ.....140·0 "
Spiriti Vini
Syrupi simplicis....aa....30·0 "
M. Sig. One tablespoonful every half hour.

If necessary, this amount may again be taken within twenty-four hours. The formula for hypodermic injection of the drug used by Dr. Petreskn is as follows:

℞ Caffeine
Natr. Salic. vel benzoica...aa...0·25 gram.
Ag. destill.....1·0 "

The solution can be made with the aid of heat, and the whole amount should be used for one injection. In the majority of cases, the author prefers to give the drug by the mouth, never having observed any digestive disturbances to follow its use. Subcutaneous injections were only resorted to in extreme cases where an immediate action of the drug was desirable, and in which other injections were also called into use.

Petreskn classes caffeine among hyperkinetics of the greatest value for the nervous and muscular systems; it is also a stimulant to the vagus, and its action is allied to digitalis in this respect. He has used the drug successfully in typhoid fever, pneumonia, acute articular rheumatism, erysipelas, influenza, measles and several cardiac affections. His experience lead him to the following conclusions:

1. The therapeutic dose of caffeine is from 2 to 4 grammes daily, by the mouth, or 2 to 3 grammes subcutaneously in doses of 0.25 every two hours.

2. Given in these doses, caffeine is a powerful hyperkinetic both for the nervous and muscular systems. The effect of such a dosage shows itself in a strengthening of the cardiac contractions, together with a slight acceleration, the pulse becomes fuller, the arterial tension increases, the temperature decreases, diuresis increases, and the general feelings of the patients are greatly improved.

3. By means of its hyperkinetic action on the heart and vessels, caffeine becomes the most valuable substitute for digitalis. In certain cases caffeine is undoubtedly preferable to digitalis, and for two important reasons: first, its rapidity of action, especially when given hypodermically, and secondly, on account of the absence of accumulative effects, which permits of its continued use for a long period.

4. Caffeine is invaluable in the treatment of primary or consecutive heart failure. It is also valuable in nervous prostration or in congestive conditions in which the nerve

centres are affected, and which are caused by disease or intoxication.

5. The diuretic action peculiar to caffeine, makes it valuable in the dropsies incident to heart failure, as well as those of a purely renal origin.—*Wiener Med. Presse.*

THE TREATMENT OF PULMONARY TUBERCULOSIS BY HYPODERMIC INJECTIONS OF IODOFORM.

Gavoy, in the *Gazette Médicale de Paris*, details his method of treating pulmonary tuberculosis with iodoform. Morning and night, a hypodermic injection of 30 minims of the solution, of 1 part to 100 of iodoform in oil of sweet almond, is given.

No febrile reaction occurs, and the results are very good. The cough diminishes rapidly, and the characteristic muco-purulent catarrh first becomes more liquid and then ceases. The character of the voice is also improved, and the lungs become more permeable to the air. Inspiration is increased in depth, and the râles become more moist. Other symptoms showing the favorable influence of this treatment are a decrease in the night-sweats and a renewal of the appetite. The therapeutic influence of iodoform over carious bone and pus-corpuscles seems to point to the fact that it exercises an analogous action upon tubercular processes accompanied by resolution and necrosis of the lung.—*Med. News.*

TREATMENT OF MALARIAL HÆMATURIA.

Dr. B. W. Mason has treated five cases of malarial hæmaturia, two of these cases were very bad, one died, the other three cases were seen early and all recovered.

One patient was a girl nine years old, who had been having chills for more than a year. Skin very yellow, pulse 135, temperature 102, bowels had been moved by a dose of salts, the bladder acting every hour or two, passing dark blood. The child complained of pain in head, back and bones of lower extremities. She was vomiting almost incessantly, and the dyspnœa was so great that she had to be raised to a sitting posture and fanned frequently; this was, to him, an alarming symptom. He at once put her upon one grain doses of calomel every two hours until the bowels were acted upon; for the nausea gave Horsford's acid phosphate, which acted nicely. He gave tincture of iron three drops, Fowler's solution one drop every two hours, and spirits turpentine four drops every two hours. This treatment was commenced Tuesday at 11 o'clock A. M. At 8 o'clock P. M., the urine began to look more natural, the skin to clear up, the nausea to subside. The last trace of blood in the urine disappeared at 9 o'clock A. M. Wednesday. Not a trace was to be discovered in discharge from the bladder two hours later. The patient began to improve and was discharged on Saturday, so far recovered as to sit up a little. He left a tonic for her and she made a quick and nice recovery. He thinks the iron and arsenic treatment will do.—*Atlanta Med. and Surg. Jour.*

TREATMENT OF BRIGHT'S DISEASE.

The *Rev. de Clin. et Therap.* publishes the following methods for the treatment of Bright's disease:

(1.) *Classic Method.*—The climateric prescription consisted in the avoidance of dampness and sudden changes of temperature. As to diet, rich or irritant articles of food were avoided, as were also eggs. A pure or mixed milk regime was followed, and such articles as wine, whiskey, liquors and beer were entirely prohibited.

(2.) *Senator's Method.*—All white meats and pork are allowed, and the use of vegetables and starchy articles of food, fruits, fats and milk advised. Senator also recommends the employment of wine mixed with water.

(3.) *Semmola's Method.*—The author observes the preceding treatment and besides advises the employment of the following solution to be given in the course of twenty-four hours:

Iodide of potassium	15 grains.
Phosphate of sodium	30 grains.
Chloride of sodium	75 to 90 grains.
Water	20 ounces.

(4.) *Bamberger's Method.*—Besides a milk diet, tonics and ferruginous remedies are employed. The author highly recommends the following preparations: (I) Pills of perchloride of iron. Of these pills three to six are given per day. Each one contains:

Perchloride of iron	⅓ of a grain.
Pulverized menyanthe (Buckbean)	¾ of a grain.
Extract of gentian, a sufficient quantity.	

—*Univ. Med. Mag.*

MEDICINE.

SOME REASONS IN FAVOR OF THE NON-SPECIFIC PROPERTIES OF GONOCOCCUS.

Erand, of Lyon (*Le Progrès Médical*, April 11, 1891) gives some reasons to sus-

tain the non-specific properties of gonococcus. According to the author, there exists in the normal urethra, a diplococcus, which, under the influence of coloring materials, behaves like the so-called gonococcus. Both secrete a diastase, which, injected into the cellular tissue, produces no deleterious effects; but which, introduced into the testicle of an animal, gives rise to orchitis, to a suppuration of the vaginal sac, followed by atrophy of the testicle. The interference of microbes is not absolutely necessary for the production of the suppuration. From a number of experiments performed, to determine this point of specificity in regard to gonococcus, Erand concludes that it is the ground, so to speak, and not a special property, upon which the virulence of the so-called gonorrhœal germ depends.

ALBUMINURIA IN BLENNORRHAGIA.

In a communication upon this subject, presented to the *Société Fran. de Derm. et de Syphil.*, Balzer (*Le Progrès Médical*, April 11, 1891) has sustained that in acute blennorrhagia, whether simple or complicated with cystitis or orchitis, the co-existence of albuminuria is frequent, generally in the proportion of 12 per cent., although this may be caused also by previously existing complications. This albuminuria may assume an intermittent type, and only lasts a few days. In such condition, the balsamic medication seems to exercise an unfavorable action. It is possible that many of these cases of albuminuria may be due to the existence of venal lesions, but they also form a part of infectious processes. It is, therefore, of the utmost importance to examine the urine for albuminuria in all cases of blennorrhagia.

THE ASSOCIATION OF SYDENHAM'S CHOREA AND RYTHMICAL CHOREA IN A HISTORICAL FEMALE.

J. Seglas (*Le Bulletin Médical*, April 12, 1891) reports to the *Société Médicale de Paris*, the case of a young girl, who, at fifteen years of age, suffered the first stroke of Sydenham's chorea. At nineteen she had a second attack of the same malady. The disorderly movements were general, but most prominent on the left side of the body. On this side the sensibility was diminished, as shown by simple contact and even pricking; the same thing was noticed with regard to muscular sense. There was a slight ovarian hypersthesia, but no symptoms of previous rheumatic nature were observed. The heart was apparently intact. Two months afterwards, the choreic movements, greatly improved, were scarcely noticeable on the left arm. It was noticed at the time that these movements had changed in character: they were no longer inco-ordinate but had assumed a small rythmical amplitude, so to speak. Eight days later, these movements of the left arm exhibited the type of a malleatory chorea. In the intervals, the patient suffered from nerve crisis, such as left hemianasthesia, ovarian hypersthesia and a possibility of being hypnotized.

To sum up, this patient was laboring under Sydenham's chorea, accompanied with some hysterical symptoms. Afterwards this chorea was replaced by the rythmical form, the hysteria becoming, at the same time, pronounced. The author does not believe that in this case we had to deal with two diseases, but only with one affection, the hysteria having assumed, successively, the two different types of the original disease, that is, that of Sydenham's and that of the rythmical chorea.

EFFECTS OF TUBERCULIN ON MONKEYS.

M. Henocque (*Rev. de Thér. Méd Chir.*, March 15, 1891) has recently tried the effect of tuberculin in a monkey which presented no symptoms of pulmonary phthisis. Two days after the first injection the animal, which had exhibited the characteristic reaction, presented dullness and a few râles at the right apex. After the third injection the dullness was more marked on the right side, and began to be perceptible at the left apex. Soon all the symptoms of acute phthisis manifested themselves with intense fever, the animal dying ten days after the last injection after losing a tenth of its weight during that time. The total amount used was 6 milligrammes of the diluted fluid. On post-mortem examination, four tuberculous nodules of the size of a pea were fouud in the right lung, and caseous pneumonia involving two-thirds of the organ in the left. In both cases the tuberculous lesions were surrounded by a zone of very intense red hepatisation. Pieces of the caseous tissues were injected into two guinea-pigs, in one after mixture with sterilized water, in the other with diluted tuberculin. Both animals showed signs of cutaneous and glandular tuberculosis.—*Brit. Med. Jour.*

Grass juice, and bottles of electricity, are the agents which a Paris quack announces as a certain cure for tuberculosis.—*Exchange.*

CONTRIBUTION TO THE STUDY OF HYSTERICAL BLUE ŒDEMA.

Dr. Emile Boix (*Nouvelle Icon. Salpetrière*) recently reported a case of this nature, which is of much interest:

L. G., aged 35, cook, Dec. 13, 1890. Headache, but no alcoholism in family. The patient had *incontinence of urine in bed until he was* 14 *years old;* had rheumatism when in the army and twice erysipelas of the face. This was his fourth attack of blue œdema.

The patient is a blonde with blue eyes, and a feminine expression. He says that his natural disposition is very lively, but that his present trouble has made him melancholy.

Sensibility to the brush completely lost on the right side; sensibility to pain and heat very much diminished. The anæsthetic zone was more marked at the level of the right scapula.

There was a concentric retraction of the visual field on both sides, more marked in the right eye. Right, 55° on the outside, 40° on the nasal side; a second examination gave us 40° on the outside; the left eye is 70° on the outside and normal on the nasal side.

The first thing observed was the exaggerated œdema of the patient's right hand. It has the aspect of a total phlegmon of the hand. The œdema occupies the whole hand, but especially the dorsal aspect which is enormous. The coloration of the hand is habitually violaceous with deeply colored places and others whiter; it has the appearance of marble. The cyanosis is much more marked towards the end of the fingers, but it varies very much in the course of the day, without apparent regularity in its variations, and without being altered by external influences; the hand becoming dark-red with places more or less light, and cyanotic points; at other times very pale, at others entirely cyanotic; at other times it is rosy. The position of the hand makes no difference either in the œdema or in the coloration.

The tumor was hard, but the finger made some depression, from which the swelling recovered with great rapidity, the depressed point being white and the coloration, violet or red, being deepened after removal of the pressure.

The affected (right hand) was colder than the sound hand, the difference in temperature varying greatly. On Dec. 13, at night, the temperature of the affected hand was 64° F., that of the sound hand being 81° F. at the same time, On the afternoon, however, of the same day, the conditions varied, the affected hand having registered 94° F. and the sound hand 76° F. This elevation of temperature was not accompanied with any special redness. This elevation was but for a short time; an hour after we find the right hand colder than the other. The patient called this *a stroke of madness in his hand.*

The anæsthesia in the right hand was absolute for all methods, even deep sensibility was abolished. This anæsthesia was arrested at the wrist-band. The prick of a pin on the œdematous part produced a small drop of black blood, but the flow did not persist.

The arm-pit was the seat of an exaggerated secretion of sweat; in a few hours the night shirt of the patient on that side would be soaking to the waist.

If we analyze the stigmata presented by L. we cannot have any doubt as to the existence of hysteria in man; the narrowing of the visual field and the ease with which hypnotism can be produced show this.

In conclusion: the chief singularity we observe was in the temperature of the patient's right hand; an extreme variation, compared with the left hand, of 16.4° (29.5° F.). It is true that this variation was not produced at once under our eyes, but we have had the man at our disposition only three days. We intended to employ various measures—such as the electric current, etc., for the cure of our patient, and we did, in fact, hypnotize him, hoping to get some effect from suggestion. The next day, however, L. insisted upon leaving the hospital at once and would give no reason for his departure.

We believe he was afraid that his œdema would disappear—for we had given him assurance that we were perfectly able to cure him—and he would be deprived of an infirmity which rendered his entrance to a hospital easy.

Two days after the above disappearance he entered the Pitié, and we find, also, that he has been in the Charité.

It is possible that L. can make his œdema appear at will, as a patient of M. Féréol can, who produces when he pleases various imitations of diseases of the skin, such as scarlatina, variola, etc., which mislead the physicians.

L. did not stay long at the Pitiè, he did not think they showed enough solicitude for his case there; and *that* is worth something as a hysteric note.

PATHOGENY OF DIABETES.

Bouchard has stated that there are no fewer than twenty-seven theories of the cause of diabetes. None are entirely satisfactory. The most important fact discovered in recent years is that diabetes follows extirpation of the pancreas in animals (V. Mering and Minkowski), and numerous clinical observers have since then noted pancreatic disease in conjunction with glycosuria. V. Mering and Minkowski, with most praiseworthy scientific reserve, have abstained from formulating any theory to explain the undoubted fact they have put upon record, and Lépine (*Rev. Scientifique*, February 28, 1891) has discovered an additional fact in relation to pancreatic extirpation and diabetes, which must be taken into account when the true explanation of these phenomena is forthcoming. Healthy blood possesses what he terms glycolytic powers. Fresh blood contains a certain percentage of sugar; if the same blood be allowed to stand at the body temperature for an hour before it is examined, a very considerable portion (20 to 40 per cent.) of this sugar has disappeared. This number (20 to 40) may be taken as the glycolytic power of healthy blood. It is considered that this sugar-destroying power is due to a ferment present in the corpuscles, but especially in the white corpuscles, as the glycolytic power of the chyle is as great as that of the blood, and the portions of the blood richest in leucocytes are richest in the ferment, which may be dissolved out from them by salt solution. In cases of diabetes the clycolytic power of the blood falls to 5, 2, or even 1. In animals without a pancreas there is a similar drop. The pancreas thus appears to be the chief source of the ferment. Lépine believes that the activity of a pancreatic cell is bipolar; by its internal extremity it pours the pancreatic juice into the ducts of the organ, and by its basal extremity it pours into the venous blood and lymph the glycolytic ferment. The absence of diminution of the sugar-destroying power of the blood dependent on pancreatic extirpation or disease is thus a factor, and perhaps an important one, in the causation of an over-abundance of sugar in the blood, and will certainly have to be reckoned with before the true pathogeny of diabetes is understood.—*Brit. Med. Jour.*

Dr. Caius, some four hundred years ago, when an old man, tried to regain his youth by sucking the breast of a woman.

SURGERY.

MICROCIDINE: A NEW ANTISEPTIC.

In representing Berlioz, of Grenoble, Polaillon has presented to the *Académie de Médecine* (*Journal de Médicine de Paris*, April 12, 1891) an experimental and clinical study of the new antiseptic: *Microcidine*. Berlioz believes that all the known antiseptics possess more or less disagreeable properties, and cannot be manipulated carefully enough, owing to their insufficient solubility in water; they are such as the salts of mercury, phenol, naphtol, thymol, salicylic acid and boric acid.

He has thus found, from a research upon the subject, a new medicament which, while it possesses feeble toxic properties, is a true caustic, perfectly soluble in water and has no odor or taste. Such a drug is microcidine, a combination of naphtol and soda.

It destroys the staphylococcus albus and the microbes of anthrax in solutions of 0·20 grammes per 1000; it acts similarly on the bacilli of Eberth and the baccillus coli-communis in the strength of 0·25 grammes per 1000. It also kills in the course of *one minute*, in solutions of 5 grammes per 1000, the microbes of saliva, of the pus of osteomyelitis and of puerperal septicæmia. Its antiseptic power is ten times greater than that of phenol, and twenty-eight that of boric acid.

Its minimum fatal dose for rabbits and guinea-pigs, is 0·164 grammes administered intravenously and 0·35 grammes by hypodermatic injection, per kilogramme of the body-weight. It is, therefore, less toxic than naphtol itself.

The solubility of microcidine in water is very pronounced; one gramme of it is readily dissolved in three cubic centimetres of water. In ordinary therapeutics, and even in very large doses, microcidine does not exercise a powerful caustic effect; it does not irritate wounds, and as, on the other hand, it has no odor, it may be employed for toilet purposes. Neither has it any deleterious action on surgical instruments or on clothing.

Microcidine lowers rapidly in animals both normal and febrile temperatures, and is eliminated by the kidneys, rendering the urine non-putrefactive.

Microcidine has been employed with success in a large number of infected and surgical wounds. It may be used in solutions varying from 5 to 3 parts per 1000.

THE TREATMENT OF SYPHILIS.

The following is the therapeutic method which I ordinarily employ in the treatment of syphilis:

As I have already stated, I do not generally give mercury until the onset of the secondary symptoms, although I have carefully used the mild mercurial preparations in the local treatment of the primary lesion.

According to the intensity of the phenomena observed, I prescribe to the patient daily mercurial rubbings, in doses varying from two to four grammes (30 to 60 grains) for a period of fifteen days; then I allow the patient to rest from two to three weeks, according to the case, and I continue in this manner during the first ten months.

In the course of the periods of treatment and similarly during the intervals, I am careful as regards the local treatment of syphilides by means of the mild preparations of mercury. For cutaneous syphilides, I employ the drug in the form of ointments, solutions or lotions.

In certain forms of rebellious cutaneous syphilides, I advise general baths, in each of which may be put seven grammes (105 grains) of corrosive sublimate. It will be unnecessary for me to say that I particularly insist in the observance of mouth hygiene, on cleanliness, general hygienic measures, and that I always endeavor to build up, as much as possible, the system of my patient. In well-to-do cases, I advise a sojourn in the country or by the sea-shore.

At the end of from six to ten months, I do not prescribe the mercurial frictions for a longer period than ten days, and I then advise my patient an interval of repose varying from three to six weeks or even two months, according to the case. This method of treatment is followed to the end of the first and during the second year of the disease.

I am in the habit of administering sudorifics, purgatives and out-door exercise, in order to make the mercury, as it were, circulate through the economy and thus avoid cumulative effects. In exceptional cases, where the patient suffers from persisting headaches or pains in the bones (osteocoes), and where the symptoms do not yield to mercurial medication, I prescribe for the time being, from two to three grammes (30 to 45 grains) of iodide of potassium in combination with from fifty decigrammes to one gramme (7½ to 15 grains) of bromide of potassium.

From the end of the second year my treatment varies greatly, according to the case. If after a certain time the individual is free from syphilitic troubles, I observe the custom of ordering every three months, and during a period of ten days, rubbings of mercurial ointment two to three grammes (30 to 45 grains), and for a few weeks after the inunctions, I administer two to three grammes of potassium iodide, generally after the principal meal, or at night in a glass of milk.

I need not say that when syphilitic phenomena have manifested themselves, I have resorted to a treatment sufficiently adequate to combat the severity and duration of the accidents observed. If at the beginning of the third or fourth year, my patient remains free from all syphilitic manifestations for more than a year, I am in the habit, by way of precaution, of prescribing twice a year, that is, in the spring and fall, mercurial rubbings for a period of ten days. One month after this operation, I order my patient to take, for a space of three weeks, iodide of potassium in thirty grain (two gramme) doses.

If he comes to me after the fourth year, having apparently, for a long time, escaped from syphilitic phenomena, I recommend, by way of precaution, a continuance of the same method of treatment; but if there is the least suspicion of any syphilitic phenomena, I advise him to consult a specialist.

In a general way I try to avoid, as far as possible, the pushing of the treatment by mercury and potassium iodide, the effects of which I have reason to fear. I have many times seen alterations of the economy following the abuse of these therapeutic agents, and, as a consequence, serious neurasthenic phenomena.

I have, likewise, often observed that these neurasthenic symptoms, with or without the presence of dilatation of the stomach, have been mistaken for phenomena of cerebral or cerebro-spinal syphilis. I have also noticed that the continuance of this mercurial and iodated treatment, which has been the very cause of these nervous troubles, has gradually increased the severity of these. Serious consideration of the subject, at such moments, has led me to make the following observations: An individual contracts syphilis. He consults a syphilographer and is by this well treated. Vexation, excesses, bad hygiene, the abuse of mercurial and iodated preparations, all contribute to produce in the patient the neurasthenic symptoms referred to, chief among which are headache, vertigo, change in the individual's character, and disordered memory. Under such circumstances the

physician is liable to diagnose the case as one of cerebral syphilis. Once made, this diagnosis is followed by a simple and natural consequence. The specific treatment has been insufficient, and, therefore, it is further pushed. In spite, however, of this measure, the nervous phenomena do not diminish; on the contrary, they are increased. The patient again consults his physician and this, in turn, increases the doses of the remedies. Thus, the undue persistance of the specific medication renders worse the neurasthenic condition, a condition which has been produced, in many cases, by the abuse of such a treatment, an error of diagnosis, and by the non-observance of the common rules of hygiene.

I have at length treated of the danger resulting from the abuse of the specific treatment, and of the diagnosis of neurasthenia which is frequently mistaken for cerebral syphilis, chiefly because I am now authorized to say that I myself have, at some time, labored under the same errors.

I have afterwards made up for my faults in many instances where I have entirely subdued neurasthenic phenomena by the simple suppression of a specific treatment instituted for a pretended cerebral syphilis.

Such are the principles which have guided me.

I will conclude by saying that I do not prescribe the internal administration of mercury when I can use this remedy otherwise, as that method, as has been shown by Jullien, is more apt to produce digestive, and hence, neurasthenic, disorders, than the external application of the remedy.

I employ the drug internally in those cases where, owing to various causes, the rubbings are repulsive; in those, where it is advisable to keep secret the ingestion of the drug, as, for example, married women; in those that owing to an irritable skin, can not tolerate the local applications (generally this inconvenience can be avoided by employing mercurial ointment newly prepared with fresh benzoated lard, cleansing the part twelve hours after the application, afterwards washing and powdering it); in those where it is absolutely necessary to conceal the treatment. and finally in those cases that, like commercial travellers for example, will not submit themselves to the local use of the drug.

In regard to the hypodermatic injections of the soluble or insoluble salts, I only employ them in hospital practice, especially in the case of public women, since these, as a general rule, do not take the medicament in other forms prescribed.—Prof. H. Leloir, in *Journal de Médecine de Paris.*

ZINC PASTE AS A DRESSING.

Drs. Cordua and Glum have experimented with Unna's modified zinc pastes as a surgical dressing (the thicker paste consists of zinc oxide 10 parts, gelatine, glycerine and water each 30 parts, and the thinner one, of zinc oxide 10 parts, gelatine 20 parts, glycerine 30 parts, and water 40 parts). They found this application especially useful in the treatment of granulating cavities and wounds. After the skin has been disinfected with a 1 to 2,000 sublimate solution and dried, the paste, which has been warmed over a water-bath, is applied in a broad streak around the wound at a distance of 1 to 2 centimeters from the margins, with a thick brush, and then a thick layer of iodoform gauze is pressed with moderate firmness upon the wound surface and the surrounding area covered by the paste. According to the situation of the wound, the layer of gauze and surrounding skin may be brushed with the thin zinc paste, and thus made to adhere firmly, or the dressing may be secured by one or two turns of a bandage, and the paste applied over both. Immediately after, and before the paste has become dry, its surface is lightly covered with cotton, which will thus prevent adherence of the clothing. In this way a perfectly fixed dressing is obtained, which has proved especially useful on the neck, chest, shoulders, hips, the upper third of the arm and thigh, where dressings are usually retained with difficulty. In cases of ulcers of the leg, after disinfection, the sore is covered with iodoform gauze, and the leg enveloped firmly in a mull bandage, over which is applied a layer of paste and then another bandage. This dressing may be left in place for eight or more days. If applied to hairy parts of the body the hairs must be shaved off for a wide distance around the wound.—*Wiener Medizin Presse,* 1 and 2, 1891.

ACETANILID FOR CHANCRE AND CHANCROID.

The *Journal de Médecine,* January 25, 1891, states that Basilevitch reports in *Nouveaux Remedes,* November, 1890, that cicatrization took place in a short time as a result of sprinkling acetanilid on the surface of the ulcers in one case of chancre in a woman and in two cases of chancroid in men.

In these cases acetanilid has the advantage over iodoform of being inodorous, and that large doses do not give rise to toxic manifestations. It is also less expensive than iodoform—an important consideration, especially in dispensary practice.

GYNÆCOLOGY.

SUBCUTANEOUS INJECTIONS OF ETHER IN PUERPERAL ECLAMPSIA.

An interesting supplement to the treatment of puerperal eclampsia, is offered by Dr. Perron, and quoted in the *Wiener Medicinische Wachenschrift*, April 12, 1891. The case recorded was that of primipara, twenty years old, who was seized with eclamptic convulsions two hours after delivery. Chloral in liberal doses, blood-letting, and even inhalations of chloroform, had been tried without avail. The convulsions, which had begun at eight in the morning, continued with unabating severity to return every half hour until noon and then became almost unremitting. The patient lay convulsed with severe dyspnœa and deeply cyanosed, her breathing was labored and stertorous, and death was momentarily expected. Dr. Perrin then injected subcutaneously a syringeful of ether, and in a few minutes the respirations became more regular and less labored. Fifteen minutes later, another similar injection was made, and a third injection two hours later. After the second injection the convulsions ceased entirely, and the patient made a speedy recovery. It is to be noted that no albumen was found in the urine.

PORRO'S OPERATION: PUERPERAL HYSTERECTOMY.

Dr. Joseph Price, in the *Annals of Gynæology,* calls attention to the present success in supra-vaginal extra-peritoneal hysteroctomy for fibroids which has greatly confirmed our confidence in the Porro operation over the Cæsarean.

The present low mortality has induced many operators to do the Porra—a complete and perfect operation and a wise practice—as it saves the patient from the risk of a subsequent section, taking away from the Cæsarean section the most important factor in its dangers—the succulent uterus with its incision.

In his discussions on supra-vaginal hysterectomy, he has endeavored to show that an uncomplicated operation of this sort, with the extra-peritoneal treatment of the stump, is, under the improved technique, an operation of comparatively little danger. He had no deaths from this procedure in his last forty consecutive cases, including two Porros. The operation, in the hands of all trained men, accords with my experience.

The complications of hysterectomy, when no important viscus is involved and the adhesions are simple, are not to be feared. In the Cæsarean section the danger of hæmorrhage is ever present; in the Porro operation the uterus is strangulated at once, thus obviating this complication. The Porro operation clearly has the advantage in these essential points: first, in absence of danger of hæmorrhage from uterine incision; second, in the extra-peritoneal treatment of the cut uterus; third, in the greater rapidity of operation. The results in the Porro operation should surpass those of ordinary hysterectomy for the following reasons: first, there are very rarely adhesions unless electricity has been used; second, there is no implication of any important viscus, and, accordingly, less hæmorrhage; third, less shock. In the Cæsarean section the suturing of the uterus greatly prolongs the operation, making a time consideration that is one of the most important in abdominal surgery. The factors of uncertainty in the healing of the uterine incision put our established ideas of exact surgery at sea; it is impossible to put it at rest. The uterine tissue is not stable, but is undergoing metamorphoses and degeneration; in no other part of the body do we find such a condition, creating such dangers of leakage and consequent peritonitis. This is all done away with in the extra-peritoneal treatment of the succulent stump; here the use of the serre-nœud is the ideal treatment, as it can be contracted upon the shrinking stump and hæmorrhage absolutely controlled.

Considering the sociological side of the question: Have we a right to sterilize a woman? We have not, if she is simply a propagating organism. If we take a higher view, she has the right to the best she can attain to, physically as well as mentally and morally. We should not leave her in jeopardy from a future peril. Again, the children from this class of women—deformed, rachitic, illy developed—often die young, and are at best but illy fitted for the battles of life.

Nearly one-third of the inmates of the New York hospitals are well able to pay for medical attendance.—*Ex.*

OBSTETRICS.

APPARENT GROWTH OF THE PLACENTA AFTER LABOR.

Dr. W. P. Chunn related to the Gyn. and Obs. Soc. of Balt., an instance of a patient who was twenty-eight years old, and had been married five years, She had had no children at full term, but had had three miscarriages. The first and second miscarriages occurred at about the fourth month of gestation. The last miscarriage occurred about May 10th, 1890. She had missed one period, and believed herself to be about six weeks pregnant. On the 10th of May she began to have bearing down pains and hæmorrhage with the expulsion of blood clots, lasting some three or four days. Then the pains subsided, the hæmorrhage ceased and I regarded the uterus as empty. On the 12th of June, however, she was again seized with violent pains, and during the night was delivered of a placental mass larger than a man's fist, which I saw the next morning; the patient, as well as myself, was surprised. The fœtus was searched for but no sign of it found.

THE POLYURIA OF PREGNANCY.

Dr. Voituriez (*Arch. de Tocol.*, December, 1890) concludes, after a study of this subject, that, in the course of gestation, polyuria of a type entirely confined to pregnancy is sometimes observed. In such cases the urine is clear, slightly acid, and of normal composition, excepting that the proportion of water is greatly increased, so that the specific gravity is low. Sugar and albumen are alike absent, and no cystitis is present in cases of this affection. Polyuria of pregnancy is probably more common than is generally believed. The only way of authenticating a case is carefully to collect all the urine passed every twenty-four hours. The disorder is not usually detected until the middle of the pregnancy. It rapidly disappears after delivery. In nature it is exceedingly mild, and it appears to endanger neither the mother nor the child. Dr. Voituriez describes a case where a pregnant woman was compelled to make water over twenty-four times in twenty-four hours, passing over seven pints of urine daily. She suffered from slight thirst. Yet she was safely delivered of a living (first) child, which weighed nine pounds. Tarnier's forceps had to be used. Directly after delivery polyuria ceased and never recurred. The secretion of milk was normal. Bromides and belladonna had been administered, but proved useless.—*Albany Med. Ann.*

PÆDIATRICS.

SALICYLIC ACID FOR THE PREVENTION OF SCARLET FEVER.

Sticker reports the observations of G. de Rosa, who administered salicylic acid, in doses of one to five grains daily, to sixty-six children exposed to infection during an epidemic of scarlet fever. Twenty-seven cases of the disease existed in the building, when administration of the drug was commenced. Only three of the sixty-six contracted the disease, the failure in these being ascribed to a longer exposure to infection.—*Centralblatt für klin. Med.*

ANTIPYRETICS IN CHILDHOOD.

Demme (abstract in *Therapeutische Monatshefte*, Feb., 1891) believes that a moderate elevation of temperature of a few days' duration is best treated without any antipyretic drug. When, however, a temperature of 104° F. is reached and maintained, these drugs are of decided importance, as in typhoid fever, rheumatism and bronchopneumonia. In diphtheria, the acute exanthems and croupous pneumonia, on the other hand, they are to be avoided.

Salicylate of soda he employs in rheumatism, in daily doses of 7½ to 45 grains for children of between 2 and 15 years; and salol in about the same doses. He recommends thallin sulphate in typhoid fever in doses of ⅛ to ¾ grains for children from 3 to 15 years; antipyrine in the first stage of broncho-pneumonia in several hourly doses of three to fifteen grains; in later stages of the same disease quinine in equal doses. Acetanilide is efficient in the high temperatures of pulmonary tuberculosis, one to three times daily, in doses of ¾ to 4½ grains. Phenacetin, he thinks, is best given in several full doses, such as 1½ to 7½ grains, according to age.—*Univ. Med. Mag.*

TREATMENT OF CONVULSIONS IN CHILDREN.

T. G. Davis recommends, if the patient is cyanotic, a few whiffs of amyl-nitrite, followed by inhalations of chloroform and hypodermic injection of tincture veratrum viride—one-half drop for each year up to six years.

HYGIENE.

A RETROSPECT OF THE SUCCESSIVE EPIDEMICS OF CHOLERA IN EUROPE AND AMERICA FROM 1830 TO 1890.

Dr. WILLOUGHBY, in a paper before the Epidem. Soc., after alluding to the doctrine of epidemic influences, telluric and atmospheric conditions, and other unknown agencies as at one baseless and needless, and to the opposite delusion, prevalent in the south of Europe, of its being infectious in the same sense as small-pox, asserted that all the independent and scientific students of the subject in Europe and America were now agreed that the vehicle of contagion was contained in the evacuations, that it was thus carried by fomites as soiled clothing, etc., while persons suffering from the disease, even in unrecognized and mild forms, infected the soil and water of places through which they passed. Insanitary conditions favored its development, but the most insanitary towns—as Rome, Seville, and others—had escaped, since they had been provided with pure water supplies. The incubation period he believed to be as a rule from one to two days, four being an ample limit for quarantine purposes. Its transportability and conveyance wholly and solely by human intercourse was proved not only by the progress of every epidemic having followed the great routes of trade and pilgrimages, but by the rapidity of this progress having corresponded to the facilities for travel, whether by caravans, river boats, railways, or ocean steamers, quoting in this connection Dr. de Renzy and others as to the altered corcumstances of travel in Northern India; and he thus explained the immunity of Australia and Chili, virtually the most isolated communities in the civilized world. It was, he said, in 1821 that cholera, so far as was known, first advanced from India westward, reaching Astrakhan in 1823, but subsiding until 1827, when a fresh wave swept over Persia, entering Russia in 1829. In 1830–31 it was fomented by the war in Poland; in 1831–32 it spread over the whole of Europe; and in 1832–33 over North America, lingering in each continent for about two years longer. It was remarkable, and totally inconsistent with the theory of conveyance by winds, that, though some cases had occurred on board ships in the Medway as early as July, 1831, it did not reach London till February, 1832, having effected a landing at Sunderland and travelled *via* Newcastle, Edinburgh, Glasgow, Belfast, Dublin, and Cork, whence it was at length brought to London. A wave rolled over Persia, Arabia, and Syria between 1836 and 1839, but retired again. In 1840 it entered China, then passed westward through Central Asia, re-entering India from Afghanistan and through North Persia, reaching the Caspian and Black Seas in the summer of 1847. Following the military road then in course of construction from the Caucasus to Moscow and the river highway of the Volga, it was intensified and spread by the fair at Nijni Novgorod and the massing of the Russian, Austrian and insurgent Hungarian armies on the Danube, and in the course of 1848–49 had attacked every country in Europe except Denmark and Greece, which were saved by stringent quarantine. It extended to America in 1849, but died out in the course of the following year. The epidemic of 1854 was not strictly a separate invasion, but rather a resuscitation of the last, which had lingered in the south and east of Europe and the west of Asia until called into fresh activity by the Crimean war. Every country in Europe and America was again invaded. The incidents of the outbreaks in America threw great light on the conveyance of the disease by fomites. The epidemic of 1865-66, which was the first to come wholly by the Red Sea, spread rapidly over Europe and America; but had scarcely subsided when a fresh explosion occurred at the Hurdwar fair in India in 1867, whence it was carried to Persia and Russia, being reintensified *en route* by the pilgrimage at Great Mesched in 1868 and the fairs at Nijni Novgorod in 1869 and 1870.

At the close of the Franco-German war, every country in Europe was attacked except Great Britain, and America succeeded in averting its importation until 1873. By 1874 it had, however, disappeared everywhere on this side of India. In 1881-83 it prevailed in Arabia and Egypt; in 1884 it made its appearance in France, and soon raged throughout Italy and Spain. The influence of pure water supplies was brought into special prominence, not only in the case of single towns in Italy and Spain, but in the almost complete immunity enjoyed by Germany, which had previously suffered heavily in every epidemic. Cholera lingered in the south until the end of 1885, since which date it had been absent from the continent of Europe until the isolated outbreak in Spain in 1890. This, Dr. Willoughby was convinced, was not imported

from the East, but was a recrudescence of the epidemic of 1884-85, brought about by excavations in infected ground. Still cholera had, since 1888, been slowly but steadily advancing by the Persian Gulf and the extensions of that route. It had last year reached the shores of the Caspian and Black Seas, and had raged at Mecca, though Egypt had almost miraculously escaped, and it had persisted at Aleppo and the Syrian ports certainly as late as January of the present year. He had little doubt that, as its march had closely corresponded with that in 1845–47 we might expect history to repeat itself in an invasion of Southern and Eastern Europe during the coming summer, unless, as in 1823 and 1839, it should retire, after having thus approacned the confines of Europe. If, however, it had not already really died out, the vast increase of communication between the two continents rendered such recession less probable than it was fifty years ago. The paper was illustrated by a number of maps showing the great routes and the course of each epidemic in Asia, Europe and America. Sir W. MOORE gave his experience of an outbreak at Aden following the unloading of a cargo which was proved to have been soiled with cholera excreta at Bombay, the crew remaining healthy; and Mr. MURPHY alluded to Dr. Simpson's having traced the occurrence of cholera on board certain ships moored in the Hooghly to an infected milk supply. Surgeon DAWSON argued in favor of epidemic influences, but Dr. WILLOUGHBY, in reply, urged that in the case of the ships at sea quoted by Mr. Lawson, the crews who must have been most exposed to atmospheric influences escaped, the steerage passengers only being attacked; while such negative evidence as that of the Southampton and Theydon Bois outbreaks in 1865 was worth nothing. It was more probable that some one suffering from mild and unrecognized cholera had crossed over from France, and, leaving the infection behind, had perhaps returned, than that Mr. Groombridge had inhaled it with the sea breezes on Weymouth pier. Such difficulties were incident to all cases even of smallpox, the source of which no one doubted. The PRESIDENT complimented Dr. Willoughby on having brought within the compass of a single paper a mass of information hitherto inacessible, and on having by his demonstration of the almost "postal regularity" with which the late epidemic followed the routes of travel by road, rail and steamships, regardless of prevailing winds, but refusing to cross the Scandinavian and Carpathian mountain ranges in mid-winter, given the *coup de grace* to the doctrine of atmospheric waves, which, in the case of this disease, he had until that evening accepted.—*Lancet.*

MEDICAL CHEMSTRY.

HÆMATOPORPHYRIN IN THE URINE.

A number of cases have recently been recorded in which the iron-free derivative of hæmoglobin, called hæmatoporphyrin, has been described in the urine. The first recorded observations of this occurrence were made by MacMunn in June last, and the most recent, by Salkowski, are published in the *Centralb. f. d. med. Wiss.*, 1891, No. 8, p. 129. The three cases mentioned by Salkowski were in women, and one case ended fatally. The cause of the occurrence of this abnormal substance in the urine is supposed by Salkowski to be the administration of sulphonal. This is, however, an abnormal action of the drug, and therefore appear to be due to individual idiosyncrasy.

TESTING FOR IRON IN ORGANS.

Zaleski (Die Vereinfachung von makro- und mikrochem. Eisenreaction, *Zeitsch. f. phys. Chemie*, xiv., p. 274, 1890) gives a simple method for detecting histologically the presence of iron in organs. Small pieces of the organ are hardened first in 65 per cent. alcohol, and then in 60 per cent. alcohol, to which a few drops of yellow ammonium sulphide are added. In twenty-four hours, if iron be present, the tissue has a greenish appearance, and on making a section the exact distribution of the particles of iron sulphide is readily detected by the color reaction.

NEWS AND MISCELLANY.

EXPERIMENTS recently made in France with a view to discovering the amount of vitality in specimens of trichinæ show that, though they be subjected to a temperature of 25° below zero for two hours, they again become as lively as ever on a return of a normal amount of light and heat.

THE University of Bonn is stated by the correspondents of the London papers to have ordered that the use of the Koch injection shall be discontinued in all the clinical hospitals under its jurisdiction.

CH. MARCHAND'S

PEROXIDE OF HYDROGEN

(MEDICINAL) H_2O_2 (Absolutely Harmless.)

Is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a Nostrum.

A REMEDY FOR DIPHTHERIA; CROUP; SORE THROAT, AND ALL INFLAMMATORY DISEASES OF THE THROAT.

OPINION OF THE PROFESSION.

Dr. E. R. Squibb, of Brooklyn, writes as follows in an article headed "On the Medical Uses of Hydrogen Peroxide (*Gaillard's Medical Journal*, March, 1889, p. 267), read before the Kings County Medical Association, February 5, 1889:

"Throughout the discussion upon diphtheria very little has been said of the use of the Peroxide of Hydrogen, or hydrogen dioxide; yet it is perhaps the most powerful of all disinfectants and antiseptics, acting both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. The few physicians who have used it in such diseases as diphtheria, scarlatina, small-pox, and upon all diseased surfaces, whether of skin or mucous membrane, have uniformly spoken well of it so far as this writer knows, and perhaps the reason why it is not more used is that it is so little known and its nature and action so little understood. . . . Now, if diphtheria be at first a local disease, and be auto-infectious; that is, if it be propagated to the general organism by a contagious virus located about the tonsils, and if this virus be, as it really is, an albuminoid substance, it may and will be destroyed by this agent upon a sufficient and a sufficiently repeated contact. . . . A child's nostrils, pharynx and mouth may be flooded every two or three hours, or oftener, from a proper spray apparatus with a two volume solution without force, and with very little discomfort; and any solution which finds its way into the larynx or stomach is beneficial rather than harmful, and thus the effect of corrosive sublimate is obtained without its risks or dangers. . . . ."

Further on Dr. Squibb mentions that CHARLES MARCHAND is one of the oldest and best makers of Peroxide of Hydrogen, and one who supplies it to all parts of the country.

CAUTION.—By specifying in your prescriptions "**Ch. Marchand's Peroxide of Hydrogen (Medicinal),**" which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon. Never sold in bulk.

PREPARED ONLY BY

A book containing full explanations concerning the therapeutical applications of both CH. MARCHAND'S PEROXIDE OF HYDROGEN (Medicinal) and GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application. ☞ Mention this publication.

CLINICAL LECTURE.

CONVULSIONS DEPENDING ON RICKETS—VARICELLA—SPECIMEN FROM A CASE OF CEREBRO-SPINAL MENINGITIS.

BY L. EMMET HOLT, M. D.,

PROFESSOR OF DISEASES OF CHILDREN AT THE N. Y. POLYCLINIC, ETC.

CONVULSIONS DEPENDING ON RICKETS.

Gentlemen:—Our first patient this morning is a little boy, six months old, who, his mother states, was perfectly well until about two months ago. Without any premonitory symptoms he was then taken with general convulsions, which were repeated during the following twenty-four hours, the child passing, at short intervals, from one convulsion into another. After this attack, he was apparently well, until about two weeks later when the same symptoms were repeated, the second series of convulsions being more severe than the first ones had been.

Ten days before he came here he had a third series of convulsions, similar to those which had preceded. The intervals between these different attacks were, however, free from symptoms of any kind, and since the last attack he has been apparently well.

At first sight, this boy seems to be well nourished and healthy; he is plump and weighs about 20 pounds, is not anæmic, holds his head up, has no evidence of paralysis, no fever, he is bright and apparently notices everything. What causes of convulsions are we to consider in such a case as this? Organic disease of the brain is apparently excluded, first, because his symptoms were not noticed until some months after birth, and second, because the labor was a natural one, no forceps were used, there is no rigidity of the neck, no spasms of the extremities and intellectually the child seems to be very well developed. The probabilities are that in a case like this the convulsions are of reflex origin, and the first thing to suspect as the source of such irritation in a child is the gastro-intestinal canal. The mother states, when questioned about this, that she now is nursing her child exclusively, but that about the time of the first attack of convulsions, she gave him coffee, soup, toast, and some other varieties of solid food. At the present time, however, these have been discontinued altogether. Could the same cause have been operative in both instances, or are we to look further for the cause of these convulsions?

In many cases of convulsions in infancy no cause can be found clinically, and the convulsive habit becomes finally established, the attacks recurring at shorter and shorter intervals, until the patient passes into a stage of confirmed epilepsy. Is this case to be looked upon in such a light?

Constipation is another cause of convulsions in children, but the mother states that this child's bowels have been always regular.

There is one strongly pre-disposing cause to convulsions in infants, and one that must never be overlooked by the physician, and that cause is rickets. The nervous system of young children is exceedingly prone to convulsive attacks, and in rachitic children this proneness is very much exaggerated. Never permit a young child, after recurring attacks of convulsions, to pass through your hands without first of all making a careful and exhaustive examination for the earlier signs of rickets.

What signs are we to look for in a child of this age? First, examine the head. What do we find here? The head of this child is of normal size, but the anterior fontanelle measures two inches and a half in one diameter by one inch and a half in the other. The sutures have not united, and over the posterior part of the parietal bone I can feel several soft spots in the cranium about the size of a nickel. These are spots of cranial tabies, and are, of themselves, almost conclusive proof of rickets. Their position on this part of the head shows that they have

been produced by pressure, the osseous elements of the skull being here absorbed and the membranous portions alone remaining intact. The bony deformities, such as beaded ribs, enlarged epiphyses, pigeon-breast, bow-legs, etc., belong to a later period of this disease, and are not to be expected here.

One other point in the history should be inquired into, namely, as to the presence of head-sweats. The mother states, upon inquiry, that for several months past, while the child has been asleep, she has noticed a profuse perspiration of the head and neck, sufficient to wet the pillow considerably. There seems, then, to be very little doubt that this child who, upon first sight, seemed so fat and healthy, is the subject of rickets. Rickety children are often fat, but their tissues are usually flabby. This child's tissues are not especially so, nor is he anæmic. There is to my mind no doubt that the underlying and predisposing cause for the convulsive seizures is rickets. In such children we find that a very slight exciting cause is sufficient to bring on attacks of convulsions, second attacks always move easier than the first ones, and subsequent attacks from still more trivial causes. The exciting cause of the first attack, I judge in this case, was the improper food the mother gave the child, but what the particular thing has been that has excited the subsequent attacks, from the absence of details in the history of the case, I am unable to say.

The treatment of convulsions in children involves two distinct points: First, the treatment of the seizures, and second, the treatment of the child's general condition in the intervals, in order to prevent subsequent attacks. During the seizures, no single remedy has been in my hands so successful as the use of chloral by the rectum. To a child of this age, that is six months old, it is safe to give six grains as an initial dose, and repeat this in half an hour, and again at the end of an hour unless the attacks are controlled in the meantime. It is to be given preferably in warm milk, and we can generally count upon producing an effect in fifteen or twenty minutes after the administration of the first dose. It is often necessary to give chloroform for the first few minutes, while waiting for the effect of the chloral. Another valuable remedy in the convulsions of children, is morphia given hypodermically. There is a strong prejudice in the minds of the profession against the use of morphia in the case of young children, but its injurious effects have been owing to the overdose that has been administered rather than to the use of the drug itself. It is certainly a drug that we can ill afford to do without in this connection. One-eightieth of a grain can be safely given to a child as old as this one, and the dose repeated in half an hour if no beneficial effects are produced. It is always best in giving morphine to children, to give small doses repeatedly, rather than a single large one at once. Ice, or iced cloths should also be applied to the head, and the child kept as quiet as possible during the attack. I will say, in this connection, that I have seen very little good result secured by the commonly employed treatment of mustard baths. Harm is often done by the unnecessary disturbances of the child. If constipation has preceded the attack, or there is a history of the child having eaten any indigestible food, the colon should be irrigated in the first instance, and in the second instance, the stomach should be washed out, whatever other methods you employ, for these procedures generally allay the attack. In the interval, in ordinary cases, it is sufficient to keep the child under the influence of the bromides for several weeks, or longer, if the attacks have occurred several times. In the case of this child, you will have to do something more. In order to control this tendency to convulsive seizures, we must give prompt and immediate attention to the rickets. To this end, we will give cod liver oil and $\frac{1}{200}$ of a grain of phosphorus, three times a day, dissolved in the oil. These remedies are to be kept up for several months, the child to be taken as much as possible into the open air, and regular habits of nursing and sleep enforced.

VARICELLA.

The second patient now I present to you for diagnosis. He is five years old, and is generally well developed. We will first make an examination of his skin and afterwards get a history of his disease from the mother.

In making an examination of a cutaneous disease in a child, it is always well to strip him completely and examine his entire body. An eruption may present very peculiar features upon one part of the body so as to render a diagnosis very doubtful; while in another part it may be perfectly typical. In adults it is not always possible for the physician to do this, but there is that advantage in pædiatrics that the physician has at least, the privilege of examining the entire body of the patient.

As the child's body is now completely exposed to view, you notice it is covered with

a sparsely scattered eruption. It is discrete everywhere, a little more abundant over the shoulders and trunk than over the extremities, and rather less upon the face, than upon the body. In some parts we see vesicles, in others, papules, and in others still, you will notice that vesicles have dried and form small crusts with a slightly depressed centre. In other parts, there are found simply macules. All these varieties are found in pretty close proximity to one another. There has been considerable itching of the skin, as is evident by the amount of irritation we see about some of the older spots. Nowhere do you see any of the patches coalescing.

In calling upon the members of the class to make a diagnosis of this condition, Dr. A. says scabies; Dr. B. papular eczema; Dr. C. erythema and Dr. D. varicella. The last diagnosis is certainly the most probable one. There is one point by which we can make a differential diagnosis of varicella from any of the skin affections suggested by the gentlemen of the class, and that is by an examination of the mouth of the patient. I find on looking into this child's mouth, a typical vesicle on the hard palate, and another one upon the inside of the cheek. Under these circumstances this point is enough to settle the question of diagnosis. The appearance or non-appearance of the spots in the hair is not of any special diagnostic value. One other point by which we may differentiate varicella from many other forms of eruptive fever is the great diversity of lesions seen at the same time on the patient. This is due to the fact that the eruption comes out in successive crops every two or three days. So we may have all the different stages of the disease represented in a given part of the body.

Ordinarily, varicella is so mild a disease that it scarcely needs any treatment. A diagnosis, however, is always desirable; and in this case one fact in the history is sufficient to diagnosticate it from papular eczema or scabies, viz.: that it made its appearance within the last three days. It should be remembered that varicella may be serious and even fatal. When such is the case, it is most frequently in institutions where many children are congregated, and then usually a fatal result is brought about by complications. I have on two different occasions seen a fatal result follow an attack of varicella from a complicating erysipelas developing about the pustules. Occasionally a localized gangrene is seen, forming a distinct variety of this disease known by the name of varicella gangrenosa. Nephritis has also been observed as a complication of this disease and in a few instances, bronchopneumonia. So that in institutions practically all cases of varicella should be isolated with promptitude, as the disease is of quite a contagious character, and during the period of desquamation, warm baths should be given daily to the patient, and this should be followed by inunction with carbolized vaseline, or a one per cent. ointment of ichthyol. Continued disinfection of the skin during the period of desquamation is always advisable.

SPECIMEN FROM A CASE OF CEREBRO-SPINAL MENINGITIS.

I will now pass around the class for inspection a specimen of a brain removed from a child who died two days ago of cerebro-spinal meningitis. The child was perfectly well until four days before his death when he was suddenly taken ill with a temperature which ranged from 104° F. to 105½° F., throughout the day. He vomited twice in the morning and had one large, normal stool. A physical examination failed to reveal any evidence of disease either in his throat or lungs. On the following day the temperature range was between 103° F. and 105° F., and pulse from 150-160, respiration regular, and the child showed some signs of restlessness. There was no more vomiting. During the night the patient was quite restless and on the morning of the following day he developed marked signs of nervous irritability. He bit his fingers and rolled about restlessly in his crib. Muscular twitchings developed at the extremities during the afternoon, and there were noticeable signs of general hyperæsthesia. The pupils were dilated and responded imperfectly to light, but there was no rigidity or any evidence of paralysis. The child looked pale, occasionally uttered low screams and prostration gradually began to increase.

On the evening of the following day some rigidity of the muscles of the neck were for the first time noticed, with slight rigidity of the extremities. The abdomen was rounded but soft and natural. The pulse rose to 200, was very feeble, and almost imperceptible at the wrist. During the night he passed from a half-drowsy state into a condition of semicoma. On the morning of the next day he was comatose with the right hand remaining quiet and the left hand constantly moving. Twitchings of the right hand and

face were noticeable at this time and death took place at 11 A. M. that day, the temperature being $105\frac{6}{10}°$ a few hours before that event.

No cause could be assigned for this illness save that the child had had a discharge from both ears, which, however, had ceased six weeks previous to his death. On further inquiry it was found out that the child had sustained a fall $2\frac{1}{2}$ weeks previous to his fatal illness, but this was followed by no important symptom at the time. It is doubtful if either of these factors, the fall or the otorrhœa, played any part in bringing about the death of this child.

The autopsy showed all the organs essentially normal, except the brain and spinal cord. The anterior half of the brain, you will see, is covered with a thick layer of lymph and pus, giving to it a yellowish-green hue, and concealing the normal brain substance. This is found in greatest abundance over the convexity. At the base of the brain it follows the line of the Sylvian fissures, and in the posterior half, this exudate is seen in patches, but nowhere does it cover a continuous surface. It is generally found distributed along the course of the blood vessels. There are no tubercles present, and the ventricles are not distended. There is no softening of the cerebral substance.

The cord is normal, except at its lower portion, where a small collection of pus was found. There is no lymph coating the membranes of the cord.

The diagnosis of this case was exceedingly obscure until the night before the death of the child. Up to that time he presented simply the symptoms of an acute febrile illness, with very high temperature and marked prostration. Please note in the history the absence of the common and classical symptoms of meningitis, viz.: persisting vomiting, constipation, retraction of the abdomen, photophobia and early opisthotinos. It is extremely difficult in these abrupt cases of meningitis to make a diagnosis. They much more resemble cases of acute pneumonia than those of meningitis. It is only by careful and repeated examination of the lungs in this case that pneumonia was excluded.

A great deal of light has been thrown on the etiology of the cerebro-spinal meningitis within the past few years. Many of these cases of meningitis are found to depend upon the pneumo-coccus of Fraenkel. This germ has been found more frequently than any other in this particular disease. In a case of my own, recently studied bacteriologically by Dr. M. Prudden, of this city, cultures of pneumo-coccus were found in the exudate. This case is the more interesting from the fact that the symptoms were largely pulmonary.

NEURALGIA SECONDARY TO LA GRIPPE—CHRONIC BRONCHITIS—PLEURISY WITH EFFUSION.

BY JOSEPH M. PATTON, M. D.,
PROFESSOR OF CLINICAL MEDICINE IN THE CHICAGO POLYCLINIC, CHICAGO, ILLINOIS.

Gentlemen:—This lady came to the clinic about a week ago complaining of neuralgia of about two weeks' duration. Now, we know that the ordinary person terms everything that is painful neuralgia, but when she describes the pain by running the finger down the line of the sternomastoid, down the anterior border of the trapezius, over the deltoid and over the extensor muscles of the forearm, of course we begin to doubt its being neuralgia. Neuralgia is an acute pain which is located along the course of one of the nerves. If it is neuralgia you can determine the exact nerve to which the trouble belongs. For instance, if an individual has neuralgia of one of the branches of the 5th nerve, it will be located over the portion supplied by that nerve. If it is the first branch you will have pain over the temple and around the ear, over the top of the head; if it is of the second branch of the trigeminus you will have pain over the malar bone, down along the affected side of the nose, and perhaps extending down to the jaw. If it is the third branch you will have pain in the jaw radiating down under the chin. If there be neuralgia of the cervical nerves you will have pain radiating from the back of the neck around towards the front or down towards the shoulder; and if it is the intercostal nerves, or the nerves of the arm, you will have pain following the course supplied by these nerves. If the neuralgia is due to an affection of the nerve, an inflammatory condition of the nerve, you will generally be able to locate some sore spot. In neuralgia of the second branch of the 5th, if it is due to an inflammatory condition of the nerve, you will find a sore spot in front of the ear or immediately below the eye or just below the center of the malar prominence. If you touch these branches of nerves you will have severe pain; there will be some tender spot; you may have just as severe pain in one of these nerves without any sore spot whatever. When you place your finger in

the region of the affected spot there is soreness, which extends along the muscles of the neck and shoulder. She complains of severe pain when we put the cervical muscles on the stretch. It has the appearance of a rheumatic affection of the muscles rather than of neuralgia. She tells us that some two or three weeks ago she had an attack of the grip, and after recovering in a measure from that she became afflicted with this pain. Now, neuralgias and rheumatic pains in the muscles and tendons are often secondary consequences of the grip. I have seen two or three most severe neuralgias secondary to attacks of the grip this winter. They are not what you might call true neuralgias, that is, they are not due to an inflammatory condition of the nerves; they are apparently rheumatic in character, and are relieved by rheumatic remedies. One case was under my care two or three weeks ago, following a moderately severe attack of the grip. It was a case of neuralgia of the second branch of the 5th nerve, with no tender spots especially. The face was sore over the nervous foramina and was entirely unrelieved by any of the neuralgic remedies.

All those remedies which are said to be efficacious in neuralgias of the 5th nerve, such as gelsemium, aconite, aconitine, cimicifuga, the ordinary neuralgic pills—all of those remedies from which you would expect effect in neuralgias of the 5th nerve, were entirely ineffectual. You will find that the pain is relieved temporarily, but not sufficiently so to do any good. The pain in this case was relieved by salicylate of soda administered in large doses, twenty grains every two hours. The pain disappeared promptly, and under its continued use for two or three days, failed to return. There were no unpleasant effects from its use. Ordinarily, such large doses of salicylate of soda will cause unpleasant effects in most patients, such as dizziness, tinnitus aurium, headache.

Now, the point to bear in mind in these neuralgic and rheumatic pains that result from the grip, is that they are not, as a rule, true neuralgias, they do not result from inflammatory conditions of the nerve, but are systemic conditions, and are best relieved by some anti-rheumatic remedies. This woman has been taking bromide of quinine and phenacetine, two grains of quinine with five or six grains of phenacetine, every two or three hours. While that relieves the pain while she takes it, the soreness of the muscles is much better, but still persists.

In using these synthetical remedies for pains, as a rule, if you do not get response to the administration of them within a few hours it is best not to expect any result from them; if they do not promptly relieve the symptoms they fail, and if they afford relief at all it is within a few hours. As this soreness still persists, I think this patient will do better on salicylates than anti-rheumatic remedies. I would prescribe for her to-day, ten grains of the salicylate of soda, every two or three hours, according to the way in which her stomach will bear it. In some people it is an irritating medicine to administer as far as the stomach is concerned, and you have to be careful, especially in women, and give it largely diluted in water. I expect that will relieve her trouble better than anything else.

This lady is another victim of the current affliction. She had the grip about two or three weeks ago—a slight attack of it, and since that time has been complaining of weakness. She feels almost too weak to go about—no ambition. She also has some pain in her limbs and arms and in the back of her neck. You will notice in regard to the pains that are complained of in these attacks of the grip, barring the headache, that they are, as a rule, confined to the tendons of the cervical region and the lumbar region, with some pains in the limbs. These pains are sometimes very severe in the cervical region, and also in the lumbar region, with no special stiffness of the muscles. Her trouble now is probably the weakness that is complained of. It is somewhat surprising the amount of physical weakness which will follow a comparatively slight attack of the grip. This year the name influenza would hardly seem to apply to the disease, as there are very few cases that have exhibited any marked trouble with the mucous membranes; it is not the characteristic coryza or sneezing, or the suffused condition of the eyes or pharynx that is complained of, nor the mucous membrane of the larynx, and there is not so much bronchial inflammation in the start, though that may follow as a secondary matter. This year the symptoms of influenza are entirely wanting, and the trouble consists generally in high temperature, great weakness and pain. The weakness which follows these attacks is not at all consistent with the amount of temperature or with the length of the attack. I have seen several cases where the temperature did not go above 101°, and where there was very little pain, and yet the secondary exhaustion following the attack would last from one to three weeks. Again, you see cases with a temperature of 103° or 104° with

not very much pain, which seem to be well in a few days after the temperature goes down, so that the exhaustive effects depend upon the condition of the system of the patient, and not on the height of temperature or severity of attack.

The administration of remedies for the acute stage of this trouble may have something to do with the exhaustion which follows. It is fashionable to give antipyrine, acetanilid, phenacetine, antiferbrin with, or without quinine, both because that is the fashion of the day, and because they are very efficient remedies for reducing fever and pain; at the same time they leave a depressing effect. Any of you who have administered antipyrine in marked doses in typhoid fever or pneumonia, or any of the acute exhaustive diseases, will have noticed that you get a more depressing effect from its prolonged use, than in those cases in which these drugs are not used. These patients will take quinine for three or four days, and if they do not get much better they will go to a physician, and he gives them as much antipyrine or acetanilid as they will stand, and by the time they are beginning to get well they complain of great exhaustion due, perhaps in part, to the administration of these remedies; at any rate, there seems to be a great deal more exhaustion following the grip this year than I ever noticed before.

Another marked feature of the disease this year, is the tendency to bowel trouble—catarrhal inflammation of the bowels. As a rule there is not much difficulty with the stomach; the trouble seems to be with the intestines. The diarrhœa will begin with the active symptom of the disease, or will follow as the patient begins to get better; it is accompanied by considerable fermentation, a good deal of flatulence. The passages are frequent, thin, slightly greenish as a rule, showing evidences of imperfect digestion. That has been the case also with pneumonia. I have hardly seen a case of pneumonia this winter that has not been accompanied by diarrhœa—even the asthenic cases of pneumonia all have it, and in the other cases which occurred in people who were weak and feeble, they were also afflicted with it. For instance, a woman was under my care a short time ago who had had chronic bronchitis for years; she was very much run down in health; she had a croupous pneumonia of one lung, which got along fairly well, but the attack in her case was accompanied by diarrhœa during the course of the trouble. Another case, a strong, active young man of 20, with double pneumonia, respiration 45, and pulse 140, temperature 104°, a very severe one, also developed diarrhœa about the time that the temperature began to drop. And so it ran through all the cases. I lost a case of pneumonia this morning in a young man of 27, where the trouble began as a gastritis, which I succeeded in relieving, when pleuro-pneumonia developed with an active diarrhœa all the time. This diarrhœa is not dependent upon what you feed the patient. I have kept them on an exclusive milk diet. I have fed them on beef peptonoids and beef extracts, and on broths; I tried every manner of diet, and it makes no difference. It seems to me some atmospheric condition.

As regards treating the exhaustion which follows attacks of the grip, of course much depends on the patient, the character of the attack, and the amount of food which they are able to take. They should be put on tonic treatment, and among the best things to feed these patients with are some of the tonic wines. Coca wine or Tokio wine, which is a good deal used just now, is very beneficial. The coca wine of Mariana & Co. is a nice preparation—one which I have used a good deal in these cases, one glassful two or three times a day. They respond to it nicely. It has a tonic action on the mucous membrane of the throat and larynx where there is troublesome cough, or hoarseness of the voice. They should be fed on light diet, that is a diet from which the starches, sugars and fats are excluded, so that you will not have much transformation of sugar into glycogen, and therefore there is not much chance for fermentation. For the tendency to fermentation and diarrhœa the best remedies are those which prevent intestinal fermentation, intestinal antiseptics. The old remedies, bismuth, or dilute mineral acids are good. It is more fashionable now to use salol, napthol, napthaline, thymic acid, or some such preparations. Salol is a nice remedy, and should be given in 5-grain doses in the form of a sugar coated pill, one every three or four hours. You can use napthol and napthaline if you so desire Where there is fermentation in the stomach, one of the best remedies is a grain, or a grain and a half of thymic acid, with five grains of charcoal in a capsule; it relieves fermentation nicely.

This patient complains principally now of flatulence, and not so much of diarrhœa. She says her bowels are not loose at the present time, but that the flatulence is the only trouble that bothers her. I would put her

on one of these remedies—salol, for instance, with one of tonic wine, and expect her to regain strength quite rapidly.

CHRONIC BRONCHITIS.

This lady comes to us from the throat clinic. She complains of hoarseness. This hoarseness she has had for two or three years, mostly in winter. Professor Brown has referred her to us for examination of her chest in order to determine whether there is any condition there which would add to the permanency of this hoarseness. She says she has some cough nearly always in winter, and that it bothers her more in the evening than at any other time. That fact which she states of her own accord, that the cough is more troublesome at night than in the morning, would probably exclude the stomach as a cause of the cough or laryngeal irritation, for the reason that coughs which arise from the stomach, as a rule, are more troublesome in the morning than at any other time. If the reflex trouble of the stomach is the cause you will find the coughs are more troublesome; immediately after getting out of bed, they cough a long time until they raise a little mucus, then perhaps they will not cough but once or twice during the day to amount to anything. That is not only characteristic of stomach cough, but it is characteristic of trouble with the stomach in any chronic cough. Where you find the coughing spell is in the morning you may look at once for some trouble with the stomach. She says her cough is worse in cold, damp weather, sufficiently so to make her quite short of breath at times.

Expansion of the lungs is good; vocal fremitus is unchanged, and the percussion note is unchanged. The only thing I find wrong with her lungs is a slight harshness about the breathing over the upper portion of the lungs in front, produced by a little chronic inflammatory condition of the bronchial lining. Occasionally through her lungs during the first one or two deep inspirations you find solitary râles which disappear after deep inspirations, showing that there is a little adhesive mucus which is displaced by deep breathing. This may have something to do with her hoarseness, as the bronchial coughs which are worse in winter and during damp weather, which clear up during dry weather, are due to a little swelling of the mucous membrane with increased secretion of mucus, nd are very apt to cause congestion of the vocal cords or of the larynx from the constant coughing and hacking which they produce, and you frequently see these conditions of the larynx clear up after having cured the condition existing in the bronchial tubes.

Now, for the relief of that condition. You want something slightly expectorant with an alterative, especially in old women. One of the best combinations is five to ten grains of iodide of potash with two or three drops of tincture of belladonna, and about the twelfth of a grain of tartarized antimony. In children and young people, one of the best remedies is the syrup of hydriodic acid which contains a certain percentage of free iodine, and is a most excellent way to give iodine. It is very palatable. I have seen localized bronchitis, both in children and in adults, which would resist all kinds of cough mixtures and all kinds of tonics, clear up promptly after the administration of a little iodine in this way. It is especially valuable in those chronic coughs which follow whooping cough and measles in children, and it is an excellent remedy for these conditions. To this woman I should give five grains of iodide of potash, or you may give iodide of soda, either one, I prefer iodide of potash in this case, with a little tartarized antimony, and no belladonna on account of the tendency to an inflammatory condition of her throat, because if she got enough to affect the mucous membrane at all, it would make her throat and larynx dry. She would cough more and experience more difficulty with her throat, so that we will leave the belladonna out.

PLEURISY WITH EFFUSION.

This boy, aged 15, we aspirated last week. I brought him here to-day for you to see whether there is any change in his condition or not. He says he feels much better in every way. Although we removed three quarts of fluid from him at that time, there were fully three pints left. You remember that his heart was much displaced, almost to the right nipple and the lung very much compressed. As to the amount of fluid which you should remove in these cases, it depends a good deal on the nature of the effusion and on the case. Where the chest has filled rapidly, and where there is a great deal of effusion, especially in young subjects, I see no objection to removing at least three-fourths of what is there in the chest or more if you can do so without causing any dyspnœa. This boy, after he got off the table last week, as soon as he began to move around, began to cough, which was quite severe, hacking, and irritating, and was forced to lie down and rest until his lung

had accommodated itself to the greater amount of room before he could move around. Where the patients begin to cough or complain of some constricting pain in the side while withdrawing the fluid it is about time to stop.

I want you to look at the difference in the spine. You remember how much lateral curvature there was of the spine last week. That is nearly straightened out now, and it was supposed to be due to the weight of the fluid in the left side, which caused it to gravitate in that direction. You notice a little prominence on the left side of the sternum, at the costo-cartilaginous junction, it has not disappeared, and that is probably due, as we had previously supposed, to some bending of the junction of the ribs and the cartilage from pressure, and was doubtless there from infancy,—one of the slight forms of what is called pigeon breast—which is due to some interference with the respiratory conditions which produce pressure on the ribs at the time when the cartilages are soft and bend very easily. You will find these conditions developing in children who are the subjects of enlarged tonsils for a long time and have difficulty in breathing; you will find them developing a prominence along the sternum due to pushing out of the ribs, from increased pressure in the lungs made by the efforts at respiration—efforts to get the air out of the lungs, caused by the small amount of room in the throat where the tonsils are quite large. You will find that if the tonsils are removed in the early stages of these slight deformities, they will generally disappear, or at least will not grow worse.

The next thing we notice is that there is absence of pulsation in the right mammary region, where it existed last week, and that pulsation has moved over to the left of the sternum, and has almost regained the natural area of cardiac pulsation. We can now feel the action of the heart in the natural area. You notice there is some motion of that side, it is not as good as it ought to be, but it is better than it was. The percussion note is vesicular in quality down as far as the 7th rib, from that point it is more or less flat. You can hear the respiratory murmur all over the left side down to the present line of flatness and behind below the angle of the scapula. You may occasionally, when he takes a deep inspiration, hear the rubbing of the pleural surfaces over each other at the end of each inspiration—a dry, grating sound. There is still a slight amount of fluid in the left cavity.

As to the likelihood of these cases filling up again, in a case like this, a young boy who has developed that amount of fluid within a comparatively short space of time, if the fluid is taken out inside of a week or so of its development, as a rule there is little danger of the pleura refilling; but if the condition be left alone for several weeks, and the patient is very much run down in strength, you are apt to have the pleura refill again. This is especially likely in old people. In patients who are 60, 70, or 75 years old you will find pleurisy develops quite rapidly, and even though it may be removed if there is marked compression of the lung, you will find that such cavities will fill up again, so that you are apt to tap them two or three times. But as a rule after two or three tappings they cease to refill, and you have no further trouble with them. It is probable that the small amount of fluid which remains at the end of a week in the left side of this boy will not compromise the lower portion of the lung or the pleural surface before it is absorbed, so that it is hardly worth while to attempt to withdraw it; the expansion of the lung has sufficiently increased and circulation is good enough to take it up without much difficulty. I expect at the end of two weeks to be able to get a dry friction sound clear to the bottom of the lung; this sound will disappear as the pleura becomes healed, and there will probably remain a slight thickening of the pleura which will probably do him little or no injury.

COMMUNICATIONS.

THE RELATION OF CONCUSSION OF THE BRAIN AND SPINAL CORD TO INFLAMMATORY AND OTHER MORBID CONDITIONS IN THESE ORGANS.

BY B. A. WATSON, A. M., M. D.,

CONSULTING SURGEON TO THE BAYONNE HOSPITAL, SURGEON TO JERSEY CITY HOSPITAL, ETC.

It is certainly apparent to all members of the medical profession that brain and spinal surgery has received during the last quarter of this century an unusual and likewise unprecedented amount of attention. It is likewise equally apparent that great progress has been made by those who are devoted to this branch of surgery; it therefore becomes

highly necessary, that he, who is about to enter this field of medical literature, should first discover some dark spot or disputed question, on which he thinks he may possibly throw a few rays of scientific light. The traumatisms of the brain and its membranes have been more fully studied than those of the spinal cord. Undoubtedly this may be accounted for in part by the fact, that the first-mentioned organ is much more frequently the seat of these lesions than the latter.

I shall therefore direct the greater portion of my attention especially to any lesions following traumatic injuries of the spinal cord and its membranes.

It seems necessary to call attention to certain errors as a preliminary to the consideration of our first inquiry.

One of the most important of these has been expressed by Mr. Erichsen, in the following language: [1] "The consideration of the effects that may be produced on the spinal cord by *slight blows*, whether applied to the back or to a distant part of the body, is not altogether a matter of modern surgical study arising from the prevalence of railway accidents, but had, long antecedent to the introduction of modern means of locomotion, arrested the attention of observant practitioners." Since the above statement was made it has been clearly demonstrated to be erroneous by anatomical and experimental investigations. The anatomical studies have shown that the spinal cord is the best protected organ in the body, and experimentation has fully confirmed this position. The experiments which I made on dogs—the total number being 141—which were arranged and conducted for the especial purpose of producing concussive lesion in the spinal cord and its membranes fully convinced me that it required *a very severe blow*, which must even be delivered on certain limited areas of the body, in order to accomplish this object. I am likewise satisfied that this conclusion must neccessarily follow a careful study of my report entitled: "An Experimental Study of Lesions Arising from Severe Concussions."[2]

It should be further stated that the lesions produced in the spinal cord and its membranes are rarely apparent to the unaided eye, but were readily revealed under the microscope. This statement, however, does not apply to those cases in which there were either fractures or dislocations involving the vertebræ; since the lesions here were comparatively coarse.

The statement that a rupture of the spinal membrane has occurred, or that there has been a gross hæmorrhage into the substance of the spinal cord, or between the cord and its membranes, is certainly not entitled to credence unless coupled with the acknowledgment of either a fracture or dislocation of a vertebra. This statement is based on my examination of the lesions found in the spinal cord and its membranes, and I am so thoroughly convinced on this point, that I feel warranted in making this positive statement.

The so-called "railway spine" includes true concussion arising from blows, falls, gun-shot wounds, lightning strokes, electric shocks, etc., likewise contusions on the back, sudden flexions of the spinal column, sprains, wrenches and twists. Dr. John A. Lidell says, in discussing the consecutive effects of some of these injuries that: [1] "Among the remote effects of *sprains, wrenches and twists* of the spinal column, are chronic *inflammation of the vertebral joints* that are implicated, which is often suppurative in character, *destruction of the articular cartilages* and the *intervertebral substances* that are involved, and *caries* or *necrosis* of the adjoining vertebral bodies. In such cases, the destructive process begins more frequently at the junction of the vertebræ with the intervertebral substances than in the intervertebral substances or vertebræ themselves, because, as Mr. Hilton has pointed out, we know that in accidents, at least as far as we have been able to discover, "the most frequent lesion in injury to the spine is a partial severance of the vertebræ from the intervertebral substance."

A number of illustrative examples have already been presented, and inasmuch as this topic has already been pretty thoroughly discussed, no apparent need exists for presenting any additional instances of the same sort. I will, however, take space, to present a very instructive case, in which there simultaneously occurred lumbo-sacral abscess and suppurative spinal meningitis, in consequence of a blow on the spinal column:

The following abstract made from the report of the history of this case supplies the essential points: A healthy lad, of fifteen years, was struck by his playmate on the back with the fist. He thought little of it

[1] On Concussion of the Spine. A New and Revised Edition. London, Longmans, Green & Co., 1882.

[2] P. Blakiston, Son & Co., Philadelphia, 1890.

[1] International Encyclopædia of Surgery, Vol. IV, p. 870 et. seq. Edited by John Ashurst, Jr., M. D., Wm. Wood & Co., New York, 1884.

at the time, but was admitted to Guy's Hospital nine days afterwards; was treated with leeches and somewhat recovered, but the pain soon returned and fever ensued. "An abscess formed on the right side of the sacrum, which was opened, and continued to discharge, the flow of pus being increased by pressure on the abdomen. He continued to get worse daily, having much irritative fever and severe pain in the back. During the last week of his life he was exceedingly restless, and often delirious; and he complained of pain in all parts of his body, but particularly in the extremities. On one or two occasions he had loss of power over the bladder and rectum, but had no other symptoms of parapelgia, and could move freely in bed." He died twenty-two days after the casualty,

Autopsy:—An aperture in the integuments at the right side of the sacrum led into a very extensive abscess, external to the peritoneum, which occupied the forepart of the sacrum behind the rectum, and external to the ilia on both sides behind the psoas muscles. The bones were exposed but not diseased. Although the abscess had discharged externally on the right, it was most extensive on the left. It had burrowed up to the left side of the last lumbar vertebra and the sacrovertebral foramen into the spinal canal. When the theca was opened, it was found to contain a quantity of greenish pus, spread over its inner surface and over the cord itself. The spinal dura mater (theca) at the point indicated, was softened and destroyed, and the cauda equina was lying bathed in pus which filled the sacral canal. The membranes of the cord were inflamed throughout the whole extent, and there was purulent effusion as high as the dorsal region. The spinal dura mater was thickened, and its inner surface had lost its smoothness and transparency, and was of a dull green color. Pus could be squeezed out from beneath the visceral arachnoid in considerable quantity. The spinal cord itself was firm, and the microscope revealed no morbid condition in its substance. On opening the cranium, cases of acute arachnitis were found over the whole surface of the brain, greenish-colored lymph being effused into the sub-arachnoid tissue, especially at the base. The inner surface of the dura mater, around the foramen magnum and on the adjacent part of the occipital fossa, was of a greenish color, from lymph effused upon it. Bronchial tubes filled with tenacious mucus. Lumbar and bronchial glands slightly enlarged. All other organs entirely healthy.

The purulent infiltration of the spinal meninges which was observed in this case, occurring coincidently with the formation of a lumbo-sacral abscess, but without the production of paralysis, could scarcely have happened unless the sacrovertebral articulation had previously been opened, both externally and internally, but disease of the articulation itself in such a manner as to allow the products of inflammatory action to flow freely out of, as well as into, the spinal canal. Otherwise, the suppurative meningitis would pretty certainly have caused paralysis by compressing the spinal cord with its inflammatory products.

The clinical history of this lad's case, interpreted by the post-mortem appearances, appears to have been as follows: The blow on the back wrenched the sacro-vertebral articulation and caused a suppurative inflammation to be lighted up therein, particularly on the left side, and in consequence of this, purulent matter escaped in an outward direction, and led to the formation of an immense lumbo-sacral abscess; it likewise escaped in an inward direction, and caused the theca vertebralis to become softened and perforated, and extensively destroyed, and a diffuse suppurative inflammation which extended upward to the brain, to be kindled in the spinal arachnoid. It has been aptly said that "in all science, error precedes the truth, and it is better it should be first than last."[1] I have cited the case reported by Dr. Lidell, with all its details, in order that I might bring forward some of the results of my observations, made during my recent experiments, which afford a correct and rational explanation of the condition revealed by that post-mortem examination. There will be found in the report of my experiments, eleven cases, in which there was rupture of the ligaments of the sacro-lumbar articulation. There were marked pathological changes in the organs and tissues within the pelvic and abdominal cavities in six of these cases, which were immediately connected with the rupture of the ligaments of the sacro-lumbar articulation. Let me here present the following abstracts from post-mortem examinations for the purpose of giving a correct idea of the character of the lesions:[2] "Autopsy.—This examination re-

[1] Walpole.

[2] An Experimental Study of Lesions Arising from Severe Concussions, by B. A. Watson, A. M., M. D., p. 32, Exp. 4.

vealed, a rupture of the ligaments between the last lumbar and the first sacral vertebræ, deep and extensive ecchymoses over the entire post-sacral and right lumbar regions. A profuse extravasation of blood into the abdominal cavity, marked engorgement of the kidneys. Brain apparently normal, slight increase of the cerebro-spinal fluid in the cavities, and the cord was congested, to the middle of the dorsal region."

"Autopsy.[1]—This examination revealed the following lesions: Both kidneys congested; ecchymosis in the connective tissue covering the anterior surface of the last lumbar and the upper sacral vertebræ. The brain and spinal cord apparently hyperæmic. The removal of the integument over the sacral and lumbar regions showed an ecchymotic condition of the muscles. There had been a rupture of ligaments between the last lumbar and upper sacral vertebræ."

"Autopsy.[2]—This examination revealed the following lesions: Both kidneys congested; bladder distended with urine; extensive ecchymoses in the lumbar and pelvic regions involving psoas muscles; brain perfectly normal; the spinal cord was hyperæmic downward from the lumbar enlargement, including a portion of the cauda equina; rupture of the ligaments between the last lumbar and the first sacral vertebræ."

The essential point which Dr. Liddell has overlooked in his comments on the case which he has reported, are the pathological conditions of the organs and tissues within the pelvic and abdominal cavities. It was the *existence of these lesions which gave rise to the inflammation and suppuration* within these cavities. The post-mortem examination of Dr. Lidell's case sufficiently demonstrates this position. Dr. Lidell says:[3] "The blow on the back wrenched the sacro-vertebral articulation, and caused a suppurative inflammation to be started up there." The autopsy in the case fails to show that there is any erosion of the bones or cartilage within this articulation, and its history reveals the fact, that it was only immediately before death that there was the slightest indication of paraplegia. It is therefore certain that the wrench which he mentions consisted in producing a rupture of the ligaments of the sacro-lumbar articulation and likewise, as very frequently happens in those cases, some pathological lesions within the pelvic and abdominal cavities. The simple wrenching of any joint in a healthy subject—unattended with pathological lesions, has been amply shown to be a comparatively trivial injury, which does not lead to serious inflammatory complications or death.

The one hundred and forty-one experiments, which I made on animals, does not afford a *single example* which justifies the conclusion that injuries to the vertebral articulations are a whit more serious than those produced in the carpal and tarsal articulations; and, consequently, analogous reasonings may be here employed with entire propriety. We can not pass over the history of Dr. Lidell's case without pointing out a glaring absurdity, which may possibly have had its origin in carelessness. In this report, we are informed that a healthy boy, aged fifteen, "while playing with another lad, received a blow on the back with the fist," and in the absence of any additional statement bearing on this injury, we are left to infer that the pathological changes and even the death of the patient were directly caused by this blow.[1]

He who has examined the anatomical structure of the spinal column will readily perceive the absurdity of this statement. The blow inflicted was entirely inadequate to the production of the results which followed, unless there has been omitted from this report the most important factor in the history of this case. It is true that the force of the blow might cause the lad to fall—and if at this point, the history of the case showed that the boy fell across a bar, raised a few feet from the ground, in such a manner that his feet remained on one side, while his head was on the other, then the very important factor of leverage having been added, which would result under these circumstances in the production of a sudden flexion of the spinal column, would certainly bring within the limits of possibility the occurrence of the injuries which are reported in the autopsy.

It is scarcely necessary to mention the fact, that nearly all the injuries grouped together under the unfortunate cognomen of "railway spine"—so far as their remote effects are concerned—take their origin, either directly or indirectly in inflammatory processes. Consequently the consideration of the following queries assume importance:

1. Do inflammatory and other morbid changes take their origin in traumatic injuries of the spinal cord and its membranes

[1] Ib., p. 35, Exp. 10.

[2] Ib., p. 40, Exp. 24.

[3] Previously cited.

[1] Previously cited.

as frequently as the writings of Mr. Erichsen imply?

2. Do inflammatory and other morbid changes ever arise from traumatic injuries which are entirely uncomplicated by immediate symptoms?

3. How soon are the inflammatory and other morbid changes developed after the receipt of traumatic injuries in the cord, etc.?

In our consideration of the first question it is scarcely necessary to give a negative reply to those who have perused the writings of Mr. Erichsen on this subject; since they have already reached this conclusion. Furthermore, the mere assumption that serious results frequently arise from wholly unimportant injuries is not sustained by clinical observations or experimental investigations. However, Mr. Erichsen, in writing of those cases in which the patient has received no blow or injury upon the head or spine, but in which the whole system has received a severe shake or shock, in consequence of which an immediate lesion, probably of a molecular character, is sustained by the spinal chord and disease of an inflammatory character, or of a disorganizing nature is developed in it, the inflammatory action eventually creeping up to the membranes of the brain, says that the cases[1] "although necessarily more frequent in railway than in other injuries, do occasionally occur as a consequence of ordinary accidents." A perusal of Mr. Erichsen's writings has completely failed to convince me that he has supplied any basis for the support of the opinion advanced in the above statement.

In order, to demonstrate the correctness of this opinion which conflicts with all positive knowledge we possess on this subject—and which can not be supported by analogous reasoning—he should clearly establish the following facts, viz.:

(1) *That no disease of the brain or spinal chord existed at the time of the occurrence of the alleged accident.* (2) *That the consecutive inflammation did arise from the traumatism, and was not due, in part, or wholly, to a vitiated constitution.*

This evidence is entirely wanting; and, consequently we must maintain that Mr. Erichsen's statement should be excluded in cases of medico-legal evidence.

We have now devoted our attention to the consideration of the material points involved in our first query, but it would seem proper in this connection to give some additional thought to the consecutive results of concussive accidents.

Mr. Erichsen says[1]: "Whatever may be the nature of the primary change that is produced in the spinal cord by a concussion, the secondary effects are clearly of an inflammatory character, and identical with those dependent on chronic meningitis of the cord and sub-acute myelitis." The term concussion as employed in the above quotation evidently refers only to traumatism of the spinal cord and its membranes, but elsewhere the same author in speaking of sprains, twists and wrenches of the spinal column, says[2]: "It is important to bear in mind that the vertebral column is more apt to suffer in these strains of the spine than in the other forms of injury that we are discussing, and that in serious cases the full force of the mischief appears to be expanded in the spine itself independently of its contents which escape uninjured." The views expressed by Mr. Herbert Page on this subject are as follows[3]: "Happily, there is no doubt of the exceeding rarity of spinal meningitis, as an immediate result of localized injury to the vertebral column; and I know of no case in which meningeal inflammation has been caused by injury of some part of the body remote from the spine." The experimental study of concussion of the spinal cord has satisfied me on the following points: (1) True concussion of the spinal cord from blows, falls, lightning strokes, etc., is an exceedingly rare occurrence. (2) Secondary results, such as inflammation, suppuration, etc., very seldom follow the traumatism, owing to the fact, that the punctate hæmorrhages, etc., are generally widely diffused in various parts of the spinal cord, while the pathological lesions are so slight as not to supply inflammatoru foci. However, the danger arising from a true concussion of the spinal cord produced by gun-shot injuries, the lodgment of a musket or rifle ball in the spinal column is attended with much more danger from consecutive inflammation, etc., than those traumatisms which have been previously mentioned because of the following peculiarities: (1) The pathological lesions are more concentrated—resembling in this respect the ecchymoses arising from a concentrated contusion. (2) The lodgment of a ball in the spinal column is very liable to

[1] On Concussion of the Spine, Nervous Shock, etc., p. 95. New York. Wm. Wood & Co. 1875.

[1] Ib. p., 157.
[2] Ib. p., 128.
[3] Railway Injuries, p. 21. Philadelphia. P. Blakiston, Son & Co. 1891.

give rise to a septic inflammation, pus formation, diseased condition of bone, extention of the inflammatory products to the spinal membranes, and even the cord itself. It must be universally admitted, that gun-shot wounds, fractures and dislocations involving the spinal column are very serious traumatisms, frequently producing death immediately, or within a few hours. Even when this result does not follow, the danger is very great from the consecutive sequelæ.

Let us now take up the consideration of the second query. "Do inflammatory and other morbid changes ever arise from traumatic injuries which are entirely unaccompanied by immediate symptoms?" The conclusions reached by a careful analysis of the above question must depend to some extent on the interpretation which we give to this query. The fact must be admitted that it is not only possible for a patient to receive, under certain circumstances, severe traumatic injuries of which he remains a longer or shorter period wholly unconscious, but that these occurrences are by no means very rare. I can now recall a number of instances of this character occurring to officers and soldiers during the excitement of battle, while I was serving with the army. It also occasionally happens that drunkenness dulls the sensibilities in certain cases to such an extent as to render the patient oblivious to an injury, which he may have received, while the same condition will more or less embarrass, and sometimes even deceive, the surgeon who is attempting to make an examination. These statements possess only an indirect bearing on the question under consideration. The question relates to the immediate existence of symptoms and not to the observance of the same. A critical examination of this question in the same direction indicated in the above sentences, brings us to the following query: "Are results ever produced without causes?"—*i. e.*, "Do inflammatory and other morbid changes ever arise from traumatic injuries, which have failed to produce any lesions?" My experimental studies of the lesions of the cerebro-spinal axis have clearly demonstrated the fact, that pathological changes are occasionally produced in this centre—some of which are even apparent to the unaided eye—while others required the aid of the microscope; but which were not followed by any symptom indicative of these lesions during the life of the animal. The question will now be naturally asked with reference to these cases: Would they not have developed inflammatory changes at a later period? I have not before me the data which would justify me in positively asserting that a result was absolutely impossible; but I can aver that, in all these experiments—one hundred and forty-one—there is not a single case which warrants giving an affirmative answer. Surgical observations and analogous reasoning fully support the results obtained by our experimental research, not only with reference to the brain and spinal cord, but likewise in other organs of the body. Mr. Erichsen says in his recent work, "On Concussion of the Spine[1]": "There is a continuous chain of broken ill health, between the time of the occurrence of the accident and the development of the more serious symptoms. It is this that enables the surgeon to connect the two in the relation of cause and effect. This is not peculiar to railway injuries, but occurs in all cases of progressive paralysis after spinal concussion." It would appear from this quotation that Mr. Erichsen fully concurs with us in the opinion, that the production of a traumatic pathological lesion is always indicated by immediate symptoms when the degree of injury has been sufficient to entitle it to our consideration. Observation has taught us that the existence of a pathological lesion affords insufficient proof that this injury will be followed by inflammation or other morbid changes. In fact, every surgeon can recall to mind cases of severe traumatic injuries of the brain in which there were extensive larcerations or contusions of this organ; but, in which the secondary changes were entirely absent or very slight.

The same remark may also be made in regard to gross injuries in other parts; since the same general physiological and pathological principles prevail in the cerebro-spinal axis as in the other organs of the body. It is therefore entirely proper to introduce in connection with discussions of injuries of the cerebro-spinal axis, in many cases analogous reasoning drawn from studies and observations made in other parts of the body. It must be admitted as a general rule in surgery, that the more extensive and the more destructive the primary traumatism, the greater will be the danger from secondary disorganizing processes. Does it not therefore seem absurd to attribute to a single punctate hæmorrhage or even a half dozen of these little pathological lesions the

[1] A new and Revised Edition, p. 158. London, Longmans, Green & Co., 1882.

power of exciting a disorganizing process in a healthy spinal cord which may ultimately produce the death of the patient?

Is there a single well authenticated case in which such a result has followed from such a cause?

Let us now proceed to the consideration of our third question—which has a very important bearing on medico-legal cases and likewise on the diagnosis and treatment of myelitis arising from syphilitic disease. Mr. Erichsen says[1]: "It would appear that surgeons and writers on diseases of the nervous system have included four distinct pathological conditions under this one term, "Concussion of the Spine," viz.: 1. A jar or shake of the cord, disordering, to a greater or less degree, its functions without any lesion perceptible to the unaided eye. 2. Compression of the cord slowly produced by the extravasation of blood. 3. Compression of the cord by imflammatory exudations, serum, lymph, or pus within the spinal canal; and 4. Chronic alterations of the structure of the cord itself as the result of impairment of nutrition consequent on the occurrence of one or other of the preceding pathological states, but chiefly on the third."

We have already paid our respects in full to those subjects included under the headings 1 and 2; but we have yet to deal with those embraced under headings 3 and 4.

There exists no reason to doubt that inflammation, having its origin in the spinal cord or in its membranes, may be either acute or sub-acute, or that the former need be developed at an earlier day than the latter. The important question before us for our consideration, however, is, How soon do traumatic inflammations arise after the receipt of the traumatism? This question cannot be definitely answered—the answer must necessarily be a mere approximation. Nevertheless, I think that observation and experimentation fully justify the statement that traumatic inflammation commonly makes its appearance within four days after the receipt of the injury. In support of the above, I will here present a series of experiments which consisted in fracturing the right leg of twenty rabbits[2]: "This was done without producing a single compound fracture. The temperature details were as follows: Average temperature before the fracture 102·6; average temperature two hours afterwards 102·6; subsequent daily average temperature, first, 102·6; second, 102·6; third, 103·1; fourth, 103·1; sixth, 103; eighth, 103·1; tenth, 102·8; twelfth, 103; fifteenth, 102·8; seventeenth, 103·2; nineteenth, 103; twenty-second, 103."

In the case of the brain and spinal cord, when there is no open wound communication with these organs, the danger of inflammatory action is greatly diminished. Furthermore, the trivial character of lesions produced by concussion, and also the exceeding rarity of the traumatism—except when it is produced by lightning strokes, electric shocks or gun-shot wounds—all combine to impress me with grave doubts in regard to its being followed by inflammation. In fact, there is not sufficient proof to justify the conclusion that any case of traumatic myelitis, or meningo-myelitis, has ever had its origin from molecular disturbances or any pathological lesions which were invisible to the unaided eye, in an otherwise healthy spinal cord or its membranes.

Let us now briefly examine the history of concussion, in order that we may, if possible, discover how these troublesome errors were engrafted on the profession. The history of concussion dates from 1705, when M. Littre published his famous observations. A prisoner struck his bowed head against the wall of his cell and fell dead. The inspection of the head failed to reveal a contusion, tumor or wound in the scalp or a fracture of the skull. The cranium was opened when it was discovered that the brain did not nearly fill the interior of the skull, while the entire brain substance seemed harder to the touch —more compact than usual. This observation has been reported hundreds of times, and it was long claimed that it demonstrated the fact that a violent shaking of the substance of the brain was capable of producing death without any appreciable lesion. Permit me here to call attention to the fact that in the report before me there is no evidence to show that there was any post-mortem examination made of any portion of the body except the head. The autopsy of the head, viewed in the light of modern science, is entirely worthless; while the position in which the head was placed at the moment the injury was inflicted, suggests the possibility of a fracture or dislocation in some portion of the cervical region of the spine. It may be well to call attention to the fact that in this case, and all other cases of concussion reported prior to the middle of the present century, the microscope was not em-

[1] On Concussion of the Spine, p. 16. London, Longmans, Green & Co., 1882.

[2] Amputations and their Complications, p. 525. By B. A. Watson, M. D., Phila., P. Blakiston, Son. & Co., 1885.

ployed to aid in the discovery of the pathological lesions. Post-mortem examinations were very rarely made, even in cases of concussion of the brain, and consequently the case reported by M. Littre was accepted as a typical one. M. Littre, at the time he reported this case of so-called concussion of the brain, had become famous in the medical profession and, therefore, the following may be very properly applied to him: "Great errors seldom originate but with men of great minds."—Petrarch.

Mr. Erichsen in writing on concussion of the spine, in 1875, remarks:[1] "There is little opportunity, reason, or excuse for a post-mortem investigation of that structure, which is probably the one that is least frequently examined in the dead-house, viz., the spinal cord, as it is the one, the correct pathological investigation of which, is attended by more difficulties than that of any other organ of the body. So rare are post-mortem examinations of these cases, that no instance has occurred to me in hospital, or in private practice in which I could obtain one; and, with one exception, I can find no record in the transactions of societies or in the periodical literature of the day of any such instance. The only case, indeed, on record with which I am acquainted, in which a post-mortem examination has been made of the spinal cord of a person who had actually died from the remote effects of concussion of the spine from a railway collision, is one that was published in the 'Transactions of the Pathological Society,' by Dr. Lockhart Clark. He had been in a railway collision, and without any sign of external injury, fracture, dislocation wound, or bruise, began to manifest the usual nervous symptoms. He very gradually became partially paralyzed in the lower extremities, and died three years and a half after the accident." There is no reason to believe that this man died from even the remote effects of the traumatism. The history of this case entirely fails to connect the disease from which the patient died with the railway collision. Therefore it may be properly said of those who base an argument on this and all similar cases:

> "When people once are in the wrong,
> Each line they add is much too long;
> Who fastest walks, but walks astray
> Is only farthest from his way."
>
> —Prior.

A NEW OPERATION FOR HARELIP.

BY CHRISTIAN FENGER, M. D.,
CHICAGO.

In all forms of harelip we find not an excess, but rather a defect of labial tissue—mucous membrane, prolabium and skin. The two portions of the upper lip, when brought together, are too small to form a lip of normal shape; it would require the interposition of a triangular piece of lip with apex towards the nose and base toward the border of the lip to obtain at once a lip of normal shape. The tissue defect is greatest in the skin, less manifest in the mucous membrane and prolabium; still in the majority of cases of complete harelip, the defects in these tissues also may be considerable.

It would thus seem natural to select a method of operating by which no tissue should be lost. In all the older methods the so-called "freshening" of the surfaces to be united requires the removal of at least a part of the prolabium, in some more, in others less, at the best as in the method of Nelaton; for small harelip, a displacement downward, to form a projection which must either disappear by retraction and atrophy or be removed, if present in excess, by a secondary operation.

About five years ago I was led to consider this question in a case of double harelip with rather defective lateral portions, in which I operated after the old method, and suppuration with consequent non-union took place. At the next attempt at union, the increased defect of tissue made union still more difficult than at the first operation. I therefore concluded to operate in my next case without the removal of any tissue, so as to have, at least, not lost anything in this respect if suppuration and non-union should make one or more later operations necessary. When I commenced to operate in this way I found it necessary to apply a separate row of sutures to the prolabium before bringing the edges of the skin together, thus closing the wound toward the mouth, and I soon found this to be a protection against infection. I have since that time never had any reason to abandon this method for any of the older methods.

I. OPERATION FOR UNILATERAL HARELIP.

1. *Incision.*—The incision is made at the border of the skin and prolabium, four to six millimeters or two to three lines deep, care being taken to guard against opening through the mucous membrane into the mouth.

It is necessary to draw the lip down in order to procure sufficient tension for the knife to divide the tissues; this traction causes anæmia of the border of the lip, making the line between the white skin and red prolabium indistinct. It is necessary to be careful to have the incision precisely in this line, because a small margin of prolabial tissue left with skin will, as I have seen in one case, leave a red brim along the line of union, necessitating a secondary operation for cosmetic reasons.

The length of the incision downward and outward depends upon the shape of the two portions of the separated lip. It is unnecessary, at the beginning of the operation, to estimate the length correctly, as the incision can be prolonged later on after some of the sutures have been applied and tied, according to the requirements of the shape of the lip when united.

2. *Sutures of the Prolabium.*—Interrupted sutures of fine silk are applied or inserted from the mucous surface so as to place the knot of the suture in the mouth, the first suture close to the top of the triangle as shown. The ends of the sutures are left long and held together with an artery forcep which is left hanging down. The succeeding sutures are applied in a similar manner at a distance of from three to five millimeters from each other in a number corresponding to the extent of the line of prolabium to be united. These prolabial sutures should include the mucous membrane and sub-mucous tissue only, or as little tissue as will suffice to keep the prolabial edges together. There must be no tension whatever at the line of union; if tension exists from shortness of the labial flabs, it must be overcome by the tension sutures which will be described later.

When, apparently, a sufficient number of these sutures have been applied, they are tied from above downward, or from the nose to the prolabium, the upper or nasal suture first, the forceps being held up toward the forehead. The united line must be long enough to give sufficient length to the lip and permit the lowest point of union to be a little lower down (toward the lower lip) than the sides of the lip and the corners of the mouth. The wound to be united is now closed against the mouth—is made a subcutaneous wound.

3. *Sutures of the Skin.*—(1.) Tension Sutures. According to the size of the defect, one or two tension sutures become necessary. I have entirely discarded the figure-of-eight suture with hairlip pins and also the button and shot sutures, and always employ an interrupted suture, using silk a little heavier than that used for the coaptation sutures of the prolabium and skin. In ordinary cases of single harelip one tension suture is sufficient. This suture enters the skin at a distance of one-quarter to half an inch from the cutaneous margin of the wound and is passed deeply down into the tissue of the lip. Care is taken not to have it pass through to the mouth, but to have it take in about two-thirds of the tissue of the lip, as this tension suture should be placed at or near a point where the margins of the wound are the greatest distance from each other—that is, near to the prolabium of the undivided portion of the lip. The tension suture is left with long ends held by artery forceps, and should not be tied until all the cutaneous coaptation sutures have been inserted.

(2.) Coaptation Sutures: These sutures for which common silk twist (which may be bought in dry goods stores, and disinfected in the usual manner by boiling it from fifteen to thirty minutes in a five per cent. solution of carbolic acid) is used, are applied from above downward, or from the nasal angle of the wound to the prolabium, at a distance of three to five millimeters. Three to five sutures are usually required. The lowest suture is passed through the ununited borders of the prolabium.

The wound is now carefully cleansed by small aseptic sponges and is finally touched with a sponge wrung out from a two and a half per cent. carbolic acid or a 1 to 2,000 sublimate solution.

If any hæmorrhage is present, it is stopped by continuous pressure, with an aseptic sponge, for a few minutes; if the hæmorrhage is slight it will cease upon tying the sutures.

The closure of the sutures should begin with the tension suture, so as to prevent the coaptation sutures from tearing through, as they would be liable to do if tied before all tension was done away with.

If, in drawing the sutures together, it is found that the middle of the lip does not come down low enough, or that there is still an indentation in the prolabium at the line of incision, it is advisable to prolong the cutaneo-prolabial incision a little on one or both sides, as the shape of the lip may require, and then apply an additional cutaneous coaptation suture.

When the cutaneous sutures are tied, the united wound should present the appearance shown.

4. *Dressing of the Wound.*—After careful cleansing of the line of the wound with

saturated solution of boracic acid, a layer of finely powdered boracic acid is dusted on, and a cotton-collodion dressing applied. When I began to use this method, I plugged the nostril with borated cotton, but on account of its inconvenience to the patient, have now discontinued this practice. I do not use iodoform-cotton or iodoform-collodion dressing, for fear of iodoform poisoning; I prefer to have the nurse or mother dust finely powdered boracic acid into the nostril every three or four hours during the day.

A single or double strip of rubber adhesive plaster extending from ear to ear is applied over the collodion dressing in such a manner as to draw the two cheeks somewhat together, for the purpose of immobilizing the cheeks and lips when the child cries or nurses.

The dressing may be changed once a day, or every two or three days, if it remains dry. If, however, the dressing becomes soaked by nasal secretion, or milk when the child is nursed, it should be changed according to the necessity of the individual case.

5. *Removal of Sutures.*—The cutaneous coaptation sutures are removed after a week: the tension suture is allowed to remain two to four days longer, if it has not been loosened by pressure atrophy or pressure necrosis of its canal. After removal of the sutures, the borated cotton-collodion dressing and adhesive straps are re-applied to be continued until the suture canals have entirely healed, which takes place toward the end of the second or third week.

At the junction of the two lateral corners of the wound, there often remains after the suturing, a small quadrangular ununited space one to two millimeters in diameter where it may have been impossible to approximate the edges of the wound. A very fine suture may help to close this little defect. If, as is often the case, this little suture cuts through, the small defect heals by aseptic granulation, requiring only very little more time than the primary union of the remainder of the wound. It leaves at most a small cicatrix in the line of union at the border of the skin and prolabium and does not result in permanent disfigurement.

The prolabial sutures will sometimes cut through and peel off if the process of healing goes on undisturbed, or some of the sutures may remain and be removed after the end of the second or third week, at a time when union is strong enough to tolerate the manipulations necessary for their removal.

II. OPERATION FOR DOUBLE AND COMPLICATED HARELIP.

The operation for double and complicated harelip is performed on the same general principles, namely:

1. *Incision.*—The incision along the cutaneo-prolabial border should be of sufficient length to cover the space of defect. A second incision should be made along the cutaneo-prolabial border of the median peninsula of labial tissue below the nasal septum, if this peninsula is so situated as to be avilable for use in the information of the lip.

2. *Suture of the Prolabium.*—The prolabial sutures are applied as just described for the unilateral harelip, to be tied on the oral surface of the wound. The sutures should be first inserted on both sides of the nasal peninsula until this is wholly covered and until both lateral halves of the prolabium come together at the median point of its lower border. When this point is reached these two rows of sutures are tied.

The lateral prolabial borders are now united in the median line as low down or as far out as required to give to the lip the necessary length, as described in the operation for single harelip. These prolabial sutures are tied in the mouth usually without any tension, because the prolabium, when loosened from the skin and retroverted, furnishes a flap of sufficient size and elasticity to permit of ready approximation.

It is important, as before stated, that the linear incision should not penetrate into the mouth. When, as is often the case, the cleft extends through the nostril or nasal cavity, there is a lack of prolabium near to and in the nostril, and the prolabial sutures cannot be applied high up. It is usually possible by careful dissection and separation of the mucous membrane at the oral fornix of the lateral half of the upper lip, to displace the mucous membrane to some extent laterally, so that the uppermost suture may be applied reasonably high up toward the nostril.

When the prolabial sutures have been tied, the wound presents the appearance represented.

3. *Sutures of the Skin.*—Tension and coaptation sutures are now applied as follows:

(1.) Tension Sutures: For these sutures somewhat heavier silk should be employed. The upper suture should be inserted at the lower border of the nasal peninsula, the lower one near the lower border of the lip. They should be passed in and out at a dis-

tance of a quarter to half an inch of the border of the skin, and should include one-half, or a little more than one-half of the thickness of the lip. The ends should be held by artery forceps and should not be tied until all the skin sutures have been applied.

(2.) Coaptation Sutures: The coaptation sutures are now inserted from above downward. The first two or three sutures are inserted on both sides, between the lateral skin flap and the skin of the peninsula until this is united to the side flap throughout its entire circumference. The lateral flaps uniting in the median line just below the nasal peninsula, forms the upper portion of a Y-shaped line of union. Then the lower portion of the wound is united by two or three sutures, and a lower fourth suture is inserted through the two halves of the prolabium.

After thorough cleansing and disinfection of the wound, the sutures should be tied; first, the tension, and then the coaptation sutures.

4. *Dressing of the Wound.*—The wound should be dressed with borated cotton-collodion or in older patients, with iodoform-collodion. The nostrils, especially in older patients, should be loosely packed with borated or iodoform cotton. Over this, two straps of adhesive plaster should be applied. In older patients a strip of iodoform gauze should be laid in the mouth along the line of union of the prolabium. In new-born children the nostrils need not be packed with cotton and no iodoform gauze should be used: but these localities should be frequently dusted with finely powdered boracic acid. The dressing should be changed according to the amount of discharge, never more than once daily.

5. *Removal of Sutures.*—The coaptation sutures of the skin may be removed at the end of the first week; the tension sutures according to the amount of tension remaining, usually late in the second week; finally, what may remain of the prolabial sutures should be removed still later when the union is so solid that the upper lip is able to tolerate manipulation.

It is immaterial how narrow the new upper lip may appear to be immediately after the operation. Konig remarks (in speaking on plastic operations on the lips—keiloplastic operations following the extirpation of labial carcinomas) that the shape of the mouth, however deformed it may appear, on account of unequal size of the lower and upper lip in the first weeks after the operation, that in the course of some months the shape of the oral orifice and lips becomes more and more normal, surprisingly so when a sufficient time, from three to six months, has elapsed.

The all-important feature of the operation is to make the upper lip long enough in a sagittal direction, and to have exact union of the lower portion of the prolabium.

Apparatus to draw the cheeks together for the sake of immobilization or to diminish tension I have up to this time found superflous.

CONCLUSIONS.

The two main points in this harelip operation are the incision and the prolabial sutures.

1. The incision, a linear incision, is similar to that made in the operation for laceration of the perineum as proposed by Lawson Tait, and by him termed "flap-splitting." As stated above, this possesses the advantage of not sacrificing any tissue of the parts already more or less defective; on the other hand, repeated denudations made necessary by unsuccessful attempts at union would tend to make the lateral portions of the lip smaller and smaller. Furthermore, the linear incision, by loosening the everted prolabium (which is readily converted into mucous membrane by the simple change of position into the oral cavity) furnishes so much tissue for the posterior surface of the lip that union of the prolabial borders is easy, even before any tension sutures have been applied.

2. The prolabial sutures should be accurately applied. Fine curved needles should be used, the sutures made of fine silk. Interrupted sutures should be employed, in sufficient number and at sufficient intervals to furnish exact union. These sutures close the wound against the mouth and make the wound, so to speak, cutaneous instead of visceral, and thereby prevent infection from the ever-present multitude of microbes in the mouth. I believe that this suture will prove to be a potent factor in securing uniform results by preventing suppuration and non-union of the wound.

3. The cosmetic results have been all I could desire. If a slight indentation at the line of union of the prolabium has existed immediately after the operation, it has generally disappeared after a few months, provided the lip has been made long enough at the time of the operation.

4. I think that this method is applicable in all cases and should take the place of all the numerous older methods of operating.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

FORTY-SECOND ANNUAL MEETING, HELD IN WASHINGTON, D. C., ON TUESDAY, WEDNESDAY, THURSDAY AND FRIDAY, MAY 5, 6, 7 AND 8, 1891.

The Address of Welcome.—The proceedings of the general session were opened at Albaugh's Opera House, with an address of welcome to the members and delegates by the Hon. J. W. Ross, one of the Commissioners of the District of Columbia. He characterized the association as representing a constituency more numerous and powerful than any other on the face of the globe and one whose influence could not be over estimated. No similar organization ever occupied the vantage-ground held by the association for the discussion of topics calculated to enlarge its usefulness and power. One of the primary objects at which it was aiming was the promotion of such legislation as would tend to strengthen the profession in the performance of its duties. As a member of the bar he had often marveled at the fact that the common law, which respected the confidence that should exist between counsel and client, did not extend the same privilege and protection in the case of the physician and his patients. If any communication should be absolutely sacred and beyond the inquisition of the witness stand, it should be the statements made by an individual to his medical adviser. He thought that the time had come when any suitably expressed statements of the rights and requirements of the medical profession in this matter to the great body of lawmakers in Congress would be treated with the most profound respect.

The President's Address.—In the course of his address the President reminded his hearers that they were met solely for the promotion of science and for the good of the human race, to maintain the honor and dignity of the profession, and to hold aloft the flag of honorable medicine. They were there to lay their contributions, the results of study and observation, upon a common altar for the common good; to worship at the sacred shrine of medicine and to renew their fealty to the noble profession to which they had devoted their lives and linked their fortunes. As physicians they had an almost superhuman mission to fulfil. The chief object of their professional work was to preserve life and insure health. The goal of their ambition and desire was almost at the end of human capacity. It was their province as well as desire to know all the secrets of natural organization. They would have the formative crystal and the germinal spot made transparent. They would enter the microscopic world and witness the wonders therein revealed, and would, if possible, search into and unravel the very mysteries of the vital principle. To this perfect knowledge did they aspire. It was doubtful if man's intellect, great as it was, could ever compass all that he so earnestly desired; yet, by constant and faithful work, he might approach nearer and nearer to its consummation. In every part of the habitable world, blessed with the light of civilization, active, busy members of the profession, endowed with high culture and incited by the noblest resolves, were enthusiastically engaged in unraveling the mysteries of disease and seeking means and methods of treatment for the mitigation and relief of suffering and the prolongation of life. That the full benefit of the labors of American physicians might be attained and utilized, it was essential that the members of the profession, scattered over an area of country of almost inconceivable magnitude, should be brought into associated action and be organized into a body whose influence might be exerted over the length and breadth of the land, until a correct and noble sentiment was engendered in the mind of every member of the profession.

One of the great benefits conferred by the association was the establishment of an *esprit de corps* in the profession by the preparation and adoption of a code of ethics which comprised the great principles of truth, honor, and justice in regulating the relations of physicians to each other, to their patients, and to the public. This should be and was the written law, clearly defined, and of acknowledged force and effect, that prevailed from one end of the country to the other. It formed an impassable barrier between the sheep and the goats, the clean and the unclean, the physician and the charlatan. The strict observance of this code had done more than anything else to maintain harmony in the profession and to elevate it in the public estimation. It embodied the true spirit of the golden rule. Every one who entered the profession should be provided with a copy of the code, and should make it the guide of his medical life. It would serve as a talisman to the young physician, and would be the best safeguard against snares and pitfalls. It would seem that every honor-

able and high-minded member of the profession would be willing to indorse and be controlled by this code. It was to be regretted that there were some, who undoubtedly possessed a high order of talents and were justly distinguished, who had still an utter repugnance to the observance of certain parts of the code, and who held themselves aloof from the association in consequence. These gentlemen were probably as proud of the noble profession to which they belonged as any others were, and were equally anxious for the advancement of its interests, but could they censcientiously affirm that the motives by which they were influenced were pure and unselfish? Should these members put their opinion against the unbiased and unselfish judgment of the wisest and most experienced in the profession, nine-tenths of whom were guided in their actions by the spirit and letter of the code?

The fundamental and chief object of those who had originated the association was the improvement of the American system of medical education, and the elevation of the standard of requirements for the professional degree. Never had there been a greater expenditure of effort illumined with genius and learning to accomplish these two great objects, and, though many of the ideas were, in a country so diversified in character and extent, probably somewhat Utopian, there had been a gradual elevation of the standard of education fully equal to the progress of the country in every other department of human learning. The speaker was ready to maintain that the advantages and facilities for medical instruction in this country, even at the present time, were quite equal to those of any other, and that the medical colleges had produced as able, learned, and successful practitioners as had ever been graduated from other institutions. While he was willing to admit that our trans-atlantic brethren had excelled in experimental work, this country had taken the lead in all the practical departments of medical science.

Now that the Medical College Association had adopted all the requirements for improved medical education which this association had been so long urging, and for which in fact it was established, it was eminently proper and important to pass a resolution that after the changes contempleted had gone into effect no medical man who had received a degree from a college that had not adopted the improved method of teaching, and no professor or *attaché* of such college, should be eligible as a delegate or member of the association. This great moral support was due to those colleges which had so heartily taken up the burden that the association had for nearly half a century carried on its own shoulders.

It might be well to call attention to the fact that original research and experimental investigation had not received the attention from American physicians which their importance demanded. The government, while the most liberal and best in the world, had never seemed to comprehend that the cause of science would be greatly advanced and its own honor increased by the establishment of schools for original investigation and experimental research. It had not kept pace with other enlightened governments in scientific enterprises. Such work must in the very nature of things be left, for the present at least, to the progressive spirit that animated the universities and to private laboratories which were being established in different sections of the country. It would probably be advisable to establish a Section in Experimental Research, which would tend to advance science and be greatly to the interest of the work of the association.

It had been a happy conception of one of their most distinguished presidents to make the establishment of an association *Journal* the burden of his inaugural address, and so powerfully had he impressed the minds of the members that a journal had sprung into existence which had in a short time given evidence of its power in the advancement of its purposes. It might require years to bring it to the desired standard. To effect so desirable an object it was necessary to make provision for an ample annual income. Nothing less than from seventy-five to a hundred thousand dollars should be considered ample. Next in importance to its financial needs was the selection of an editor, able, learned, and highly endowed with editorial tact and business qualifications, who would devote all his time and talent to his editorial duties. He should be empowered to spend money liberally in obtaining scientific material, original communications, translations, and reviews from every part of the world. He should have absolute control in the selection of matter for the journal. To such an editor a salary should be given that would render him independent. The sum should be not less than ten or fifteen thousand dollars a year. The necessary funds could, by proper exertion, be easily raised, and would

not only sustain the journal in the best style, but afford a sum in addition which could be used in many ways to the advantage of the association. The future location of the journal was a matter of such importance as to require careful consideration. Its weal or woe might depend upon the action taken at the present meeting. It had been suggested that the *Journal of the American Medical Association* should be moved to Washington, and it had been determined to submit the question to the members and delegates present at this session. He would beg the delegates and members of the association to consider well every side of this question before committing themselves to a vote. The *Journal* had now its home in Chicago, and had been there for eight years. It had already become the peer of many of the great weeklies of the country, and, if properly sustained by the profession and wisely and energetically conducted by its managers, it would become the recipient of the best thoughts of this country and the worthy exponent of the American profession. It had been proved that it could be more economically published in Chicago than in Washington, which latter city was by no means an important scientific or professional center. But it was the great center of American politics, to which everything was made subordinate, and it would be impossible, if the *Journal* was published in that city, to prevent its becoming contaminated by the political air.

The Relations of Contract Surgeons to the General Profession.—A special committee, appointed last year by the Medical Society of West Virginia to consider this subject, memorialized the association and appealed for its active co-operation to effect the redress of alleged abuses. The memorialists asked consideration of the question as to how far the rules adopted by railroad corporations for the government of the surgeons in their service infringed upon the rights of the profession at large as set forth in the code of ethics of the American Medical Association. It was well known that large bodies of men were in the employ of these corporations, and that these men lived in widely-scattered communities. The corporations had established systems of employing contract surgeons to attend to employees and passengers injured by accidents. It was also well known that these corporations had adopted rules for the government of the surgeons and of those injured which demanded that these surgeons should assume entire charge of such employees or passengers when injured, regardless of the rights of any outside medical men who might have been summoned and be in attendance upon the injured prior to the arrival of the company's surgeon, even though the physician first in attendance might be the family physician of the injured person. Notice had been given in most cases by the railroad companies waiving all responsibility in respect of injuries treated by non-contract men. It was assumed by the memorialists that this condition of affairs placed the contracting surgeons in direct conflict with the spirit of the code of ethics, and was an infringement upon the rights of the physician first called. The practice of accepting passes as compensation or in lieu of the regular fees was detrimental to the profession's interests by lowering the standard of surgical services, and was further demoralizing. It gave to these wealthy corporations services at far lower rates than the profession charged to individuals. It seemed that if members of the profession were at liberty to make contracts to furnish an unlimited service of the kind referred to for passes, and in some cases for small fixed money payments, without affecting their ethical standing, all stigma of unethical or unprofessional conduct should be removed from those of the profession who contracted with private individuals to furnish medical or surgical services, including medicines, by the month or year for fixed sums. A special committee was voted to sift the facts in respect to the points alleged in the memorial.

The Rush Monument Fund.—This subject was again brought before the association by Dr. A. L. Gihon, who for the seventh time reported slow progress toward the accumulation of the required fund. He made an earnest appeal for more enthusiasm in the matter, and propounded certain schemes that might be adopted for the purpose of raising the necessary money, which were approved.

The Address in General Medicine.—Dr. E. L. Shurly, of Detroit, delivered this address. He said he should present for consideration some points bearing on the relation of micro-organisms and toxines to the so-called zymotic or infectious diseases. Though laboratory work had done more than any other branch of science toward clearing up many vexed questions about physiological and pathological activities, yet, to be of lasting value and guidance, it must agree with general and clinical obser-

vation, and there were instances where laboratory and clinical observations had crossed swords. He was aware that it was generally accepted that bacteria or their spores were the essential cause of most, if not all, of the infective diseases, and the results of bacteriological investigation during the last few years would seem to support such a doctrine for the following reasons: 1. They could be isolated by color reactions and thus directly connected with the diseased body when found. 2. They required a certain time for development, corresponding to the period of incubation of such diseases, many of them being ectogenic and saprogenic, anaerobic or aerobic. They could thus live until the opportunity for invasion offered. Being endowed with life and multiplying enormously, they could resist destruction, Being protoplasmic and microscopic, they could more readily affiliate with animal fluids, cells, and tissues existing in a passive or quiescent state as well as in an active one. They could behave like vegetable seeds or spores, and preserve a long period of latency. For these and other reasons that might be adduced, we were led to believe that bacteria must be the cause in some way or other of the zymotio infectious diseases. But the question arose, How did they effect this result? Was it by mere local growth as parasites, or by the secretion of a material from themselves? In other words, were they secreting cells or did they induce at once chemical changes or fermentation of a destructive character with the formation of poisonous substances? It would be seen that many observers who were strong in their faith in the microbic origin of disease had not in every instance looked fairly at the question. The statement that no case of genuine cholera had as yet been reported in which the comma bacillus was absent had been disproved. In what bacteriological life were exemplified certain effects that had been observed connected with development? The career of bacteria *ad interim*, from one animal to another, was not well known. In the case of many of them, spores had never been demonstrated or their behavior formulated. Most of the species were destroyed by the healthy fluids or tissues, and hence their destiny depended upon a favorable nidus or pabulum, which meant disease. It was obvious that artificial culture in media outside the body or in the lower animals could only approximately reflect their real natural growth and development, for in no instance was it possible to transfer the artificially cultivated micro-organisms to an animal with the absolute certainty that nothing else accompanied the bacteria. The certain species only appeared to be pathogenic implied a state of specialization analogous to that of living nucleated cells. That their action was local primarily in all cases might be assumed, because their behavior in no way showed that they themselves invaded or maintained their existence in the blood or lymph. Therefore it was possible that pathogenic bacteria developed only where previous disease or an abnormal state of the body suitable to them existed; that, having found such, they took root, as it were, and by their catalytic action primarily, and secondarily by giving rise to a particular toxine, which in turn acted selectively as a tissue poison. If the bacilli of tuberculosis immediately produced the several diseases known as tubercular, why should any previously prepared nidus be necessary? If they or their still undemonstrated spores were constantly invading us, which was undoubtedly true, they must at once be destroyed, or, by gaining access to the fluids of the body, must set up, mechanically or otherwise, inflammation and their peculiar effects as any other foreign body would. But, as such micro-organisms must find just the proper conditions for development or not develop, we might assume that such a result implied previous disease, such as caseation, whether tuberculous or not. Complex and delicate processes attended the changes of proteids, and by radical or atomic substitution one might be changed readily into the other. We could see how probable it was that these micro-organisms might operate by a peculiar property which enabled them to decompose or exercise a catalytic action on certain states and kinds of proteids. It was manifest that diseases arising from the presence or entrance of micro-organisms must be therapeutically treated by attacking the cause or neutralizing its operation. The bacteria produced for themselves, or from the organic substances which they attacked, a poison which could be cultivated outside the body in some instances. Pathological chemistry had not demonstrated with exactness the nature of all these poisons, or classfied them, but it was fair to believe that this would be done in the near future. Although it was generally supposed that inorganic chemicals were not tissue poisons, but acted only upon the functions through the nervous system, still this view did not obtain when we observed the changes produced by iodine, bromine,

phosphorus, arsenic, and the silver, gold, platinum, and cupric salts, besides some of the vegetable alkaloids. In consideration of the changes that many of the remedies underwent in the stomach and intestines by oxidation or other processes before their absorption, it seemed to the speaker that the rational mode for the administration of drugs was to give them hypodermically, and in this way it was possible to command effects which could not otherwise be attained. Dr. Lauderer had obtained beneficial effects in phthisis from hypodermic injections of balsam of Peru. Behring had recently found that a number of chemical substances used hypodermically—such as aurochloride of sodium, naphthaline, and trichloride of iodine—were capable of neutralizing the poision of diphtheria in guinea-pigs, the latter substance being the most active of all. The same observer had also practiced in diphtheria, and with good effect, the inoculation of animals with bacillus cultures. Better effects had been obtained from the administration of bromide of gold by injection than from the bromide given in the ordinary way. The prompt results in the treatment of erysipelas with carbolic-acid injections were well known. The superior effects of the treatment of syphilis by the hypodermic injection of cyanide and bichloride of mercury and chloride of gold and sodium were striking. The hypodermic injection of chlorodyne in profuse diarrhœa was superior to its administration by the mouth. Ergot administered, even in considerable quantities, by the mouth would often fail, whereas one, or at most two, hypodermic injections of one-tenth or one-fifth of a grain of ergotin would generally stop a severe attack. Digitalis also acted upon the cells and vascular system more certainly when so administered. He might also mention the beneficial effects of strychnine used in the same manner in typhoid conditions. That animal poisons could be neutralized in the body he believed would soon be generally demonstrated. The recent experiments of Tyndale, of New York, for the cure of tuberculosis by vaccination promised well. Hemmeter had stopped the diphtheritic process by the inoculation of the patient with an erysipelas toxine, and it was stated that persons suffering from tinea tonsurans were proof against diphtheria. This would seem to show that there must be a sort of antagonism between animal and chemical poisons. Why could not more universal application be made of this principle with a view to obtaining more specific therapeutic agents? His object in choosing this subject had been to awaken a more general interest in physiological and pathological chemistry, and thus hasten the period of release from empiricism.

The Address in Surgery was on Stricture of the Rectum; its Ætiology, Pathology, Symptomatology, Diagnosis, and Treatment, by Dr. J. H. Matthews, of Louisville. He said he realized that in discussing this subject he should take positions contrary to the accepted teachings of the day, but assumed that the one great object of the meetings of this association was to elucidate and discuss subjects that were in doubt, those that were mooted. In considering the classification of the varieties of stricture of the rectum as given by Dr. Kelsey, he said that the idea intended to be conveyed by the term was that of a pathological change in the tissues, a deviation from the natural state brought about by disease; hence he objected to the consideration of congenital malformations of the rectum, or to defining them under the head of strictures of the same, for the reason that it was misleading to do so. It would be more to the point to call them atresias of the gut. Exception could also be made to the term acquired, stricture, and it was very easy to understand how one could acquire a stricture as the result of venery, but difficult to understand how one could acquire a spasmodic or cancerous stricture. He would adopt, for the sake of discussion, the classification into—

1. *Spasmodic.*—To this form of stricture he should prefer two objections. First, if it was true that such a condition ever existed, which he doubted, then it should not be classed as stricture at all, for the reason that no pathological change was manifest such as was necessary to constitute a stricture, and no treatment could be given in *per se*. In other words, it would be a symptom of some lesion or trouble outside the one called stricture. Secondly, he believed that, from the anatomical construction of the rectum, it would be utterly impossible for its lumen to be so constricted by spasmodic contraction of its muscular fibers as to be perceptible as an obstruction. In all his examinations of this part of the gut he had never seen a spasmodic contraction that could be called a stricture.

2. *Dysenteric.*—Although it was frequently stated that dysentery was a common cause of stricture of the rectum, he had never seen a case that convinced him of the truth of the statement or that it was a cause at all. He had many times seen patients

who gave him a history of having had dysentery; and who were treated for a long time for the affection; but close scrutiny of the case had revealed the fact that the so-called dysentery was caused by an already existing stricture and ulceration. Dysentery was the result, not the cause, of stricture. If a long-continued irritation was kept up in the rectum from any cause, the result would be, of course, an inflammatory exudate, resulting, perhaps, in ulceration and stricture; but, in searching for this as a cause, the road to a conclusion had not been plain enough for him to put dysentery in the list as a cause at all for stricture of the rectum.

3. *Tubercular.*—Since the discovery of the tubercle bacillus it was self-evident that tuberculosis was often met with in the mucous membrane and other structures of the rectum. If stricture and ulceration was the term used, he could make no objection to the classification of tuberculosis as a cause of ulceration. That ulceration frequently resulted from this diathesis or dyscrasia no one could doubt, or that the coincident stricture followed as from other well-known causes—notably syphilis—he could not agree. The disposition of tuberculous tissue everywhere was to break down. Before the capacious rectum was filled with tubercular deposit sufficient to stricture it, it would have broken down from ulceration, and so on; and it must be by deposition only that we could conceive of stricture from this cause, because cicatrization was so rare and so feeble in these parts that it would be the rarest accident to find it. In no instance had he ever seen a stricture of the bronchial tubes the result of tuberculosis. There would be just as much reason to expect it here as in the rectum; indeed, more.

4. *Inflammation.*—This term was so broad and comprehensive that we must admit inflammation as a cause of stricture of the gut—indeed, as the one grand and common cause. In no other way could a stricture be formed. It might be argued that a lesion or wound existing in the bowel, by the reparative process healed and left cicatricial tissue, and that the stricture was the result of the cicatrix, and not of plastic infiltration of the tissue. But there could have been no cicatrization if there had been no inflammatory process. If he were asked what was the prime cause of stricture of the rectum, he would answer, Inflammation. What caused the inflammation in many cases he did not know, but, ordinarily, it was syphilis, cancer, or trauma—if by trauma was meant a wound or lesion from any or many causes. Outside of the two first named, cancer and syphilis, he was satisfied that no one could tell the cause that originated the stricture. He wished to reiterate that, outside of these two well-recognized causes for stricture of the rectum, he was not prepared to admit any other as a well-known, recognized, indisputable cause.

After elaborating the points in the diagnosis and pathology of stricture, the speaker went on to deal with the question of treatment, premising that he should adhere in the strictest sense to the pathological condition—namely, a stricture. This entirely ruled out the treatment of proctitis or the subsequent ulceration, which was one cause of stricture, and brought him directly to the means of treating that which was the result of said causes. It must be granted that many times ulcerations which would otherwise end in stricture were cured before that condition resulted. This could not hold in cancer, and possibly not in syphilis. The methods practiced to-day for treating stricture of the rectum were: first, dilatation; second, incision; third, electrolysis and raclage; fourth, excision; fifth, colotomy. Of course, under the division he had made, general treatment was ruled out, and the gradual dilatation of the stricture was objectionable for the reason that by this form of repeated irritation, more plasma was thrown out and the stricture surface increased. It might be true that some temporary relief was afforded, but upon the contraction of the tissue more was lost than had been gained. He did not hold the view that by the passing of bougies through the strictured surface absorption of the tissue was caused, but believed that the converse was true. Why forcible divulsion was seldom applicable in these cases he could not understand. If a fibrous stricture existed, forcible divulsion was the best method. To-day we did not fear hæmorrhage, because we understood how to control it. He was very positive, then, in saying that, if dilatation of a stricture of the rectum was decided upon, it should be a forcible and a radical one. He was very partial to incision or incisions for the relief of stricture of the rectum. Of the two operations recommended, internal and external posterior linear proctotomy, he preferred the internal. It was urged for the external, which consisted in not only cutting through the strictured surface but also in dividing the sphincter muscle, that it was all-important to get the necessary drainage. He did not think so—and if he did, he be-

lieved the ill effects of dividing the sphincters outweighed the matter of drainage. His plan was to introduce a three- or four-valve speculum and, after dilating sufficiently for the purpose, a long, sharp knife was used to divide the constrictions of fibrous tissue down to a healthy base—not only in the median line, but in several places around the circumference of the gut. He then placed a tampon, through which was inserted a metallic tube for drainage and the escape of gases. This tampon was aseptic and usually dusted with powdered persulphate of iron. On the fourth day it was removed and the rectum was irrigated with the mercuric solution. If the operation was done effectually, he had never seen the necessity of employing the bougies afterward for the purpose of dilatation.

Excision.—He thought a better term to employ here would be extirpation. Excision of a stricture of the rectum conveyed but little idea of the operation. He could not appreciate the idea of excising a benign stricture. Extirpation of the rectum for malignant disease was an ideal operation. It was an axiom in surgery that in operating for cancer the whole growth must be removed, together with the glands that were involved. If the growth extended beyond the point where it was prudent to operate, it was best not to attempt its removal, except, perhaps, for total obstruction, not with any idea of cure. Kraske's operation was admirably suited to cancerous stricture. It consisted in resecting the diseased part through an opening made at the left side of the sacrum. This operation was only applicable in a certain class of cases. If the sigmoid flexure was involved, it would be of no use. According to this method, the soft parts were divided in the median line from the second sacral vertebra to the anus. The muscular attachments to the sacrum were divided as far as the edge of the opening on the left side. The coccyx was removed, the attachments of the two sacro-sciatic ligaments to the sacrum were cut, and the soft parts were drawn to the left side. If still more room was necessary, it might be gained by removing a part of the lower left side of the sacrum. If the bone was divided on a line beginning on the left edge, at the level of the three posterior sacral foramina, and running in a curve with the concavity to the left through the lower border of the three posterior sacral foramina, and through the fourth to the left lower border of the sacrum, the more important nerves were not injured and the sacral canal was not opened. In this way the lower part of the rectum as far as the sigmoid flexure might be resected. It would be found in this operation that the dissection was a very difficult one.

As to colotomy, he was forced to conclude that none of the arguments in its favor, instead of other methods for cancerous stricture, could be substantiated in fact. If he were asked when colotomy was justified in cancer of the rectum, he would answer, Not at all. But if there was a total obstruction of the sigmoid flexure from a cancerous mass, colotomy would be justifiable. Whenever a stricture other than malignant, especially when caused by syphilis, was located in the movable part of the gut or in the sigmoid flexure, either causing total obstruction or about to cause it, colotomy should be done. By this we prolonged life indefinitely. If, then, it was decided to do colotomy, which of the two operations was preferable—the lumbar or extra-peritoneal, or the iliac or intra-peritoneal? He thought the anatomical phrase used in designating the two should decide it.

The Association's Journal.—The vexed question as to whether the publication of the *Journal* of the association should continue in Chicago or be removed to Washington, which it was supposed would form the subject of warm debate, was settled by an overwhelming vote to maintain the present arrangements.

Recommendations for change in the editorial and business management of the *Journal* were rife.—*N. Y. Med. Jour.*

Selected Formulæ.

TREATMENT OF ACUTE CORYZA.

According to Dr. Tissié, in the *Revue de Laryng., d'Otolog. et de Rhinolog.*, May 1, 1891, acute coryza may be dependent upon certain difficulties of the general nutrition. In such cases, to effect a cure, these symptoms as well as the local manifestations should receive the physician's attention.

Locally, Dr. Tissié claims efficacy for inhalations of a few drops of the following mixture, poured upon absorbent paper:

℞

Carbolic acid	5 grammes.
Water of ammonia	5 "
Water	15 "
Alcohol	10 "

M. et Sig. For inhalation.

Antipyrine will be found valuable in relieving the headache accompanying acute coryza. Finally, the author advocates the

use of the following snuff, five or six times a day:

℞

Sub-nitrate of bismuth	6.00	grammes.
Powdered benzoin	6.00	"
Carbolic acid	4.00	"
Menthol	0.20	"
Morphine	0.03	" M.

Donna, in the *Province Médicale*, speaks highly of the value of ichthyol similarly used.

METRORRHAGIA.

℞

Ergotini	10.00	grammes.
Aq. dest.	70.00	"
Glycerini	20,00	"
Acid salicylici	0.20	"

M. et Sig. One teaspoonful in three teaspoonfuls of water for rectal injection.

—Reinstadier, in the *Raccoglitore Medico*, April 30, 1891.

ARISTOL IN GYNÆCOLOGY.

Swieciki, in the *Raccoglitore Medico*, April 30, 1891, gives the following formulæ for aristol, which he claims to have found most efficacious in twenty cases of metritis, hyperplasia of the cervix, parametritis and eczema of the vulva.

I.

Aristol	5	grammes.
Powdered gum arabic	9.5	"

To make 5 pencils about 5 centimetres long.

II.

Aristol	0,50–1,00	grammes.
Cocoa butter	9.5	"

To make 10 vaginal suppositories.

III.

Aristol	5.00	grammes.
Sugna	5,00	"
Lanolin	1.80	"

M. et fiat unguentum.

SALICYLATE OF MERCURY.

For hypodermic injections Vacher uses the following solution:

℞

Hydrarg. chloridi corrosiv	1 part.
Sodii salicylici	2 parts.
Aquæ destil	100 parts. M.

In this solution each cubic centimeter contains one centigram of salicylate of mercury. For use by the mouth a 1–1000 to 1–5000 solution should be used.—*Deutsche Medicin. Wochenschrift.*

CHRYSAROBIN FOR HÆMORRHOIDS.

Kossubudski (*Bul. Gén. Ther.*) has used with success this remedy proposed by Unna. For external hæmorrhoids this ointment is used:

℞

Chrysarobin	gr. viij.
Iodoform	gr. iij.
Ext. belladonnæ	gr. vj.
Petrolati	ʒ iv.

Ft. ung.

For internal use, a suppository:

℞

Chrysarobin	gr. j.
Iodoform	gr. ½.
Ext. belladonnæ	gr. ⅙.
Olei theobromæ	gr. xxx. M.

For one suppository.

DYSMENORRHŒA.

Monin (*L'Union Medicale*) recommends the following for dysmenorrhœa of chlorosis:

℞

Alcohol of melissa, Tincture of saffron, Tincture of iodine	aa 1½ ounces.

M. Twelve drops daily, before each of the two principal meals, for two months.

Every eight days, a warm bath, containing three and one-half ounces of chlorate of ammonia.—*Univ. Med. Mag.*

PRURITUS.

The following are given by *La Semaine Méd.* for pruritus:

℞

Pure resorcin	ʒ j.
Glycerin	ʒ ij.
Water	ʒ iv. M.

Sig.—For external use.

℞

Menthol	ʒ iij.
Glycerin	ʒ ij.
Water	ʒ iv. M.

Sig.—For external use.

APPLICATION OF ICHTHYOL

According to the *Revue Générale de Clinique et de Thérapeutique*, Unna employs the following preparation of ichthyol in the treatment of diseases of the skin:

℞

Ichthyol	25 parts.
Starch	50 "
Carbolic acid	2½ "
Water	22 "

The ichthyol and carbolic acid are dissolved in the water while hot, and the starch added.

CHRONIC BRONCHITIS.

L'Union Médicale recommends the following pill for chronic catarrhal bronchitis:

℞

Turpentine, Tar	aa ʒss.
Balsam of Peru	ʒjss.

Benzoate of sodium, a sufficient quantity to make 80 pills.

Two of these pills may be given three times a day, in cases in which there is a marked catarrhal exudation into the bronchial tubes.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few para graphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

CURRETTING OF THE UTERUS IN PUERPERAL FEVER.

It is a surprising fact that while the microbic origin of puerperal fever has been recognized for some time, the use of the curette in these cases has only recently received any extensive consideration. If simple cleansing or irrigation of the parts proves insufficient to remove the cause of infection, one would surmise that the surgeon, at least, would at once attempt bolder and more efficacious means.

Fortunately, asepsis in child-birth has almost entirely done away with the possibility of puerperal infection, and this bugbear of obstetricians of a few years ago, has almost sunk out of existence. Yet, from varied causes, including carelessness from either physician or nurse, or pre-existing suppurative process, child-bed fever still manifests itself occasionally both in Hospital and private practice, and its prompt treatment is a serious question.

The rapidity with which death frequently follows the first symptoms of puerperal infection is remarkable, and brooks of no delay in treatment. Hecker reported a case, not long ago, wherein death occurred so quickly that a diagnosis of apoplexy seemed justifiable. The number of deaths from puerperal infection reported as occurring within the first twenty-four or forty-eight hours after the appearance of untoward symptoms, is startlingly large.

Could the physician know of the moment when infection has taken place, prompt removal of the infectious matter, by irrigations and douches, would surely prevent general infection. But this, unfortunately, is impossible.

In laparotomies, a prognosis may be advanced very early, for, if infected, the patient will usually show, within a few hours after the completion of the operation, signs of fear, restlessness, weakness and depression, before any objective symptoms have manifested themselves. It is not to be wondered at, therefore, that within a comparatively short time an incurable puerperal infection may be developed. Even in Hospitals, where the patient's temperature is taken three times a day, the attending physician is often forced to confess that he has come too late to render any help, or to stay the infectious process.

The question naturally arises as to whether —even although we have come apparently "too late,"—there is not some more energetic means than mere washing out of the womb, at our command, and can we not, by means of these more heroic measures gain what we have lost in time?

If, in general surgery, the operator arrives too late to effect primary healing or to perform a primary operation, cannot a more extensive operation be equally successful? The surgeon cuts, scrapes and cauterizes

until all dangerous substances are removed from the wound. Logically speaking, a similar therapeusis is surely applicable in puerperal infections. If irrigation and douching have failed, it is because by these means a removal of the infectious matter has not been effected. There may be two reasons for this. Either the patient has already become septic, and is, perhaps, lost; or, within the womb, there is still a colony of microbes, or in other words, a culture of streptococci. Should the former be the case—as subsequent symptoms in spite of all our efforts will show—the patient's fate is sealed, and it would only be cruelty to subject her to further operative interference. If general sepsis has not yet supervened, a thorough scraping out, or curretting of the womb, will frequently stop the infectious process.

It was in the above lines that Dr. E. V. Braun argued the feasability of the method advocated. The justification of the procedure will be better understood if puerperal fever is divided into three classes, viz., Pyæmic, Septicæmic and Sapræmic. In the last two classes, we are dealing with a process of decomposition in the womb; we find that saprophytes, and their ptomaines absorbed into the circulation have given rise to fever. There is no doubt but that a complete removal of this decomposing mass will effect a complete cure. As these sapræmic cases are usually light, and their prognosis good, there need be no question as to the justifiability of curretting.

So much for theory. Let us now review the practical value of the method, summed up from the experiences of operators both here and abroad.

Dr. Braun, in the *Arch. für Gynäkologie*, stated that this practice was adopted by him, especially in cases of sapræmic endometritis in child-bed. He used the method in 101 cases with the following results: Ninety-six of the cases were cured, and five died, but three out of these had already symptoms of general infection, a fourth died of purulent peritonitis attributed to escape of pus out of ostia of the tubes, and the fifth sank from hæmorrhage with septic symptoms ten days after the scraping. In over two-thirds of the 101 cases; the labor had proceeded normally, and there had been no visible evidence of any damage to the placenta, yet the curette never failed to bring away necrosed and putrid tissues, which, on microscopic examination, proved to be fragments of placenta or decidua. The procedure, according to Braun, is only to be undertaken in cases of rise of temperature in child-bed, due to endometritis. This complication can be recognized by the distinct arrest of involution of the uterus, fœtor of the lochia, and fever coming on early in child-bed without signs of pelvic inflammation outside the uterus. When signs of an extension of the inflammatory process are present, and, above all, where general infection is evident, scraping is contra-indicated. A rise of temperature sometimes occurs during the first week after the use of the curette, but Braun has never seen any parametritic exudation in his cases.

Both Braun and Dr. Heinrich Fritsch—who has of late given the subject careful attention, and contributed an interesting article in the *Deutsche Med. Wochenschrift*, April 16, 1891—agree that the operation is one comparatively free from danger. Hæmorrhages are seldom observed, neither is the procedure very painful. The uterus is washed out with a 1 in 1,000 solution of thymol before and after the scraping. The patient should be placed in the lateral position, the anterior portion of the os hooked carefully forward, and the vagina and perineum protected with a Sims speculum. In this way the womb may be scraped out without much inconvenience to the patient. That the womb may thus be thoroughly curretted has been shown by autopsies, and it is only in the folds of the cervix that the operation is not thorough. Braun, therefore, advocates a cauterization of this part. After the scraping and subsequent washing of the womb, an iodoform point is passed into the uterine cavity. Any abrasions of the vaginal mucous membrane are painted with pure tincture of iodine. The cervix and vagina are plugged for twenty-four hours, with iodoform gauze.

The danger of perforating the womb is but slight, especially if a broad, dull curette is used, and during the first days the womb is hard and firm. Here, however, we have varying opinions. Löhlein, at a *post-mortem* examination of a woman nine days after parturition, found the uterus soft and doughy. Liebman, of Triest, has also shown that in consumptives, and patients greatly run down, the uterus is easily perforated. Generally, however, in skilled hands, the operation may be safely performed, the uterus remaining firm until the fourth week.

Fritsch, while admitting with Braun the theoretic value of curretting for the removal of puerperal infection, nevertheless strongly condemns the general adoption of the methods, for the following reasons: first, because the differential diagnosis between sapræmic and streptococcic infection is most difficult at the outset; second, Fritsch asserts that the seat of the infection is neither in the decidua, nor in the contents of the womb; neither can we look upon the case in the light of a septic wound. The disease has a deeper seat, usually in the parametrium. Fritsch believes that the infection starts from the cervix, because this part suffers most severely in parturition, and as microbes may easily be deposited here, where lacerations are so frequent. The parametritis at the base of the broad ligament, is in the immediate vicinity, indeed, is almost a continuation of the wounded cervix. If the infectious matter is deposited on the surface of the dilated cervix, and this part is subsequently drawn together, the infection is thus mechanically carried to the deeper tissues, and is, therefore, undisturbed by irrigation. This infection is rapidly carried further in the loose tissue of the parametrium, and suppuration ensues. If the surgeon wishes to remove the seat of infection, large cuts should be made in the parametrium to facilitate the discharge of pus, or else the entire septic uterus should be removed. This, says Fritsch, would be rational. A partial removal of the decidua will certainly not accomplish the desired end.

If Fritsch, and others who argue similarly, are right, how do we account for the evidences of Braun's statistics which show a fall of temperature after curretting in 100 cases of puerperal infection? Perhaps, because all these cases were light, or it may be even that the subsequent irrigations and cauterization were productive of the good results and not the curretting.

Finally, it may be asked whether the method is ever positively indicated in these cases. To which it can only be answered that if the contents of the womb can be safely diagnosed as the cause of the trouble, it should be removed, and the procedure is as justifiable as the removal of a retained shred of the placenta. Further than this we cannot now go. The question is one, however, which critic and anti-critic will in time settle, and in the meanwhile these discussions and experiments may be watched with great interest.

CORRESPONDENCE.

COCAINE POISONING.

To the Editor M. and S. Reporter.—

Your editorial to-day raises anew the warning note touching cocaine and its dangers—one which the writer has sounded again and again, with a clinical support detailing nearly 300 cases, including 13 deaths.

In 1886, Dr. Wm. A. Hammond said, "he did not believe any dose of cocaine that could be taken was dangerous." That statement—mistaken and misleading—was promptly challenged by the writer, and that challenge so sustained by clinical facts in a paper: "Cocaine Dosage and Cocaine Addiction," read before the Med. Soc. of the Co. of Kings, Feb. 13, 1887; and another: "Cocaine Toxæmia," read before the Amer. Assoc. for the cure of inebriety, Nov. 8, 1887, that the British Med. Journal was impelled to say, editorially, "If it were needful to produce more proof of the unsoundness of Dr. Hammond's statement, Dr. Mattison has effectually done this."

In discussing my paper on "Cocainism," read before the D. C. Med. Soc., Washington, Dec. 24, 1890, Dr. Hammond confessed that he was wrong, and that nearly fatal results from cocaine had been noted under his own care.

In a fourth paper, "Cocaine Poisoning," by myself, read before the N. Y. Med. Legal Soc., March 9, 1891—to appear in THE REPORTER—the toxic record of cocaine was continued, making the most extensive resume of the subject ever presented.

Four words tell the story, COCAINE IS A POISON. Verbum Sap.

THERAPEUTICS.

HUMAN LYMPH IN THERAPEUTICS.

E. Magnat (*Le Bull. Médicale,* April 8, 1891) read a note to the Académie de Médecine on the employment of human lymph in the treatment of disease. The serous exhudation of blisters, which the author has designated as human lymph, was injected in cases laboring under a variety of diseases, such as ulcers of the leg, pulmonary tuberculosis, typhoid fever, and others. The results obtained were good.

CHLOROFORM IN TYPHOID FEVER.

In the treatment of typhoid fever, excellent results have been obtained by Stepp (*La Clinique,* Brux. Jan'y 15, 1891) with the internal administration of chloroform. The drug was given according to the following formula:

℞ Chloroform..... 1 gramme.
Water.....150 "

M. To be given in three doses, in the course of the twenty-four hours. The bottle should be shaken before using.

The influence of this treatment in the course of typhoid fever was certainly favorable. In the worst cases, insomnia and delirium, and the dryness of the mouth disappeared under the use of the remedy, while general amelioration was invariably observed. In from eight to ten days the fever diminished and convalescence began. In all the cases treated with chloroform the duration of the febrile period varied from nine to thirty days, eight being the minimum. The total amount of chloroform ingested to each patient varied from ten to twenty grammes. No untoward effects were ever observed in the course of the treatment. According to the author the favorable influence of chloroform in typhoid fever, is due to the germicide properties possessed by the drug. Recent researches show that the remedy passes through the circulation as chloroform, and as such is eliminated by the organism. In the second place, chloroform administered in the way and in the doses indicated above, acts as anæsthetic and thus aids to control excitability.

HYOSCINE IN MANIA AND INSOMNIA.

Malfilatre and Lemoine report in the *Gaz. Méd. de Paris* the result of a trial of hyoscine on some sixty-two patients, chiefly of the maniacal class (*Practitioner,* xxxvii, p. 321). The results obtained were very favorable. In the great majority of cases they found that they had either an immediate and continued hypnotic effect from very small (three to five-tenths cmm.) or moderate (1 cmm.) doses administered hypodermically, and in only a very were few larger doses required; and also that there did not appear to be such uncomfortable lasting after-symptoms as sometimes contra-indicate the employment of other hypnotics. These investigators feel justified in affirming that in hyoscine we have an excellent palliative in all conditions of insomnia with agitation, but they decline to commit themselves as regards its curative effects. Its inconveniences are the temporary intoxication it produces in some very sensitive individuals, and the necessity of steadily increasing the dose to produce the hypnotic action in some few others.—*The Dublin Journ. Med. Science.*

THE THERAPEUTIC USES OF EXALGINE.

The effects of this new remedy, exalgine or methylacetanilide, have been carefully studied by Desnos (*Bull. général de Therapeutique,* Feb. 15, 1891). After reviewing the literature of the subject, Desnos gives the results of his experience in the treatment of disease by the new drug.

Exalgine was tried in the treatment of affections essentially characterized by pain, particularly in facial neuralgias, due to lesion of the trigeminal, and even to those of the occipital nerve. Congestive neuralgias, due to cold or a rheumatic condition, usually yielded to moderate doses; but if relapses occurred, the medicament was continued for a long time in large doses. A case is reported of a woman suffering from neuralgia, in whom enucleation of the eyeball was not successful in relieving pain. She was given exalgine in doses of from 3 to 22½ grains, with the result that she was discharged cured in the course of thirteen days.

It was observed that the drug acted most favorably in neuralgias due to anæmia and syphilis. In diffused headaches and migraine, the results were negative or doubtful. In intercostal neuralgias the effects were generally satisfactory.

A persistent, very painful neuralgia of the brachial plexus was completely subdued by a dose of 22½ grains. In this case a pronounced tingling, which soon passed away, was experienced along the branches of the plexus. In neuralgias of the ileo-lumbar region, of a uterine origin, the drug did good; but relapses, due to the persistence of the lesion in the genital organs, only yielded to large doses.

Sciatic neuralgias were also checked by exalgine, one truly remarkable case being reported. The author has likewise obtained good results with the drug in the treatment of visceral neuralgias, the acute pains of locomotor ataxia, and has known exalgine to be of benefit in the pains of menstrual hysteralgia. A case of paralysis agitans, due to emotional causes, was cured by exalgine, and the drug was found of great service in certain cases of rheumatism.

In conclusion, Desnos considers exalgine a therapeutic agent of great value—an analgesic which is neither a hypnotic nor an antithermic in the proper sense of the word. To obtain the good effects of the drug, it should be given in full amounts. The usual dose is 3¾ grains, but 15 to 26 grains may be given without producing deleterious effects.—*Univ. Med. Mag.*

AGARICINE IN THE TREATMENT OF NIGHT SWEATS.

This drug has been used by Bocquillon (*Province Méd.*, Jan. 10, 1891) in the treatment of pulmonary phthisis. In these cases the remedy diminished the diarrhœa, lessened the cough and produced a more quiet sleep. Doses of from 5 to 8 milligrammes were given hypodermatically from 5 to 6 hours before the appearance of the sweats. Seifurt employs for hypodermatic use, the following solution:

℞

Agaricine.....0.05 grammes.
Absolute alcohol.....4.50 grammes.
Glycerine.....5.50 grammes.

M. This is a ½ per cent solution of which a syringefull can be given 5 hours before the appearance of the sweats.

THE THERAPEUTIC EFFECT OF STRYCHNINE IN CARDIAC AFFECTIONS.

The *Medicinisch-chirurgische Rundschau*, February 1st, has an extended notice of a recent paper by Professor Baldo Zaniboni, of Padua, on this subject. Zaniboni's article is based on a large number of clinical observations, with sphygmographic tracings, and appeared originally in the *Revista veneta*, Nos. 2 and 3, 1890. The following are his most important conclusions:

Strychnine is without question a very efficient exciter of cardiac activity. By its use the systolic impulse is strengthened, the diastole is prolonged, and attacks of arhythmia are cut short; subsequently the arterial tension is increased and the pulse-rate, if rapid, is slowed; if retarded, is accelerated. Acute dilatation and the dangers of heart failure, especially of the right side, are removed. Respiration becomes freer, and attacks of dyspnœa are completely relieved. Only in cases in which the nervous and muscular elements of the heart are no longer susceptible of stimulation does strychnine remain without effect. Œdema, even when it has resisted treatment with digitalis, disappears quickly, and there is free diuresis without the occurrence of albuminuria, such as follows the use of strophanthus. The bodily temperature is not noticeably affected. The appetite improves and the action of the bowels is regulated in consequence of increased persistalsis. The contractility of the arteries is heightened by the vaso-motor action of the drug. The hypodermic injection of strychnine is well borne, and with careful antisepsis causes no local reaction. Beginning with one-sixty-fifth of a grain, the dose may be increased to one-thirtieth of a grain three or four times a day, without producing subjective or objective disturbances. The treatment may be stopped abruptly, even when the largest doses are being given, without causing any unpleasant symptoms. The effect of the salt is seen very quickly (in about ten miuutes) after the injection, and lasts for several hours. Even after the long-continued use of strychnine no symptoms were noticed that pointed to any cumulative action of the drug.—*N. Y. Med. Jour.*

BRONCHITIS PRODUCED BY THE VAPORS OF PICRIC ACID.

A peculiar form of bronchitis produced by the vapors of picric acid is described by Regnault and Sarlet (*Annales d'hygiene*, March, 1891). The malady is characterized by paroxysms of dyspnœa, frequency of respirations, and of cough and the absence of a glairy expectoration at the end of the crisis. The paroxysms come during the day and also during the night. Death is rarely produced.

In a fatal case, observed by the authors, the patient's death was due to an intercurrent malady: *la grippe.* A chemical analysis showed the presence of picric acid in the urine, the blood and the liver. The patient, poisoned by the picric acid vapors, exhibited a condition of anæmia and a yellowish coloration of the skin, of the hairs on the surface of the body and of the parts, especially, mostly exposed to the toxic emanations. The diagnosis of the peculiar dyspnœa and asthma was easily made, especially after the analysis of the urine, which usually contained picric acid.

MEDICINE.

NEURASTHENIC STIGMATA.

Recent issues of the *Union Médicale* contain a résumé of Dr. Bouveret's lectures on neurasthenia. While the symptoms of this interesting disease are extremely varied and numerous, according to Dr. Bouveret's view there are certain distinct manifestations which are sufficiently constant to be called the stigmata of neurasthenia. These are headache, insomnia, muscular weakness, vertebral pain, atonic gastro-intestinal dyspepsia, to which are frequently added habitual dilatation of the pupil owing to feeble reaction to light, together with discoloration and objective and subjective coldness of the hands and feet.

While the headache is more or less persistent, the pain is not particularly severe, the sensation being more that of heaviness, fulness and constriction, as of a hand or cap pressing upon the scalp, giving rise to what Charcot calls the helmet symptom. In event of intense headache, which sometimes exists, it is circumscribed, may be limited to the forehead, one temple or both, to the occiput, or the back of the neck. Aching and weariness in the neck are common, and in themselves are rather good signs of neurasthenia. The neurasthenic headache is increased by work, intellectual effort, noise, and sudden emotion. During these exacerbations vertigo is not infrequent. True migraine may complicate this cephalalgia and render the condition doubly trying. Insomnia is of the persistent order, and is rebellious to treatment. It may be absent in women. In certain rare cases, irrespective of sex, the fatigue of work is followed by attacks of irresistible somnolence. Dreams are common, and more or less distressing. Sleep may come only toward morning, or it may visit the patient early in the night, leaving him to the horrors of wakeful visions after an hour or two. In either case the sufferer rises unrefreshed, in a condition of extreme weariness, without energy and without hope, and as thoroughly sapped as if he had been up all night.

Mental depression in neurasthenia expresses itself as exhaustion of all the mental faculties. There is loss of memory, of judgment, of will, inability to fix the attention for any length of time, and to resist sufficiently the influence of psychic impressions. Impairment of will is the keynote to the psychic state in neurasthenia. It is impossible for the patient to pursue the even tenor of his way. The character changes. The thousand and one petty annoyances of daily life are converted into so many excuses for irritability, anger, and exhibitions of bad temper. General weakness exists, and a notable diminution of muscular force is usually present. After slight emotion, moderate physical fatigue, sometimes without assignable cause, there will come a sudden feeling of profound prostration and complete loss of strength, together with painful fatigue in the calves, knees and thighs. Vertebral pain is almost as common as headache. It is a sensation of heat, burning, lassitude, and strain along the spine. This has favorite points of location: the seventh cervical vertebræ, the lumbar vertebræ, and the sacral region. It may exist in the coccyx alone.

There are two forms of neurasthenic gastro-intestinal atony. In the first, only functional disturbances appear. In the second, the patient emaciates, loses strength, and objective symptoms are present. Abdominal examination reveals prolapse and dilatation of the stomach, flabbiness of the anterior abdominal parietes, together with descent of the kidneys and liver in certain instances, completing the anatomical complexus that Glenard has described under the title of enteroptosis. There are cases, not so rare either, where, after the earliest developments of neurasthenia, the patient passes progressively and rapidly from functional gastro-intestinal atony to interoptosis of serious moment.

A chemical hypothesis to account for neurasthenic phenomena has recently been proposed by Professor Kowaleski, of Charkow, of which mention appears in the *American Journal of Insanity,* January, 1891. Acquired neurasthenia may be divided into two principal varieties: one where there is excessive mental strain or exertion without sufficient nourishment. The brain is starved with the rest of the body, and naturally fails to perform its functions. The other form of the disease is

found in those who lead lives of intense mental activity within a narrow field, and who have but little physical exercise. The tendency of modern civilization to specialism leads to the restricting of mental activity to a limited range of topics, tending to local exhaustion of the brain. This exhaustion may come about in spite of an abundant supply of food. In consequence of the sedentary lives led by persons engaged in intellectual pursuits, food may aggravate the evil, poisoning the brain by imperfectly assimilated material. Alcohol, tobacco, tea, and coffee taken to stimulate flagging energies, together with late hours to make good the losses of the day, serve to render bad matters worse. The congenital form of neurasthenia, when not connected with anatomical anomalies of the nervous system that can be demonstrated, must be considered due to defect of organization that conjecture may reasonably ascribe to its abnormal chemical constitution. In view of the frequent appearance of neurasthenia and allied disorders among children of drunkards, it seems probable that poisoning of the nervous system of the parent may result in defective chemical composition of the nerve-elements in the offspring, this being latter-day retribution following the eating of sour grapes by modern fathers.—*Med. Rec.*

GLYCOSURIA AND DIABETES.

Moritz (*Münchener med. Wochenschrift*, Jan. 6, 1891) considers it probable that grape sugar is present in normal urine from the fact that the characteristic reaction with phenolhydrocine can be demonstrated. There are a great many cases where grape sugar appears in the urine which are not real diabetes mellitus; this may be called simple glycosuria. This symptom is comparatively harmless in the absence of all the severe general symptoms—emaciation, loss of strength, thirst, furunculosis, etc. A combination of these general symptoms with sugar in the urine determines a diagnosis of diabetes mellitis, but it is not safe to exclude the disease in all cases where sugar appears without the general symptoms, for there are certain instances where a small amount of sugar constantly present in the urine is the only symptom until a sudden outbreak of a general character occurs.

It is impossible to fix upon any one symptom which distinguishes simple glycosuria from true diabetes mellitus, but simple glycosuria may be said to be an increase of the normal amount of sugar, which disappears with the cause, while diabetes mellitus is a true disease, chronic in nature, its characteristic being the persistence of the glycosuria. The author divides all cases into two groups—glycosuria occurring under pathological conditions, and glycosuria occuring under physiological conditions. He then quotes many pathological conditions give rise to glycosuria—injury to ihe floor of the fourth ventricle, extirpation of the pancreas, cirrhosis of the liver, and apoplexy, being among the number. Among the physiological conditions he considers the puerperium as the most import. Eighty per cent of all lying-in women have from ·8 per cent. to 1 per cent of sugar in the urine. The so-called alimentary form of glycosuria occurs after the ingestion of a large amount of sugar. Some authors consider that this tendency to excrete sugar shows a disposition toward diabetes mellitis. Where this tendency to glycosuria is noticed only after the ingestion of sugar it may be considered physiological, bnt where it is found after a meal of starchy foods it may be considered pathological.

For clinical purposes diabetes mellitus may be divided into a mild and a severe form. In the first the sugar is taken from the carbohydrates of the food; in the latter this is not the case. In suspected cases the urine should be examined some hours after a meal of carbohydrates with little or no sugar. If sugar is present in the urine a diagnosis of diabetes mellitus may be made; if it is absent the disease may be excluded. In certain cases where a large amount of urine of low specific gravity is excreted, it is necessary to examine the urine passed shortly after the meals, and not a specimen of the mixed urine.

The author considers the fermentation test the only entirely reliable one. He advises the following simple apparatus: A test-tube is filled with a mixture of urine and yeast and is stopped with a gum cork perforated with a U-shaped tube. Two control tubes are filled, one with normal urine and yeast, and another with the suspected urine with yeast, and a little sugar added. Care must be taken that the urine is not rendered antiseptic by the administration of salol or salicylic acid to the patient. If the urine contains sugar, carbonic acid gas will collect in the upper part of the tube. He advises the combination of this test with one of the reduction tests to make the diagnosis absolutely sure.—*Univ. Med. Mag.*

SURGERY.

INSTANCES OF FOREIGN BODIES LODGED IN THE BODY.

Francis L. Haynes. gives in the *Annals of Surgery* a collection of cases of this nature which is of much interest:

I. A TOOTH IN A BRONCHUS PRODUCES A PULMONARY ABSCESS. IT IS EXPELLED SPONTANEOUSLY AND THE PATIENT RECOVERS.

A middle-aged man presented all the symptoms of a copiously suppurating cavity in the apex of the right lung, and was supposed to be afflicted with consumption. After I had attended him for three months, during which he improved greatly, he expelled a tooth from the lung during a severe paroxysm of coughing. Recovery from all symptoms of pulmonary disease was rapid and complete.

A minute cross-examination now showed for the first time that, one year previously, the man had, as he supposed, swallowed a tooth immediately after its extraction, and that his illness had dated from that time.

II. A PIECE OF SHEEP'S VERTEBRA IN THE LUNG PRODUCES AN ABSCESS WHICH, AFTER ONE YEAR, RESULTS IN DEATH.

A woman, æt. 50, while hastily swallowing some soup, felt that a hard substance had passed into the air passages. An immense cavity rapidly developed in the lower lobe of the right lung. After six months, during a severe paroxysm of coughing, a large piece of the body of a sheep's vertebra, the shape of a maltese cross (measuring 1 by ½ by ¼ inch) was expelled. The cavity, however, continued to suppurate and the woman died about a year after the date of the accident. Prof. S. D. Gross examined this case but did not suggest any operative procedure.

III. A BEAN IN THE AIR PASSAGES CAUSES SPEEDY DEATH.

A boy, æt. 5, while holding some beans in his mouth, suddenly exclaimed that one had "gone down the wrong way." Suffocative symptoms were at once noted and continued until death 36 hours afterward. Physical examination showed that no air entered the right lung. The parents would not permit an operation.

IV. REMOVAL OF THE TIP OF A HARD RUBBER SOUND FROM THE PREGNANT UTERUS.

A healthy woman, two months pregnant, while inserting a hard rubber sound into the uterus, broke off a piece two inches long, which remained in the organ. Dr. E. A. Follansbee was consulted, and asked me to assist in the management of the case. With the metallic sound the body could readily be felt, but it lay across the uterus, and its ends seemed to be embedded in the mucosa; it could not be removed until the cervix was dilated, which was at once accomplished by Goodell's dilator, under ether narcosis. The body was now readily removed by a slender pedicel forceps guided by the finger. As the membranes had been ruptured by the patient's probing, the uterus was emptied by the finger, and washed out.

V. A GLASS DISC REMAINS IN THE VAGINA FOR TEN YEARS, CAUSING A STRICTURE, WHICH REQUIRES TO BE INCISED, THAT THE DISC MAY BE REMOVED.

A woman, æt. 60, had worn a glass disc in the vagina continuously, for the relief of prolapsus, for ten years. As it finally produced a purulent discharge she asked me to remove it. One and a half inch up the vagina a stricture barely admitting the index tip was felt. It was incised in the median line posteriorly and a disc two inches in diameter removed. Unfortunately hæmostasis was carelessly made, and the patient bled for two days before she thought it worth her while to send for me. It took two months to cure the resulting anæmia. After six months the patient reported that she was well and that the prolapsus had not recurred.

VI. A CHILD IS TREATED FOR NASAL CATARRH FOR FOUR YEARS, AND RECOVERS ON THE REMOVAL OF A SHOE BUTTON FROM THE NOSE.

A girl, æt. 8, had received much unavailing treatment for the relief of a profuse purulent discharge from the right nostril. On inserting a probe I distinctly felt a smooth hard body buried in a mass of rotton tissue between the inferior and middle turbinated bones about one inch behind the tip of the nose. The body, which was supposed to be dead bone, was easily removed, and proved to be an ordinary gaiter button. Recovery was rapid and complete.

FRACTURE OF THE LARYNX.

An interesting case of fracture of the larynx is reported by Dr. Sokolowski, in the *Centralblatt für die med. Wissenschaften*, April 11, 1891. The patient was a mill-hand, twenty years old, who was caught in the driving wheel of a machine, by her apron, which was fastened about her neck, and

thrown some distance. She immediately experienced severe pain in the larynx, difficulty in breathing, and expectorated a considerable quantity of blood. The neck was greatly swollen and crepitation over the larynx was distinctly felt, and a considerable depression of the cartilage on the left side to be seen. The laryngoscope showed two inflamed swellings immediately below the epiglottis. Tracheotomy being indicated, an incision over the larynx was made and the fracture found. One fragment of cartilage was pushed into the windpipe. This was removed, and breathing at once became easy. Still the extent of the fracture was such that a tube was inserted and left in place. The patient ultimately recovered.

SUFFOCATING GOITRE.

The following interesting case of extirpation of a goitre, is reported in the *Revue de Laryngologié, d'Otolog. et de Rhinolog.*, May 1, 1891. The patient was an Italian, seventeen years old, and Dr. Arthur Berti, of Modène, the operator. The man came from a district where goitre was very rare. His previous family histories were negative. Up to his thirteenth year he had always enjoyed good health. At this time a tumor appeared, of about the size of a small nut, a little to the right of the median line of the throat. The growth was freely movable, hard, and indolent. Soon after the tumor began to rapidly increase in size, until, when the patient presented himself at the hospital, it had attained the size of a large orange. Respiration was difficult and deglutition impossible. Extirpation was performed only with great difficulty, as the growth completely surrounded the trachea, nevertheless, its entire removal was effected. His wound healed up within six days, and no subsequent trouble was experienced by the patient.

GONORRHŒAL EPIDIDYMITIS.

Drs. Martin and A. C. Wood, in *The University Medical Magazine* in a study of this, the most frequent complication of gonorrhœa, reach the following conclusions:

1. Gonorrhœal epididymitis occurs most frequently in those who have received no treatment for the original urethritis. Its outbreak is frequently determined by violent or long-continued physical exertion, or by venereal excess.

2. The resultant induration of a gonorrhœal epididymitis does not cause obliteration of the convoluted duct in the majority of cases. Statistics on this point are misleading, from the fact that it is practically only the few sterile patients who are subsequently observed by surgeons, and hence these form the greater number of the reported tabulations.

Of four cases of double epididymitis observed by us, not under treatment for sterility, there was an abundant discharge of spermatozoa in three.

3. Unilateral epididymitis may, in exceptional cases, cause permanent sterility. During the acute attack very few spermatozoa are found in the semen.

4. Obliteration of the duct does not cause atrophy of the testicle.

5. Pain, tenderness and swelling in the groin, dependent on funiculitis, practically always precede gonorrhœal epididymitis. Prompt treatment at this stage may abort the inflammation of the epididymus.

6. The development of gonorrhœal epididymitis is, in a great measure, avoided by the use of antiseptics by the mouth, and the application of a suspensory bandage to the scrotum.

7. The pain and disability usually attendant on gonorrhœal epididymitis are promptly allayed by puncture, or aspiration of the serous exudate contained in the tunica vaginalis and the cellular tissue placed behind and above the epididymus, followed by the application to the scrotum of a thick layer of cotton, over which is placed a Mackintosh suspensory, so made that it presses the inflamed organ upward against the pubes, and, by means of lacings at the side, can be so drawn in that uniform lateral support is secured. Punctures are necessary only in the most acute cases.

8. The subsequent induration after the acute stage is most quickly resolved by a continuance of the dressing above described, together with the local application of belladonna and mercury ointment, and the internal administration of iodide of potassium.

GYNÆCOLOGY.

CANCER OF THE BREAST TREATED BY INJECTION OF METHYL-VIOLET.

Dr. Edw. T. Grün, in the *Brit. Med. Jour.* writes: The patient, whose case is described below, presented herself suffering from a well-marked circumscribed indurated tumor of the breast, about the size of a small egg. The case was considered a particularly suitable one for testing the efficacy

of Dr. Mosetig's treatment by injection of methyl-violet.

The treatment having been explained to the patient, her consent was readily obtained, and a course of twenty injections was prescribed. This treatment was commenced with a dose of 10 minims of 1 part of methyl-violet in 300 parts sterilized water; administered February 7th, 1891. The injections were given daily. The first ten injections produced no pain and no inflammation of the breast, but, after the tenth injection, a slight redness of the skin became apparent, which increased after each injection. On the fifteenth day of treatment some suppuration of the breast tissue was present, masking, to a great extent, the tumor. The injections were still continued. After the twentieth injection, on careful examination, the tumor being still present, it was decided to remove the breast in the ordinary manner.

The operation was performed by Dr. Hugh Fenton, with strict aseptic precautions, after the manner of Dr. Edgar Kurz, of Florence, described in the *Deutsche medicinische Wochenschrift* of November 20th, 1890, and, although considerable suppuration was present in the breast, the wound healed by first intention at the end of seven days, the only application to the breast having been dry Gamgee tissue, carefully sterilized previous to the operation in the hot air sterilizer, as were all the instruments used in the operation, no carbolic acid or iodoform being used at any time during or after the operation.

The breast, on examination after removal, was found to contain a typical tumor of the scirrhous cancer variety. The growth presented no alteration that could be attributed to the methyl-violet, even when examined, after hardening and staining, by very high microscopic power, such as the $\frac{1}{12}$th and $\frac{1}{18}$th oil emersion. No degeneration of the cancer structure could be observed around the growth. Considerable suppuration of the glandular tissue of the breast had taken place, which, no doubt, under ordinary antiseptic dressing, would have considerably retarded pimary union. The result of the treatment by methyl-violet must, in this case, be regarded as purely negative. The rapid healing of the wound speaks greatly in favor of the aseptic sterilized dressing, now so largely adopted on the Continent with such good results, Dr. Kurtz giving a mortality of 2 in 169 cases of operations, of amputations, resections, laparotomies for perforation in typhoid fever, and other major operations.

WOUNDS OF THE URETERS IN LAPAROTOMIES.

During the last session of the French Congress of Surgery, Dr. Pozzi read a paper on wounds of the ureters in laparotomies. Pozzi has succeeded in finding the histories of several cases, including one observed by Gusseron and one occurring in his own experience.

If the wound of the ureter is lateral it is possible to make a suture. In one case thus treated the patient died. In another reported by Gusseron recovery followed the operation. Wounds of the ureters are most likely to be produced during the removal of retro-peritoneal cysts.

The case reported by Pozzi was that of a woman fifty-three years old, with an intraligamentous cyst. The tumor had been of rapid growth, and the patient's general condition was very poor. Laparotomy was performed, and revealed a large red tumor with a rough surface. The tumor was enucleated with great difficulty, being firmly adherent. During the course of the operation one of the ureters, which was attached to the tumor, was cut through. The operation was completed, a Mickulicz tampon being used and the end of the ureter sutured to the abdominal wound. Subsequently, nephrectomy was performed, and the patient made a good recovery.

OBSTETRICS.

OVARIAN PREGNANCY.

At a recent meeting of the Royal Medical Society of Vienna, reported in the *Wiener Med. Presse*, April 12, 1891, Dr. Herzfeld told of an interesting case of ovarian pregnancy. The patient was a multipara, thirty-three years old, and on March 12, gave birth to a child at the normal end of gestation. After delivery the abdomen remained distended, and a second fœtus was clearly definable above the empty womb. The patient did not come into the hospital until the fœtus was dead. Dr. Herzfeld performed laparotomy and removed the fœtus with ease, it being attached to the adnexa of the uterus by a small pedicle. The question of tubal pregnancy could be set aside as the right tube could be traced in its entire length. The uterus was empty and the left adnexa normal. An anatomical examination proved the case to be one of ovarian pregnancy. This case is not only of interest because it occurred in conjunction with a normal pregnancy, but especially so as it

definitely proves the possibility of a pure ovarian pregnancy, and because it continued until full term.

EPILEPSY FROM A DEPRESSED FRACTURE PRODUCED WITH THE OBSTETRIC FORCEPS.

A boy, sixteen years old, came under Mr. Lane's care for epilepsy (*Lancet*, Jan. 17, 1891). He had been subject to these fits for two years, or from the age of fourteen years. When he was about to have a fit he noticed a twitching at the junction of the middle and lower thirds of the leg on its outer aspect, and his foot and knee then jerked in a manner that resembled ankle clonus and knee-jerk. A pain then ran up the outer side of the leg and thigh, through the left side of the trunk to the arm, then to the left side of the face, and, when the fit was severe, to the right arm.

On examination, a groove three inches and a quarter long was found on the right side of the head, extending from an inch behind the coronal suture to about the same distance in front of the lambdoid suture. Its anterior extremity was vertically above the external auditory meatus, and its lower limit reached just below the temporal ridge. From this it extended downward and backward toward the external occipital protuberance. The left arm was the smaller and weaker, its muscles were less firm and its movements were distinctly clumsy. There was no difference in the appearance of the muscles of the legs, but the patient had never had the same confidence in the left that he had in the right leg. By simply raising the left foot to a right angle, a very rapid clonus could be obtained. By using more force a clonus could be produced in the right ankle. The plantar, knee, and abdominal reflexes were exaggerated on both sides, but most decidedly on the left. The depression on the right side of his skull was said to have been noticed immediately after birth, the delivery having been effected with the forceps with much difficulty. It had become less conspicuous as he had grown older. The depressed area of bone was finally removed. It was found to be very thin and vascular, and appeared to encroach but little on the cranial cavity. The dura and subjacent brain appeared healthy. The wound healed by primary union. Since the operation, fits have occurred at longer intervals and are much slighter. He has gained power in the left arm and leg, and never suffers from headache, and has become mentally much brighter.

PÆDIATRICS.

OBSTETRICAL PARALYSIS IN THE NEWBORN.

Not a year passes but what several cases of paralysis, dating from birth, are brought before the various surgical clinics of the continent. Most of these cases are children suffering from paralysis of the upper extremities, and are the results of injuries sustained during dfficult labors.

These paralyses, which are directly due to obstetrical proceedures, such as version, the use of forceps, traction on the limbs, etc., have been recognized by the profession for some time. Dr. Comby, of the *Société médicale des hopitaux*, has been recently engaged in investigating their origin and prognosis, and a report of his work is given in the *Revue Médicale*, March, 1891. The facial paralysis, he claims, is due to compression by the forceps; likewise, frequently, the paralysis of the lower extremities. Rarely are the latter caused by injury to the spinal column or the cord.

The paralysis of the upper extremities, called "radiculary paralysis" by Comby, is directly due to a stretching or compression of the brachial plexus, caused either by application of the forceps, version, or hooking the shoulders of the fœtus, by means of the operator's finger or by an instrument.

Erb has demonstrated that all these violences cause a lesion of the fifth and sixth cervical nerves; nearly always the paralyses occur in the same muscles: the deltoid, the sub-scapular, the biceps, and the coracobrachial. The radicular paralysis may, however, be complete and include all the muscles of the upper extremities.

The prognosis of such paralyses is always serious. Duchesne holds that unless active treatment is instituted very early, a hopeful prognosis cannot be entertained; and the child, which in other respects may be strong and healthy, will surely remain a cripple.

According to Duchesne, the treatment includes Faradisation—applications of the current being made two or three times a day, and continued for five or ten minutes—also the application of the continuous current; and finally these means may be augmented by massage, stimulating frictions with turpentine, and salt baths. Dr. Goffroy recommends strongly electrization by means of the galvanic current, not in a continuous current, but interrupted. For the ultimate success of the case, it is, of course, of utmost necessity that the treat-

ment should be instituted as early as possible, and most carefully regulated.

A CASE OF TRISMUS NEONATORUM TREATED WITH SULPHONAL.

Dr. Julius Berenyi (*Pester mediz.-chirurg. Presse*, No. 7, 1891; *Therapeut. Monatsh.*, March, 1891) reports the case of a child, eight days old, who had tetanus on the fifth day after birth. On examination he found the internal organs normal, the pulse 148, the respirations 50 and quiet. The paroxysms were initiated by crying fits and great restlessness. The skin assumed a bluish color, and around the root of the nose the integument was thrown into thick folds. The nostrils became distended, the buccinators were rigid, the mouth was slightly opened, but would not admit the tip of the little finger. The abdominal wall was hard and tense, the upper extremities were crossed in a flexed position over the chest, the thumbs were spasmodically flexed inward, the vertebral column was perfectly rigid. From nine o'clock in the morning to two o'clock in the afternoon the little patient had five attacks, of which the fourth lasted an hour. Berenyi administered twenty centigrammes (3 grains) of sulphonal in an enema, and also gave the drug by the mouth. After the fifth attack, which was less intense than the others, the child began to take the breast. On the same day three attacks of diminished severity occurred. On the following day the paroxysms became less frequent and intense, and on the sixth day of treatment had disappeared completely. Altogether, ten grammes of sulphonal were employed, without the occurrence of somnolence or disagreeable after-effects.

HYGIENE.

ON THE RELATION OF ATMOSPHERIC ELECTRICITY, MAGNETIC STORMS, AND WEATHER ELEMENTS TO A CASE OF TRAUMATIC NEURALGIA.

R. Catlin, U. S. Army, writes in the *Medical News*: In the relationship of atmospheric electricity to pain, it is shown that by a comparison of 120 daily curves taken on neuralgia periods with the mean of the same number for *ten consecutive days* of each month, pain seeks identity with both lower positive curves and with the negative, and with fluctuations of great amplitude.

For the influence of May storms on pain the maximum auroral period of 1882–83 was selected; of this period, seven of the greatest magnetic storms were chosen. Accompanying each was pain, and in the majority of cases pain of unusual intensity prevailed. The great storm of November, 1882, the greatest of which we have a record, shows the relationship to be unequivocal. In the other cases the magnetic storm was coincident with other causes, which may or may not have had something to do with pain, but in four cases no dry or wet cyclone was in any way connected with the trouble.

The comparison of the weather elements —such as pressure, temperature, force of wind, humidity, relative and absolute, days of rain, depth of rain, hours of sunshine, number of storms, and ozone—with pain—covers a period in no case of less than five years. Of these the increasing temperature curve, the hours of sunshine curve, and the absolute vapor curve, operate to diminish pain, while all the others are identified more or less with pain. In the monthly products for fourteen years it appears that the "depth of rain," ozone, and "number of days of rain," in this order, but almost equally, constituted the best standards for pain measurement. By generalizing on the extremes through all these years, by taking the twelve months of greatest pain and the twelve of least pain, the above conclusions are verified, and the law stated in general terms, as follows:

Maximum pain bears a direct proportion to storm frequency, and an inverse proportion to temperature and elastic force of vapor; and minimum pain bears an inverse proportion to storm frequency, and a direct to temperature and elastic force of vapor; while depth of rain accompanies the number of storms and maximum pain. Charts of *relative storm frequency* and *geographical pain* charts are thus related.

What are known as "*spells*," or "*types*," of weather, lasting from one to three weeks, probably due to the relative position of the great anti-cyclone areas, having their influence on pain condition. This fact was recognized early in the history of this case, in 1869. Increased amount and intensity of pain accompany these "spells," particularly at their beginnings. Covering a period of fifteen years the *relative ratios of the monthly products of pain* were as follows: February, 176; March, 175; January, 174; December, 168; November, 164; April, 161; May, 160; July, 159; June, 154; September, 153; and October, 153. The ratios were determined by dividing the total number of hours of neuralgia of each month by the

total number of hours in the month for the whole period of fifteen years.

Perhaps the most difficult and complex part of the problem is in offering an explanation of the diurnal fluctuations of pain.

The record of hourly beginnings of pain covers a period of more than eighteen years; and the curve of the record of hourly beginnings of storms and the amount of rain of each covers a period of sixteen years.

The daily pain curve exhibits 3 pain maxima; the first at 11 A. M., the second at 2 P. M., and the third at 7 P. M. The part of the curve at 6, 7, and 8 A. M. has almost an inverse counterpart in 8, 9, and 10 P. M., but in the curve from 9 A. M. to 7 P. M., there is a very important minimum at 12 M. and 1 P. M., then a subordinate minimum at 3 P. M., very like that at 10 A. M., followed at 5 and 6 P. M. by a distinct minimum.

By placing on the pain curve the storm curves for the sixteen-year period, it becomes manifest that while the absolute values of the rain depths and number of storms on the pain curve do not show a full correspondence, it is, however, clear at once that there is a relative value between the two and the pain.

In all the discussions of this subject to this time, only instrumental records, such as synoptic charts, thermograms, etc., have been brought into use, but it is clear that the physical effects produced by the temperature on the southeast side of a cyclone is very different from the same record-temperature on the west or the northwest side.

It is found that the eastern edge of the neuralgic cresent lies more than six hundred miles, or about twenty-three hours to the east of the centre of the "lows," but no two cyclones or rain conditions are exactly alike, and have different kinds of rain, and when we consider that there are two atmospheres—one of a dry, gaseous air, and another one distinct, of aqueous vapor, with the latter never thoroughly intermixed with the former, and never in a state of equilibrium—we partially realize how impossible it is in any given storm to get a complete record by instruments, or of those which are the best pain-producers, for without apparent instrumental cause they vary much in this respect.

No local hygrometric reading can give anything more than a vague approximation of the quantity of vapor or its mixture in a vertical column of air.

A typical neuralgic atmosphere, anticipating a cyclone, may be a dry air with a diminishing light, variable wind, and a pale, delicate, bluish whiteness in the atmosphere, more marked toward the horizon, and in the first stage more marked in the western horizon. The sickly whiteness may increase for from twenty to sixty hours, with an increasing discomfort when exposed to the peculiarly penetrating power of the sun's rays, but during all this typical condition there is nothing which has measured the changing aspect of the air, nor its changing condition of heat permeability, nor the absolute vapor, except at the surface, nor the distinctive character of the cyclone heat in the southeast quadrant, nor the direction of the upper and cross currents of wind, nor, above all, the modifications of the diurnal and "semi-diurnal" effect superimposed on the cyclone movement. It therefore seems important, in studying the hourly phases of pain, that meteorological charts should be supplemented by a descriptive narration to complete the record, and a closer study of the effect of diurnal change on weather.

HYGIENE IN FRANCE.

Recently the French Chamber of Deputies have considered a general law governing workers in factories, child labor, etc. M. de Mun proposed an amendment providing that women should not be allowed to work the first four weeks after confinement. The proposition created a lively discussion, the general tenor of which was to the effect that the private life of citizens should not be interfered with to the extent proposed, and that the fixing of an arbitrary limit of four weeks was not wise, as many would be able to be at work long before that time, while others would be incapacitated far beyond the limit. One member proposed that compensation by the State be given to the extent of one franc per day. The amendment was finally tabled by a decisive vote.—*Le Bulletin Médicale.*

MEDICAL CHEMISTRY

PRESERVATION OF HYDROGEN PEROXIDE.

For this purpose, Kingzett recommends the addition of a small amount of ether. Experiments conducted by the author show that pure hydrogen peroxide lost, in twenty-eight days, ten per cent.; in ninety-eight days, 27.4 per cent.; in two hundred days, thirty-nine per cent.; and in four hundred and ninety days, 89.2 per cent. The addition of sulphuric acid reduced these figures to 9, 23, 27½, and 68.3, respectively.

Alcohol reduced them to 1, 7, 4, 7.4, and 22.8, respectively, while ether still further reduced them, showing a loss of the peroxide in the times mentioned of 0, 1.3, 2.4, and 15.9, respectively.—*Med. Rec.*

NEW REACTION OF HYDROCHLORATE OF COCAINE.

M. Schell, student of pharmacy at Mulhouse, states, in the *Journal de Pharmacie d'Alsace Lorraine*, that if a minute quantity of a mixture of calomel and hydrochlorate of cocaine be moistened with distilled water a deep grayish coloration at once takes place. Care must be taken to avoid too great a quantity of water. No other alkaloidal salt gives this reaction, though if free atropine be heated with calomel and water to about 212°F. a black or blackish coloration ensues. The same result is obtained when a mixture of calomel and atropine is treated with very dilute alcohol. It is rather remarkable that cocaine (the base) in the one case, and the salts of atropine in the other, do not yield the results above mentioned.—*Nat. Druggist.*

TO DETECT COPPER COLORING MATTER IN TEA.

Sometimes worthless and exhausted tea-leaves are restored to their natural color and made to look like a superior article of green tea by coloring with copper or drying on copper plates. The addition of a little aqua ammoniæ to an infusion of tea thus colored will at once produce a blue color, more or less intense, according to the amount of copper present. The presence of copper coloring matter in pickles, preserved vegetables, etc., may be similarly detected.—*Nat. Drug.*

THE ALKALINITY OF THE BLOOD WHEN CONCENTRATED BY THE ACTION OF LARGE DOSES OF SODIC SULPHATE.

J. Swiatecki (Hoppe-Seyler's *Zeitschr. f. physiol. Chem.*, November, 1890) discusses this question. In 1850, C. Schmidt made the observation that in the algid stage of cholera the blood loses its alkalinity so markedly that in many instances it may even redden blue litmus paper—an observation that has often since been confirmed, as, for example, by the French Commission during the cholera in Egypt in 1883. Mya and Tassinari, who have investigated the different diseased processes which affect the alkalinity of the blood, have also studied its behavior under the influence of certain purgatives, such as infusion of senna, magnesia, and sodic sulphate, but without obtaining any positive results. The author accordingly pursued in the University of Warsaw a series of researches upon dogs with Glauber's salts, and as the result of them he concludes that the alkalinity of the blood increases when its specific gravity is raised by means of large doses of these salts; that this rise can be explained by the increased transudation of acids, as well as alkalies, from the blood into the intestine in accordance with the laws of osmose; and that the attempt to explain the increased alkalinity after the use of mineral waters exclusively through the passage of basic salts out of the intestine into the blood is not satisfactory.

NEWS AND MISCELLANY.

TUBERCLE BACILLI AT THE POINT OF INFECTION.

By inoculation on guinea-pigs and rabbits, Tangl has established (*Monatsh f. prakt. Derm.*, No. 4, February, 1891) the fact that tubercle bacilli cannot penetrate the body without producing tuberculous changes at the point of entry. He infers, therefore, that in primary tuberculosis of the lymphatic glands, or of the bones, if after even a considerable time there is no tuberculous change externally, the tuberculosis could not have been produced by external infection.—*Brit. Med. Jour.*

IMPORTANT IMPROVEMENT IN MICROSCOPIC LENSES.

It is stated that an immense improvement has recently been effected in the manufacture of glass for optical instruments by means of the addition to the ordinary materials of phosphorus and chlorine, which in some as yet unexplained way cause the glass to be very much more transparent, and enable it to receive a much higher degree of polish than any optical glass hitherto manufactured. Thus microscopes can be made which will render objects of the diameter of only the one-eighth millionth of a millimeter visible, whereas with the best instruments now in use the diameter of the smallest object that can be seen is one-sixteenth thousandth of a millimeter.

Clinical Lecture.

THE ETIOLOGY AND THERAPY OF WEAK LABOR IN PRIMAPARÆ OF ADVANCED AGE.

BY ERNST BÖRNER, M. D.,

PROFESSOR OF OBSTETRICS, UNIVERSITY OF GRAZ.

Gentlemen:—The subject of to-day's lecture, namely, the Etiology and Therapy of Weak Labor in Elderly Primaparæ, is one that is but very meagerly dealt with in the text-books. Only a few monographs of very recent date show that this subject has received any attention or study at the hands of specialists.

During the last summer, cases have been brought to this clinic, that have forced upon us the study of labor and confinement in primaparæ of advanced age, and it is high time that we should have a thorough understanding of the subject. Before going into the special subject under consideration, let me call to your mind the characteristic peculiarities, acknowledged by other observers, to be found in the confinement of elderly primaparæ. The majority of authors agree on many points, and a résumé of their opinions is, therefore, not difficult.

It is of primary importance to fix the dividing line between what may be justly termed young or old primaparæ. Ahlfeld places this age at thirty-two years, being—as he expresses it—the middle of the "ovulation-period" (15–50 years). Hecker is of the opinion that fifty years of age does not constitute the average age for "change of life" but is too old, and I agree with him. He, as well as Cohenstein, Rumpe, Steinmann, and other writers, take the age of thirty as the dividing line. Glancing at the tabulated records of various observers, we find that Cohnstein reports his observations at the parturition of 393 old primaparæ, Ahlfeld, 102, Hecker, 422, Rumpe, 100, Steinmann, 645, and it is from the results of these observations that we will form our résumé.

It will be of interest to you to know that Cohnstein reports the cases of women becoming primaparæ at the advanced age of fifty years; while the oldest primaparæ on record is one reported by Steinmann, the patient's age being fifty-two. The recorded observations, however, show that child-birth rarely occurs, for the first time, in women over forty years of age. The influences of a late appearance of menstruation upon late conception, the course of pregnancy, and peculiarities in parturition, in the sex of the fœtus, and in the lying-in period, are questions which are answered similarly by the majority of observers. The following table, compiled by Hecker, showing the age of the appearance of the menses in a number of primaparæ, speaks for itself:

In 39	cases	menstruation	began	at 20.
" 14	"	"	"	" 21.
" 13	"	"	"	" 22.
" 3	"	"	"	" 23.
" 4	"	"	"	" 24.
" 3	"	"	"	" 25.
" 1	"	"	"	" 26.

Late sexual development is, therefore, according to Hecker, the principal factor of late parturition.

Regarding the causes of delayed conception, Rumpe, while agreeing with Hecker in the importance of retarded sexual development, recognizes also three other possible causes. First, and very naturally, delayed cohabitation, until a late period of life; second, a hindrance to conception by some local disease, for which a suitable treatment should be instituted; third, a hindrance to conception caused by some unrecognized trouble or ailment, which, after years of cohabitation, yields voluntarily to conception. Such local anomalies have been reported by Cohnstein, and include rigidity of the vagina and of the vaginal entrance, rigidity of the *orificium externum*, closure of the external orifice resulting from long continued catarrh, and fibroids or sarcoma

of the uterus. He concludes, that pathological changes in the vaginal orifice, the vagina, or the external os, which prevent, or render difficult the accomplishment of coitus, or render the introduction of the seminal fluid into the uterus difficult, are among the most frequent causes of sterility. For a time also, it was erroneously held that a narrow pelvis should be considered one of the etiological causes of late conception. This, however, is totally unwarrantable. Regarding the peculiarities following the course of pregnancy in old primaparæ, Winckel has called attention to their predisposition to kidney troubles.

The researches of Deventer, Dionis, v. Siebold, Wigand and Michaelis, show that the rigidity of the sexual organs in old primaparæ, cause increased difficulty in childbirth, and result frequently in lacerations of the perinenum. E. v. Siebold has observed repeatedly delayed and painful labor, and considerable trouble in passing the afterbirth, owing to the weakness of the uterine contractions. Mauriceau speaks of difficulties occurring from the position of the os coccygis, and Neubeck, of the unyieldingness of the pelvic cartilages generally. The text book of Nægele-Grenser speaks of the inclination of old primaparæ to eclamptic convulsions. Valenta's experiences have shown him that in these cases a change of the fœtal condition very frequently occurs during the last month of pregnancy, causing a premature rupture of the bag of waters. This, he asserts, occurs with great frequency in primaparæ between the ages of thirty-six and forty years. Hecker calls attention to the frequency of extra-uterine pregnancy.

In connection with this brief historical résumé, it will be well to go a little deeper into the subject. The principal characteristic, acknowledged by the authors mentioned in the first part of this lecture, is the *weakness of labor* in old primaparæ. This weakness and tardiness of the contractions, may proceed throughout the entire course of labor, or else may show itself as a secondary symptom, the initiatory labor having been normal.

Curiously enough, this weakness of labor is accompanied by an utter disproportionate amount of pain, this being frequently of an agonizing nature. These convulsive pains occur most severely in cases when there has been a premature flow of the amniotic fluid, the os remaining hard and unyielding.

Rigidity of the soft parts in general is another factor, acknowledged by nearly all observers. Rigidity of the cervix tends to give trouble, and lacerations of the cervix occur frequently.

I have already spoken of the frequency of a premature rupture of the amniotic sac. Cohnstein observed this in over eleven per cent. of his cases.

All these unnatural conditions very naturally tend to produce a tedious course of labor for old primaparæ, and this may be regarded as an almost inflexible rule. This tediousness is especially marked during the "dilatory stage," while the "expulsion stage," is generally hastened by instrumental interference. Finally, also, the "afterbirth stage" is generally delayed; Rumpe's cases showing that tediousness in this stage of parturition occurs in 10 per cent. of primaparæ.

Bidder claims that the average duration of labor in primaparæ is 17.8 hours, while Ahlfeld holds thta 20.8 hours is a just average. Beumer and Peiper have found that the average duration of labor in old primaparæ is 25 hours, and Ahlfeld claims that it is 27.6 hours. Regarding the use of instruments, the general opinion is that, in old primaparæ, forceps will be used five times as frequently as in general cases. Operative interference for the removal of the afterbirth is also frequently necessitated; Cohnstein reports 26 cases in which he was compelled to use instruments in the removal of an adherent placenta, and Hecker reports 15 similar cases.

Another point, on which all writers on this subject seem to agree, is the frequent occurrence of puerperal eclampsia. Another frequent complication is post-partum hæmorrhage, caused either by atony of the uterus, adherent or retained placenta.

I have thus briefly given you the chief characteristics acknowledged to be of frequent occurrence in old primaparæ, but before leaving this chapter of peculiarities, must not fail to call your attention to one more, and one which, if met with, is likely to cause grave fears on the part of the obstetrician. When we have indications for the use of the forceps in these cases, we not only find a weak fœtal pulse, but very frequently also an abnormal weakness, and exhaustion of the patient. In two cases reported by Rumpe, death, which occurred during labor, could only be attributed to exhaustion. One of these cases was that of a primapara, age 35, who died after 60 hours of weak labor, and the other who died after 24 hours of labor, her age being 43 years. On the other hand, Ahlfeld reports 9 cases in which the patients evinced great excite-

ment, which gradually increased to a violent delirium. This, Ahlfeld claims, is due to an abnormal excitability of the nervous system, caused by the long and painful labor. I hold it to be of great importance to watch most carefully for these signs of nervous depression or excitability.

The number of still-born infants is, on an average, far greater in old primaparæ than in other parturitants. This is frequently caused by asphyxia of the fœtus, and this in turn, due to the tedious birth.

An interesting fact is that the number of male infants born by old primaparæ, far out-numbers the number of female infants. Finally, complications, and even death, during the lying-in period, are more frequently met with in old primaparæ than in others.

While experience has taught us the existence of these various complications, yet our scientific knowledge is still unable to definitely give the etiology of these symptoms, but in my opinion, these questions can still be answered by means of the results of extended personal experiences. The history of a case which I intend calling your attention to to-day, is calculated to throw light upon, at least, one of these questions viz., the significance of the different grades of modified labor in old primaparæ and its possible significance.

The history of the case is briefly as follows: The patient, Mrs. H., was a primapara, 35 years old, and of healthy parentage. Her family history is good. The patient herself, was a healthy child, and menstruated at the age of 12 years. During her married life she was always strong, healthy, and a good walker. Three years previously she had a slight increase of menstruation, and between the periods, she passed a slimy secretion from the vagina. Upon examination, I found a slight papillary erosion around the external orifice, and a slight hypertrophy of the anterior lip, which occasioned some contraction of the vaginal orifice. The hypertrophy was excised, the erosion subjected to the usual treatment and the patient soon recovered completely.

After her recovery, the patient shortly became pregnant for the first time during her married life. Pregnancy proceeded normally, and on December 24, the first fœtal movements were felt. At the end of March, I took the measurement of the pelvis and found it normal. In the middle of April the fœtal head was in the lower pelvis. According to my calculations the birth should have taken place about the first of May, but on the twenty-fifth of April, uterine contractions were felt, and the bag of waters broke. The fœtal head was well down in the pelvis, in the second occipital position. The fœtal heart was distinctly audible on the right side. The pains gradually increased, and were, to all appearance, normal.

During the entire day following (April 26), light labor continued, without producing any effect upon the position of the fœtus or dilating the cervix. The patient is up and about. April 27, the fœtal head still lower, but the cervix only dilated to the size of a finger. April 28, the condition unchanged, except that the contractions are becoming more and more painful, and a "sawing" pain appeared in the small of the back. At night no rest can be obtained, and the patient's appetite, which, until now, has been excellent, begins to fail.

April 29, no change.

April 30, great weakness in consequence of loss of sleep and appetite. The painfulness and also the inutility of the pains, which are growing shorter, continues. The only change is a slight swelling of the os. The patient is greatly discouraged.

Up to this time the treatment consisted in the application of active measures, calculated to increase the severity of the uterine contractions, and for this purpose two baths were given daily, tepid vaginal douches used three times a day, four litres being used at each douche, with the addition of a little carbolic acid. Also as much exercise as possible, such as walking about the room, etc. All this supplemented by a nutritious diet, wine and brandy. The intensity of the suffering was relieved somewhat with antipyrine, and suppositories containing laudanum.

As no advance was being made, and as the situation seemed a most hopeless one, I attempted a slight dilatation of the os, although it was evident that the cause of the trouble did not lie in this direction. The os was soft and smooth, and normal contractions would have caused speedy dilation.

On the first of May, after five days of labor, the patient had an attack of delirium. She threw herself wildly about on the bed, rolled up her eyes, and called out unintelligibly, as if in the greatest fear. I was at once called, and found the patient somewhat quieter, but otherwise about in the same condition. I now made several incisions in the os, without, it must be confessed, expecting much from them. In the evening of the same day it was seen that the procedure had been ineffectual. Practically, the local

condition showed that the patient was still in the first stage of labor, while her dangerous weakness and exhaustion were most alarming and the altered frequency of the fœtal heart sounds, showed that the situation was a most critical one. Calling in a colligue, we agreed that the immediate extraction of the fœtus was necessary to the mother's life, and, accordingly, perforation, with Levret's shears, and extraction was speedily performed. The pains did not even prove sufficient to expel the after-birth, although energetic massage was performed for about an hour, and finally this had to be removed manually. The fœtus was that of a large child, weighing 3,500 grammes, and of normal development. Post-partum hæmorrhage did not occur, and the patient subsequently recovered after a normal lying-in period.

The peculiarities characteristic to old primaparæ, as observed in this case, included, first, abnormal lack of energy and effectiveness of the pains, which, although they recurred at regular intervals, only dilated the os to the size of about a nickle; second, that in the face of an apparently normal physical condition, a so heroic method of delivery was necessitated.

In this case, no existing physical abnormalities justified the weakness of the labor, and the only etiology which could be advanced was the patient's age. The physical strength does not seem to have anything to do with it. Indeed statistics show that in old prima-paræ of vigorous constitution the labor is apt to be weaker than in constitutionally delicate patients of the same age. The question of etiology is, therefore, a most difficult one to answer, but one which I sum up in the following sentence:

The mechanism of parturition—if I may use this expression—loses its power of exact work with the increased age of the patient. This loss of power is caused principally by inaction, due to long sterility, and increases with the age of the patient.

Regarding the treatment of these cases, no definite rule can be laid down. Everything depending upon the severity of the case. If symptoms of extreme exhaustion or excitability are present, the mother's life is in great danger, and the fœtus should be at once mechanically removed. Until then it should, very naturally, be the aim of the physician to save both lives if possible. It should, however, always be endeavored to save the mother from danger, and any operative procedures which would imperil her life for the sake of the child's, are not to be entertained.

Incisions into the os may, or may not, be effective. More heroic measures have been offered, such as Dührssen's method of cutting deeply into the external orifice until the vaginal wall is reached, in order to render the application of forceps possible. Such procedures, even if undertaken with every precaution, including strict asepsis, cannot be regarded as anything but dangerous, yet the operation has proved successful in experienced hands. Tamponing the cervix and vagina with iodoform gauze is another rational method often valuable in strengthening the pains and dilating the os.

Regarding the operation of Cæsarian section, in my opinion, the risk run by this operation, although it has reached so high a grade of perfection, is too great to warrant it, when by sacrificing the child's life, an extraction per vaginam can be easily effected. Still, the operation is one for every operator to consider in such cases.

Experience is, after all, the best teacher in these cases, and at the same time the hardest teacher, and in this lecture I can only hope to have forewarned you, so that you may not be dismayed when meeting a case of the kind.

CARDIAC HYPERTROPHY AND DILATATION—BRONCHITIS—RETRO-PERITONEAL SARCOMA—ENLARGED GALL BLADDER.

BY FRANCIS DELAFIELD, M. D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

CARDIAC HYPERTROPHY AND DILATATION.

Gentlemen:—You have here a man 22 years of age, a laborer by occupation, who was apparently in good physical health until about one month ago. At that time he was taken sick, complained of a good deal of pain about the right shoulder joint, with frontal headache, cough with expectoration and vomiting, and great physical depression. After suffering with these symptoms for a day or so, he was compelled to take to his bed, and remained there for a couple of weeks. At the end of this period he got up again, the pains in his head disappeared, his strength gradually returned, and he felt in a position to be able to go back to work again. He remained at his work this time for about four days when he suddenly, and without any appreciable cause, began to experience great

shortness of breath and palpitation, and these symptoms persisted up to the time of his coming to this clinic for the first time, which was five days ago.

Physical examination of this man then showed a condition of the heart the same as he at present has. He had then some râles over both lungs, giving us the physical signs of a general bronchitis, and he had a pulse of 140. He was advised to go home, remain perfectly quiet, and was put on the use of iodide of soda. We find him now not looking particularly bad, and he feels well enough to go back to his work, although he still has dyspnœa. The bronchitis has apparently disappeared and there are no physical signs of anything wrong with the lungs at the present time.

When we examine this man's heart we find it considerably hypertrophied and dilated, but without any murmer, and one, though laboring under excitement that is quite marked, still, when he is quiet, acts fairly well. We find a pulse showing no evidence of increased arterial tension.

This is all the clinical knowledge we can obtain in this man's case, and though it is easy enough to give the cause of his illness a month ago, which was due to the prevailing epidemic, it is not now so easy to say why he has a heart that illustrates one of the examples of hypertrophy and dilatation, without valvular lesion, developing suddenly. Why such a pathological condition should develop in this case we do not know, but we do know that this young man, in ordinary physical health, began to complain of an abnormal cardiac sensation, with dyspnœa, and presenting all the physical characteristics of a heart hypertrophied and dilated, in the course of a day or so. Patients who develop in this way this form of cardiac hypertrophy and dilatation have a very extreme and distressing dyspnœa, and in many cases the heart's action cannot be brought under control.

There can be no question as to the propriety of keeping this man absolutely quiet until his heart's action is a little better than it is at present. Though he feels physically better than he has been, he still should not be permitted to go to work for the present. He should still continue the use of the iodide of soda, as he has been apparently improving under its administration, but should he not keep on improving, it would then be a question for us to determine whether he would not do better under the administration of the chloride of barium or aconite. The iodides, chloride of barium, and aconite, are the three drugs I would especially recommend for his use. This condition is not, by any means, a common one, and is an extremely interesting one of its sort.

BRONCHITIS.

The next patient is a boy, 16 years of age, who was brought to us from the country. He was in apparently good health until within the past seven months. During this period, however, he has complained of very little in particular, but his mother notices he has been steadily losing flesh and strength. He has had some cough, and a headache. He has now a temperature of 101° F.

On physical examination of this boy's lungs, I am able to detect the signs of bronchitis of the larger tubes, and he has, at the apex of the left lung, as compared with the right, resonance of a higher pitch and shorter duration, which pathologically denotes thickening of the pleura and consolidation of the lung on that side. Over the lower part of the right lung behind, I find a localized area of subcrepitant râles, without any marked change in the percussion note, which would mean either a localized pleurisy or inflammation of the lung substance at that point.

This is all the history we have of this case and these are all the physical signs that we can obtain, but they are not of sufficient clinical significance to warrant us in giving more than a probable diagnosis. I should be quite unwilling to say positively what is the nature of this boy's trouble, but from the absence of any marked symptoms and from this steady wasting away, I should be inclined to regard it as tubercular in origin. We have not as yet had an opportunity to examine microscopically this boy's sputa to determine the presence or absence of bacilli.

I should be inclined to put this boy on the use of cod liver oil and creosote, if he is able to bear it, and note its effect on his physical condition.

RETRO-PERITONEAL SARCOMA.

The next patient I present to you, is a man 70 years of age, who tells us that he was in his ordinary health up to three months ago, at which time his bowels became constipated, and this constipation has persisted up to the present time without any amelioration in its character. The form of constipation he has is that the bowels moved every two or three days, and then they had to be moved by the use of purgatives. He then passed hard fecal matter and he gives us no history of an inter-current diarrhœa, nor is

there a history of the passage of fecal matter diminished in size.

Besides this symptom of constipation this man complains of, he has been evidently losing flesh and strength, and has lost ten pounds in weight, he tells us, since the commencement of his present illness. His appetite has, however, continued good, and he has had no gastric symptoms until within the past few days, when nausea suddenly presented itself. He has also had, of late, a slight œdema of the feet, but more marked on one side than on the other. His urine has a specific gravity of 1,007, but contains no albumen.

Now, as we look at this man, we can at once notice his loss of flesh and strength. We notice also, as he lies on the table, an unnatural fulness about the centre of the abdomen, and we also observe that there is increased peristalsis, with a marked depression below the ribs laterally. I find on palpation a solid mass at about the middle of the abdomen, which is apparently as large as an orange, and hardly movable with my fingers. At the lower portion of the abdomen, and in the vicinity of the left groin is another but smaller mass which appears to have some movement on palpation. You can notice very distinctly the outlines of the larger mass in the abdomen change with the movement of the diaphragm.

Looking at this large mass in that way, it would seem that it was made up of a number of coils of intestine which are more or less matted together, and it would further seem as if these coils of intestine are more or less in motion all the time, changing their position continually from side to side.

With this history of this man's case, and the pathological condition of his abdomen, at the present time, the question naturally suggests itself to our minds: What is the nature of this tumor? One gentleman calls it a carcinoma of the peritoneum. That diagnosis might be possible, but this tumor is not evidently attached to the anterior wall of the abdomen, nor does it seem to be attached to the omentum, nor to the intestines, and these are the ordinary positions of a neoplasm that originates in the peritoneum. It is not a movable tumor and is attached to the posterior wall of the abdomen. Tubercular infiltration of the glands, another gentleman states this trouble to be. That is not very probable in this case, for the man has no history of tuberculosis. There are such pathological conditions as tubercular infiltration of the glands of the mesentery, but this diagnosis would hardly apply to the case before us. Chronic intestinal obstruction of some kind, is the answer of another gentleman. That would account for the constipation this man complains of, and for the increased peristalsis, but in what way are we to account for the presence of this hard mass? If there is a fecal mass in the colon, that intestine usually is movable. It would be very proper, indeed, to think of incomplete obstruction of the colon to account for a large part of this man's trouble, but, as to the exact nature of that obstruction it would not be so easy to say. We might suppose that a new growth existed in the wall of the colon, and there are curious examples of chronic inflammations that obstruct the colon in one way or another. Some sort of obstruction of the colon unquestionably exists here, but still this is not a case of ordinary obstruction. He gives up the clinical evidence of obstruction of the colon, and he also gives us evidence of this solid tumor which is attached to the posterior abdominal wall.

A gentleman says that this tumor is a retro-peritoneal sarcoma. With this diagnosis I am inclined to agree, and this tumor is evidently of that character. This man has had, at some time, a peritonitis, and this peritonitis has matted together the intestines, offering in this way interference, to a certain extent, to the passage of fecal matter through the intestine.

The way to treat this case is evidently to try and keep this man's bowels as freely active as we can. He has no pain, the tumor is not of a large size, and I see no reason why he should not be able to get along very well for a considerable length of time, providing we can get his bowels to move regularly.

ENLARGED GALL BLADDER.

I will now relate to you the particulars of a case I saw in consultation a few days ago in the hope that it may prove of some practical interest to you. I was called to see in consultation, a young man, who gave me the following history. He was 35 years of age, and of somewhat intemperate habits of life. He sustained, while under the influence of liquor, a traumatism over the region of the liver. This injury did not at first trouble him in any way, but, in the course of a day or so, pain developed over the region of the liver, some fever set in, and the patient felt so very sick that he was compelled to take to his bed. He remained in bed for some time, the pain and fever continuing, and he began to waste gradually

away. After suffering in this way for some weeks, an enlargement was noticed over the liver, and this enlargement persisted up to the time I was called to see him. When I came to the bedside of the patient he was vomiting constantly, appeared to be very much emaciated, and had that peculiar expression suggestive of septic poisoning.

The attending physician thought of the possibility of abscess of the liver in his case, and on aspirating that organ drew out no pus. The most noticeable feature of the man, besides this change in his general condition, was the appearance of the liver. The upper border of that organ was a little higher than normal, while its lower border beginning at the left side, came down symmetrically and regularly into the abdominal cavity as low down as the umbilicus. The liver was not only enlarged downwards, but also forwards, so that the anterior abdominal wall was pushed up, presenting all the characteristic outlines of an enlarged liver.

The physician who was in attendance made a diagnosis of amyloid degeneration of the liver, but this seemed to me to be altogether out of the question. I thought that the man had either a suppurative process going on in the liver, or a rapid neoplasm of that organ, though the appearance of the man was strongly suggestive of suppuration. I was embarrassed from the fact that aspiration had been done and no pus withdrawn. I was furthermore embarrassed from the fact that the patient, when I was called to see him, was so sick that I did not deem it right to aspirate the second time, and obtain positive evidence of the existence of pus in the liver, for I thought that the doctor, in aspirating, had not penetrated the liver substance sufficiently deep. Whether he had one or more abscesses of the liver, or diffuse suppuration of that organ, a pathological condition that sometimes occurs, I was not certain.

This morning I received a note from his physician, stating that the man had died, that his liver had been examined, and no suppuration existed. The tumor was an enlarged gall bladder, and instead of enlarging after the manner of the normal gall bladder, which is pear-shaped in form, it spread out under the under surface of the liver, so as to form a symmetrical and continuous tumor with that organ, and this is what gave, on physical examination, the appearance of an enlarged liver. The gall bladder, on examination, was found distended with pus. This fact never entered into my mind on arriving at the question of diagnosis. There was no cause for this pathological condition, except the blow he received over the region of the liver.

COMMUNICATIONS.

RESECTION OF THE OPTIC NERVE.

BY L. WEBSTER FOX, M. D.

(SECOND PAPER.)

Shortly after my first paper made its appearance on the above subject, I again had the opportunity of putting to a test the efficacy of this operation. The immediate disappearing of all sympathetic symptoms, the freedom from pain, the rapid recovery, the saving of an eyeball, make me give the details of the following interesting case.

Mrs. Kate Guest, age 25, of Palmyra, N. J., at the age of three years, had her *left eye* punctured by a fork. The tine entering at the lower and inner quadrant, close to the corneo-scleral margin in the ciliary bodies. This accident was immediately followed by an attack of sympathic ophthalmia, in which the sympathizing eye—the right—became totally blind, the left passing through the attack none the worse; the vision remaining good until November of 1886, when the right eye became irritated and inflamed causing the left one to become the seat of sympathetic iritis. It is interesting to note that the eye which was originally the seat of injury now became the attacked eye, seventeen years after the primal wound; in other words, the right was now the starting point of the migratory ophthalmia and the fulmination taking place in the apparently healthy one. At this stage the patient came under my care at the Germantown Hospital. The diagnosis was simple, although the left eye did not present any untoward symptoms. The patient complained of a "mist before her eye." An examination revealed iritis, the iris having become attached to the anterior capsule of the lens; having *seclusio pupillae.*

The patient had very little or no pain during the fading away of the vision. It was a case of "slow iritis," where the vision was blurred and the patient did not realize her danger until too late.

I immediately performed an iridectomy on the nasal side of the left eye; first to prevent further progress of the iritis, and second, to give a better pupil for vision.

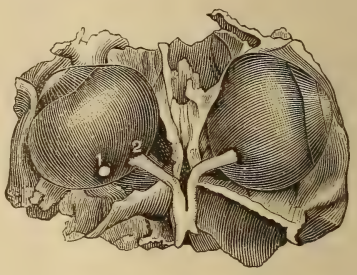
The internal treatment was hydrarg, bichlor. and potassa iodidi, pushed to their fullest limit. The eye rapidly grew better and useful vision was obtained. ($\frac{20}{70}$ J. $\frac{8}{6}$″) glasses did not improve sight, owing to a slight deposit of iritic pigment on the anterior capsule of the lens. The patient was married in 1887, and during her pregnancy, which followed shortly afterwards, she had a mild attack of dimness of sight, but attributed it to her physical condition.

In the latter part of 1889, the third attack came on, which materially lessened her definition of objects for distance. Having removed from the city, shortly after her marriage, she did not seek the professional advice of a medical man during the attacks, but depended solely upon such domestic remedies as hot water, tea leaves, etc., etc.

In February of this year she had a fourth attack, which caused vision to fall very rapidly to $\frac{5}{200}$, which so alarmed the patient that she sought my professional advice immediately. The attacks all seemed to start from the right eye, blind one, which was sensitive to pressure, with at all times some lachrymation, the tears being scalding and coming on in floods, at intervals; these symptoms always being the precursor of hazy vision in the left eye. At this examination I found in the right eye, which was partially atrophied, pain on slight pressure, but not at all angry looking. The left had a diffused Descemitis; iris musty and scarcely any reflex to be obtained through the artificial pupil which I made in 1886. Vision was very defective, fingers could be counted at about five feet against a black back-ground.

In 1886 I suggested the removal of the right eyeball, but owing to the young woman having hopes of a speedy marriage such advice was not entertained. The operation of resection of the optic nerve was suggested and when it was explained that the eyeball could be preserved, while the source of the migratory ophthalmia cut off, her consent to a resection was given and the operation was performed, under ether, March 15th, 1891. Vision began to clear on the second day following, and so continued from day to day until May 6th (last examination), when vision had returned to $\frac{20}{200}$. Very little or no discomfort followed the resection, in fact the patient returned home in ten days. At present the scar visible in the operated eye is nothing more than one would find after an advancement or tenotomy of a muscle.

I have recently been making experiments upon rabbits to decide whether the nerve should be severed immediately at its bulbar attachment or further down the trunk. My experiments prove that it is safer to cut the nerve as close to the eyeball as possible; by so doing one lessens the chances of a reunion. In the rabbit the optic nerve enters the eyeball at a right angle to its basilar end, which lies under the anterior lobe of the brain. As soon as the nerve is severed the ocular muscles turn the eyeball on its equatorial axis, and in consequence the nerve becomes displaced down and in, in some cases one-fourth of an inch.



The above figure represents a post-mortem drawing of an eyeball of a rabbit five weeks after a resection operation. 1, represents the optic nerve entrance turned out from its original position; 2, the optic nerve-end down and in, which was attached to the eyeball by organized tissue. The relative position of optic nerve entrance and nerve-end has been accurately preserved. The illustration is life-size. The fundus oculi was examined with the ophthalmoscope immediately after the resection. The arteries were found empty, while the veins retained sufficient blood to show their outlines very distinctly and so remained until the death of the rabbit five weeks later. In the rabbit the distribution of the blood-vessels is unlike that in the eye-ground of the human subject, while opaque nerve fibres extend beyond the equator in a narrow ribbon-shaped band, exceedingly bright and silvery, across the horizon. The eyeball did not change in appearance, the cornea remaining bright and clear; no change in the color of the iris nor crystalline lens. I am convinced that where the operation for resection of the optic nerve is carefully carried out, we have a better substitute than enucleation, and with proper instruments it becomes a very simple procedure.

I can only repeat what Dr. de Wecker has said, "that the only way to prove conclusively that resection of the optic nerve can take the place of enucleation is that a

large number of resections shall be made and the results noted."

The above case, which I have described carefully and somewhat at length, is one in which I feel sure a resection of the optic nerve is as safe a prophylactic measure as enucleation, and in addition I have saved a particularly morbid woman from the disagreeable necessity of wearing an artificial eye.

1304 Walnut St.

TYPHOID FEVER.[1]

BY DR. RIGG,

ALLEGHENY, PA.

Typhoid fever, gastric fever, typhus abdominalis, enteric fever and infantile remittent fever are a few of the terms used to designate a peculiar continued fever of long duration, usually attended with diarrhœa, and characterized by peculiar intestinal lesions, an eruption of small rose spots, and enlargement of the spleen. In common with other continued fevers, typhoid fever is due to the introduction from without of a specific poison into a system more or less predisposed to the disease.

The nature and origin of the poison, and the modes in which it is propagated, are questions of interest and importance. Two distinct views have been held with regard to the origin of the poison, one that it is specific in its nature, and derived only from some pre-existing case of the disease. The other, while usually produced in a person suffering from fever, it may also be generated anew by the decomposition of sewage and perhaps other forms of animal filth.

It is accepted on all hands that typhoid poison is reproduced in the system during the fever, and that its chief, if not exclnsive outlet is the intestinal discharges.

There is no evidence that it is conveyed by the breath, perspiration or urine, but while it is in the intestinal discharges it is not as virulent when first avoided as after it has been allowed to stand awhile. Warmth, stagnation and seclusion from open air intensify the poison.

There is now very little opposition to the above theory—Murchison, of the older, and Harley, of the more recent writers, excepted. The former supporting the sewage gas origin, anb the latter the effect of derangement of function, he denies the infectious nature of the disease, and holds that a chill or wetting is sufficient to determine congestion and the resulting phenomena of enteric fever. With the above exception, the mind of the profession seems to be almost a unit as to the specific cause of typhoid or enteric fever.

The mode through which the poison may find an entrance to the human body is still a question in the minds of many able investigators. As it stands to-day, we might say the probabilities are in favor of the following in the order in which they are named:

First, Infected water. *Second*, Infected milk. *Third*, Infected ice. *Fourth*, Air being infected with the dried spores through dust. *Fifth*, Digital infection. *Sixth*, Infected meat. With reference to the first, or water source, there seems to be no limit to the evidence that might be collected were one disposed to spend the time and labor to collect it; we will therefore only refer to a few cases in which that seems to be the cause.

Mr. Charles V. Chapin reports on the epidemic fever in Providence, R. I., in its relation to the public water supply. It was found that the fever had prevailed at Natick, three and one-half miles above the pumping station which supplied the reservoir. It was learned that the excrement had been thrown on the river bank. The time between a heavy rain which would wash the excrement into the river and the outbreak was about fifteen to twenty days; deduct from this three days which would be required to get from river to consumers, and we have about twelve to seventeen days as the time of incubation.

This is in accord with the report given by Dr. Taylor in 1885, to the State Medical Society of the Plymouth epidemic, which was clearly traced to a case in the mountains on the bank of a stream that supplied the reservoirs.

The time which this got into the reservoir was, if I remember correctly, March 26th, and the outbreak April 9th to 15th, at which time it was in full force, also, in accord with a report by myself in 1884, to the Westmoreland County Medical Society, of an outbreak at Alice mines, in which one case was brought to a house where the closet was located just above a spring. About the third week there was a heavy rain, causing the vault to overflow, at which time I went to the superintendent and asked that the spring be closed up, when he informed me that it was the best water on the place and could not do it.

After trying to explain to him the reason,

[1] Read before the Allegheny County Medical Society, March 17th, 1891.

and failing, the matter was dropped, and in about seventeen days typhoid fever began to develop, we had in all twenty-four cases, all except one got their water supply from the above spring.

At this time the company ordered the spring closed, and the trouble ceased. Dr. Anderson reports a peculiar teat eruption in the milch-cow, in conneetion with an outbreak of enteric fever among the consumers of the milk, at Dundee. There is also a report from Leeds, showing milk to be the probable source of infection. I have been unable to find any well authenticated cases traceable to ice, but the fact that a low temperature does not destroy the germ, makes it a possible source of infection.

The air may be the source not so much by carrying the germs themselves, as by carrying the particles of dust, or other matter, that may contain the special poison.

It is impossible for a current of air to detach bacteria from moist surfaces, they must first dry. I think it possible to account for many isolated cases, that could not be accounted for in any other way.

As to digital and meat infection, they, in my judgment, are only possible and not likely means of communicating the disease.

As to diagnosis we will say but little, as the disease is too well known to you to justify taking your time, only a few points will then be noticed:

The invasion is usually insidious, more or less headache, muscular weakness, general depression, with pains more or less through the body, slight chills, as a rule not severe, loss of appetite, epistaxis, yellowish white coat on tongue, bowels confined or relaxed, if confined, usually open freely from slight purge, urine high colored and diminished in quantity, pulse and temperature above normal. The patient will have the appearance of more depression than will be accounted for by the temperature or duration of illness, the face is often a very useful guide in making an early diagnosis. One very important thing to do is to exclude any local inflammation as a cause of the pyrexia. The abdomen may be tumid with some tenderness of right iliac fossa, but the abscence of this does not exclude enteric fever. The gradual and continuous rise in temperature together with above symptoms and abscence of local inflammation, will leave us fairly sure of the character of the trouble. Then if we get a free yellowish green stool from slight purge, we may feel sure of our case, the rose spots will soon begin to make their appearance, a short cough is often present, sometimes severe with sibilant râles, If the pulse is much above one hundred per minute, you can look for a severe case,—if below eighty or ninety most likely a mild one.

Relapses are common in enteric fever; this if a true relapse is not simply a return of pyrexia, but a return of all the phenomena of fever. I have seen the third relapse with all the symptoms well marked, with a period of five to ten days between the ending of one and the beginning of the other.

As to the special symptoms and complications hæmorrhage is perhaps the first to attract our attention. This occurs in about eight per cent. of cases, usually after the fourteenth day.

Perforation also may occur, andis a very fatal complication.

Peritonitis without perforation may occur, and in typhoid fever may exist without any very great tenderness, but with a good deal of tympanites.

If great tympanites occur early in the disease, say the first week, it is an unfavorable indication. Diarrhœa is usually present though not often hard to control, and if not excessive not especially dangerous. The urine usually contains albumen in the early stage, and by some is looked on as a diagnostic sign. Ehrlich's urinary test is also regarded as of great diagnostic value. This is the characteristic red coloration of the urine, and is made by adding 25 parts of a solution of sulphanilic acid in dilute hydrochloride acid, 1 to 20 to 1 part of a 5 per cent. solution of sodium nitrite, and the whole mixed with an equal part of urine.

I have had no experience with this test and cannot speak of its usefulness. Pneumonia is very apt to develop in the later stage if the patient is exposed to any draft. It has been my rule for the past eight years to have the bed so placed that the door would open and shut without a draft passing over the bed. The windows should be just as carefully watched. It cost one man his life to teach me that lesson. Pulmonary gangrene, pleurisy, thrombosis and embolism may occur in the course of the fever or at its close. Parotitis going on to suppuration occurred once in my hands; there was no fistulous opening left after recovery.

Phlebitis has several times appeared as a sequela to enteric fever. Arteritis is also reported in which the femoral artery was occluded and amputation was necessary.

Sudden death may occur in typhoid fever from bulbar paralysis, capillary hemorrhage in brain, and from the much used and abused heart failure. There is nothing in the early

state of a typhoid patient to indicate that the fever will assume the abortive form; this, however, will most likely become manifest, by about the eighth or tenth day. The scope of this paper will not admit of the consideration of either the abortive or irregular forms of typhoid fever. In enteric fever the prognosis should be guarded on account of the long time the case will most likely run, and the risk to some of the complications; very high temperature or rapid pulse indicate a severe and possibly a dangerous type.

The treatment should be largely symptomatic. The patient should be placed in a large room, well lighted and well ventilated, any unnecessary articles of furniture should be removed. The body should be sponged off night and morning in tepid water; if the skin is hot and dry a little bicarbonate of sodium should be added to the water; if sweating is profuse a little vinegar. The patient should be handled with care, all traumatism to the abdomen should be dispensed with. Either violent or unnecessary palpation or food that is not in a liquid state. The great tendency of typhoid patients to develop tuberculosis should cause them to be protected from any possible exposure in that line. In the early state a few doses of the mild choride q. s. to empty the bowels and put them in an aseptic condition, will be good treatment; this may be given with naphthalin in three or four grain doses. Naphthalin is said by some to be more of a destroyer of the typhoid bacteria than calomel, but the latter would receive my confidence in the first few days. It lessens the subsequent diarrhœa and leaves the bowels in a better and more healthy condition. The statistics show that cases receiving the mild chloride at the onset of the disease run their course in about two days less time than those not receiving the same.

As to the antipyretic treatment, high temperature in any specific fever is an indication of danger, not the cause of it. Temperature is only a part of a specific fever. Sub-normal temperature is due like elevation of temperature to disorder of the thermotaxic centers. Perhaps the best antipyretic we have is the cold pack or the spray of cool water as practiced by Hiller and others in sun-stroke.

Antipyrine, antifebrin and phenacetine should not be used as antipyretics in typhoid fever. It has been my experience also, that large doses of quinine given throughout the disease had the effect of prolonging the disease, and I have failed to see any good in any way from its administration.

Carbolic acid and tincture of iodine, resorcine, turpentine, the acids, etc., have all been used with more or less success. The important thing in my mind is to keep the stomach in as good condition as possible, the bowels aseptic, patient quiet and well nourished with liquid food, and you will give your patient the best chance to get well. Complications must be treated as they arise.

Society Reports.

ALLEGHENY COUNTY MEDICAL SOCIETY, MEETING MARCH 17TH.

Dr. Rigg read a paper on *Typhoid Fever.*

(See page 655.)

Dr. Kœnig: I am pleased to see the prominence that Dr. Rigg has given to infection through air. I believe that is a source of infection frequently overlooked by city physicians. The infection to which I refer is found only in cities in which there is a system of sewerage. I am perfectly clear in my mind that I have seen a number of cases of typhoid fever the infection of which could be traced to sewer pipes, in which there were no traps, that led directly from the underground sewers in which the intestinal discharges of typhoid fever cases are thrown throughout the year. We can readily understand that the germs will multiply there and that they will rise with the vapors, for if odors can rise from the sewers into sleeping apartments, certainly these minute germs to which I believe we all consider the disease to be due, can also rise, and I think it is the duty of all physicians to inspect the sewage of a house in which cases of fever have occurred, and to prevent any one sleeping in an apartment in which there is no trap to the waste pipe, and I believe, furthermore, that the air saturated with the germs of the disease which have deleterious influence on the course of the disease, and the removal of the patient from such a room would be judicious. I wish also to say a word in favor of the drug that Dr. Rigg has recommended, namely, napthalin. I have used it in a few instances, perhaps not sufficiently often to decide regarding its merits with absolute certainty. I have used it where there was considerable tympanitis, with uniform success. It is an extraordinary germicide, and in repeated doses of two or three grains will disinfect the intestinal canal. It seems to me rational treatment to administer a remedy like napthalin if for no

other reason than to destroy the fermentative germs in the intestinal tract.

Dr. Kearns: This subject is so old and trite that it is perhaps difficult to raise profound interest in it, but perhaps there is no subject that should engage our attention more thoroughly and more carefully than typhoid fever. When I commenced to practice, over thirty years ago, it was the great disease, requiring more attention than was given to the treatment of almost any other disease, but now it has lost that interest, owing partially to the fact that other ailments have grown to occupy a large share of the professional attention. I think Dr. Rigg's paper was a fine resume of practical points in which he dwelt principally on causation, diagnosis and prognosis. Of course it is unnecessary to go into the anatomical and clinical condition, neither is it necessary to dwell on causation. However, I am not prepared to admit that this is due exclusively to outside influences communicated by microbes. That it has no other source of generation I am not prepared to admit and never have been. I agree with some of the old authorities who studied this disease many years ago and saw it in its true type. I never come across a case now such as I came across twenty-five years ago. At that time whole families would be taken down, four and five one after the other. Now it is seldom that more than one in a family is afflicted with the disease at the same time. Then, these cases were invariably characterized by a peculiar tongue, and by symptoms of the locality of the disease, the ulceration of the glands. I admit that in all my experience and careful study of typhoid fever, it is a difficult matter at the present time to diagnose a case of typhoid, especially at the first time I visit it. I never report a case to the board of health until I have made two or three trips. Formerly, typhoid fever was supposed to come on slowly and gradually. The cases we have now come on abruptly, and I always defer my report until I am certain about the fever. I believe it is to a certain extent auto-genetic. I am borne out in this supposition by men who have studied the matter much more than I have. I believe that great mental worry and strain on a system partially prostrated will throw that patient into typhoid fever. I believe, therefore, that is not dependent upon germs. However, I believe that germs will come in and infect, as in the excretions from the sewers through the cess-pools, but I have no doubt that we can have typhoid fever come on auto-genetic. Having started out many years ago with a treatment which was successful, I have never changed it. I never use any of the recent remedies. I think the systematic, scientific treatment of typhoid fever is by preparations of acids. Quinine in small doses is required. The great remedy I have always relied upon is turpentine. Half a drachm every two or three hours. I have no confidence in the treatment that will reduce typhoid fever by reducing the the fever. I would be afraid to use cold douches. Strong stimulants are necessary to keep up the vitality.

Dr. Batten: I agree with the paper and of course I have no criticisms to make, but there are conditions in the treatment of typhoid fever that requires us to move very carefully. These conditions we do not meet in a mild case of fever. I have treated a mild case of typhoid fever in an old lady sixty years of age without any medication and she did excellently and recovered. About fifteen years ago I had a very malignant case of typhoid fever, pregnant about three months, and she ran on very badly until the third week, when miscarriage took place and she lost an immense amount of blood in the miscarriage. There was no decomposition in the fœtus. I had some trouble in getting the placenta delivered, but after it was delivered, and she had lost this blood, the whole type of the fever seemed to have changed, and she made a fine recovery. I do not mean to say that blood-letting in her case would have been the proper thing. Another case that came under my notice. Some of you will recollect that about twenty-five years ago morphia was recommended in cases of delirium to make the patient sleep. This case I saw had been under the care of a physician in Pittsburg, and the patient was delirious, and it had taken three men to hold him. He was taken to Passavant's hospital. It was about the time cold packs were introduced. I put him in a cold pack twenty minutes and afterward gave him a good dose of whisky. It lowered his temperature and changed his condition and he went to sleep and slept for eight or ten hours soundly, and the disease went on without difficulty to a good recovery. I should state that his temperature when he came into the hospital was about 104.

Dr. Lange: I was very much pleased with Dr. Rigg's paper and the society certainly is indebted to the doctor for the brief but comprehensive résumé presented. There was one point which struck me as being a

little incomplete, and which it is profitable to consider a little more in extenso than Dr. Rigg did and this is the occurrence of pneumonia which Dr. Rigg ascribed solely to changes of the temperature of the atmosphere in the sick-room. Now, there are two kinds of pneumonia occurring in typhoid fever, one of which is very fatal, and the other not so. The pneumonia which is not very fatal and which occurs in typhoid fever frequently is croupous pneumonia. I believe with Dr. Rigg that croupous pneumonia occurs frequently in typhoid fever from change of temperature of the atmosphere, and Dr. Rigg has with him, probably, the majority of the profession, in ignoring the pneumococus. The other form of pneumonia which is very fatal in typhoid fever is catarrhal pneumonia. It frequently is the direct result of the dirty mouths of patients and comes when the patient is late in the disease. It has been called for this reason deglutition and inhalation pneumonia and is a preventable complication. On the other hand croupous pneumonia comes about the second week. These catarrhal pneumonias are as a rule preventable, and it is the catarrhal pneumonias which make a large death rate in typhoid. It is difficult to keep the mouth clean. In a recent report from Germany where they use the cold bath so extensively, there were reported one hundred cases of typhoid fever without one death, no medicines being used, nothing but the cold bath and scrupulous cleanliness of the mouth. When I had typhoid fever, five or six years ago, I was treated to a cold bath with very bad result. It was followed by an aggravation of an already existing mild bronchitis and coryza. We must conclude that the Germans are a different race; they are more rugged and hearty than the people who live here. They are more rugged than the people we have to treat. You can see that in the emigrants; you can see their full habits and faces, their cheeks red with blood, and their lips scarlet.

Dr. Green: I wish to compliment Dr. Rigg on the paper. His treatment is almost parallel to that which I followed for a number of years with regards to the disinfecting of the intestinal canal. I wish to speak more especially about a remark offered by Kearns to the effect that the typhoid fever of the present day is not the typhoid fever of twenty years ago. I cannot conceive why it is not and I think we would be mistaken were we to conclude that the doctor is right. I think the typhoid fever of the present day is as severe as the disease ever was. Of course we have had epidemics of a mild type of typhoid, but that is no argument in favor of a different type of typhoid to what we formerly had. It is well proven that the typhoid germ exists in typhoid fever, and I think it is acknowledged at the present time and I have no doubt that the germ existed previous to the discovery a considerable length of time, and I think that what causes the apparent change in type of typhoid fever is the treatment at the present time. The sanitation and medication, I think is due to them.

Dr. Thomas: I expected to hear more said with regard to the prophylaxis of typhoid fever. I am in the habit of telling patients who have typhoid fever the fact that they have taken into their mouths something to cause the disease. I think the greatest thing we can do for typhoid fever is its prevention, and no one can use a greater influence in bringing about that condition than the medical profession. On the South Side we get it once in a while, and we get it under certain conditions just as sure as the sun rises. The circumstances are these: If the river remains low for a number of weeks and the water gets below the combs of the dams, we have stagnant water. In the pool from which we draw our water we have the sewerage of the entire South Side above the lock. What do these sewers carry? Fecal matter; they are constructed to carry fecal matter. In addition to that, we have all the sewage and refuse of Soho, from Minersville, from Hazelwood, and in addition to that, we get the sewage from Homestead, Braddock, and so on. As sure as we get these conditions, we have typhoid, and the epidemic generally comes on within three or four days. We will have to-day three or four patients with symptoms of fever, to-morrow four or five and the next day six or seven, it gets all over the town and that condition lasts until we get a big freshet to sweep out the pool. So far as the medical profession of the South Side is concerned, we have resolved, and have had the resolutions published in the prints of Pittsburg, that the entire cause of the epidemic is bad water. It is said that in Berlin at the present time typhoid is rare, simply because they have a good water supply. Before, it was very common. They tell me that in Johnstown, where the water is gotten from the mountains free from contamination by these germs, they do not know what a case of typhoid fever is, only through cases that come there from other

places. We might talk a good deal about typhoid fever; the proper thing is to stop the fever.

Dr. Stevenson: The paper was a very comprehensive, full and truthful statement of the knowledge of typhoid fever to-day. The discussion has covered a number of points embodied in the paper, but there are others, enough left untouched to keep this society talking a long time. I was a little surprised at the statement of Dr. Kearns that certain conditions of depression and nerve disturbances could produce typhoid fever. I presume the doctor would admit that a case of fever originating in that way would transmit the disease to other people. Now, how could nervous disturbance and mental strain originate a specific disease and transmit it to another person? I am unable to understand how to expect this. I think this much is true; that the conditions have a depressing effect and a patient in that way is more exposed to the germs and is more apt to contract the disease. Another of the speakers seemed to be at a little loss to explain the recovery that followed an exhaustive hæmorrhage occurring in an abortion in a pregnant woman with typhoid fever. I think the secret is that he had a patient who had a complication. He had a patient who was pregnant, undergoing typhoid fever. The patient lost the pregnancy, the hæmorrhage did not happen to kill her and she was in a better condition to get well. It has occurred to me that it is a little curious that both in the paper and in the discussion that has followed, there has not been a single word dropped as to typhoid fever in children. The profession are certainly well aware that typhoid occurs with great frequency in children. It is estimated by the best authorities that one in six of the total number of cases is in children. The diagnosis in children is probably the most important part of the matter. As a rule, typhoid fever in children is mild, but it has been very often mistaken for other diseases.

I do not know that the paper specifically mentions the condition of the tongue in typhoid, but I think this one of the most characteristic symptoms. A moist, heavily coated tongue, with a red area and a red tip. I am not aware that the condition comes in any other disease. In regard to the treatment of typhoid: Typhoid is a self-limiting disease; it has a certain course to run, and the only danger is some complication or some mismanagement that changes the type and character of the disease. Dr. Kearns thinks there is a great difference between the cases of typhoid which he saw earlier, and which we now see. I think the main difference is in the way they are managed. I saw a case in consultation not very long ago in which I found the patient unconscious, with the abdomen like a barrel, tongue dry, lips all cracked and covered with sores. I asked the doctor what he had been doing. Well, he had put the patient on half grain doses of calomel every four hours. "How long did you keep that up?" Five days. "Why did you stop?" The patient had had diarrhœa. "What did you do then?" The patient was put on sugar of lead and opium, grain and a half of sugar of lead, and half a grain of opium. This for four days. The patient's mouth, tongue and lips were all very dry. "What did you do then?" Put him on turpentine and have him on turpentine now. He is no better. I said, "Doctor, put this man on an ounce of whisky every hour and three pints of milk a day, and give him nothing else, he will get well." And he did. It looked to me as if that physician had been treating a disease he had produced. He gives calomel which causes diarrhœa; then he gives sugar of lead and opium to stop the complaint. Then he turns around to remove the effects of the sugar of lead aud opium by the use of turpentine. I think there is very little danger in typhoid fever when the temperature is under 104. If the temperature does not exceed 104, it is well enough to let it alone. If it gets above that it is over the danger line. I think about all there is to it in typhoid is to see that the temperature does not get beyond this danger line, and to see that we do not lose our patient through some complication.

NEW YORK SOCIETIES.

NEW YORK ACADEMY OF MEDICINE.

Meeting of April 16, 1891.

The President, Dr. Alfred Loomis, in the Chair.

Is Embryotomy of the Living Fœtus Justifiable?—A paper by Dr. Egbert H. Grandin opened the discussion on this question. He thought that, in view of the great progress in abdominal surgery during the past decade, the time had come when the question of the justifiability of fœticide should receive earnest consideration. Ten years ago, when the mortality from the Cæsarean section was forty per cent on an average, embryotomy had been a beneficent necessity. To-day,

however, when sepsis had been practically banished as an after-complication of abdominal surgery, when we knew how to effectively suture the uterine wound so as to guard against gaping and internal hæmorrhage, when the fear of opening the peritoneal cavity had been proved groundless, the time was at hand when the physician had the right to question if, under all conditions, he was called upon to mutilate the living fœtus. On moral grounds the speaker would not discuss the question. Theologians could not decide the point for obstetricians. If the latter could once prove that the risk to the woman from the Cæsarean section was no greater than from embryotomy, their duty as well as their pleasure would be to save two lives instead of, as in the past, destroying the lesser. If our data concerning the Cæsarean section continued to improve over those of the present time, the choice of operation would lie purely with the physician and not at all with the laity, who would always claim precedence for embryotomy over the Cæsarean section. One important factor lacking toward the desired end was more thorough education of the student in pelvimetry. The Cæsarean section should be *elected*, even as an ovariotomy or a hysterectomy was. The operation should never be left as a *dernier ressort*. A difficult embryotomy subjected the woman to as great risks as the *elective* Cæsarern section. Shock was the element to be feared chiefly after both operations, and the speaker had witnessed greater shock after embryotomy than after the Cæsarean section. We must learn, further, not to rest our conclusions on the statistics at present at our disposal. These were very fallible, seeing that they included many instances where the section was not elected. The record of individual operators from the elective Cæsarean section gave a fair estimate of the results obtainable in the future. Thus, certain German operators had a mortality as low as six per cent. Hertsch had reported seven cases with no deaths; Cameron, ten cases with one death. At the New York Maternity Hospital the record for the past two years was four elective sections, all successful as regarded both the mothers and the children, while during the same period there had been four craniotomies with one death. The speaker trusted, therefore, that surgeons to maternity hospitals would with one accord cease doing embryotomy, and perform the Cæsarean section under the relative as well as the absolute indication, deliberately electing it. His belief was thus, in the near future, the maternal mortality could be lowered at least five per cent, while fully ninety-five per cent of the children could be saved. These results would pave the way for the election of the Cæsarean section in private practice.

Dr. H. J. Garrigues thought that the statistics by no means warranted the assumption that the Cæsarean section, even with the improvements of modern surgical technique, was an operation of less danger than craniotomy. The chances of saving the mother were five times as great in craniotomy. The only measure that seemed to him to offer a pretty good chance of success to the mother was the induction of premature labor, and where the case was seen in time, he thought that this was the proper thing to do.

Dr. R. A. Murray was in favor of elective Cæsarean section. When the deformity of the pelvis was such that no other operation could be done, the question of previous unsuccessful results was not to be considered. In the hands of the ordinary operator he thought that the Cæsarean section would probably yield as good results as embryotomy.

Dr. W. T. Lusk did not admit that the dangers of craniotomy were of so grave a character as those of the Cæsarean section, and he thought that it was an error to allow the idea of an equality in the dangers of the two operations to be promulgated. In large hospitals it was true that the results of the section had been good, but in the same hospitals there had been no deaths from craniotomy. While he disliked extremely to do a craniotomy, and would always avoid it if he could, his experience with the Cæsarean section had been such that he would do the former operation in preference, other things being equal.

Dr. C. Jewett, of Brooklyn, would perform embryotomy on the living fœtus: 1. As an alternative of other means of delivery by the natural passages in certain rare emergencies for the rapid termination of the labor in the interests of the mother. 2. As an alternative of the Cæsarean section: (*a*) When the mother was exhausted or her condition otherwise unfavorable for the abdominal operation; (*b*) when the conditions were not favorable for the child; (*c*) in disproportion between the pelvis and the fœtal head, but with a conjugate of from two inches and three-quarters to three inches or *more*, provided the mother so elected, after a full knowledge of the facts.

The life-saving capacity of the modern Cæsarean section for the mothers could not

be estimated at more than from seventy-five to eighty per cent. The average maternal mortality in embryotomy was about ten per cent. and was less in proportion as the pelvis was more roomy.

The choice of operation must take into account the skill and experience of the operator in abdominal surgery. The Cæsarean section was an operation for the expert, embryotomy for the general practitioner inexperienced in abdominal section. It was not true that the two operations were equally within the skill of every practitioner. Every physician became more or less familiar with the operating field of the obstetrician. Few had any practical knowledge of the surgery of the abdomen. The rights of the child must be ignored, but the rights of the mother must be paramount.

SECTION IN GENERAL SURGERY.

Meeting of April 13, 1891.

Dr. William T. Bull in the Chair.

Lumbar Nephrotomy.—Dr. Robert Abbe presented a patient who, five years before, had begun to suffer from renal colic and hæmorrhage. This condition had become continuous during the last two years. Six weeks since, the patient had come to him for advice, and was at that time suffering from hæmaturia. Examination with the cystoscope distinctly demonstrated that the bloody urine came from the right ureter. Nephrotomy was accordingly performed. The kidney was found perfectly normal on palpation. It was stripped free of the surrounding fat. Fifteen punctures were made. At only one of them was the operator able to feel anything apparently abnormal. It seemed as if the needle struck something gritty. An incision was made, enabling the speaker to pass his finger well into the pelvis of the kidney, but there no stone was found. The finger had come in contact with the gritty point before mentioned, which might have corresponded in feeling to a papilla of one of the pyramids. The wound was accordingly closed. There was no trouble resulting from the operation and no escape of urine from the wound. The interest seemed to lie in the fact that since the operation the patient had remained free from pain and there had been, so far, no return of the hæmaturia.

Dr. R. F. Weir said that there was a class of lesions sometimes found in the kidney which, though trifling enough in itself, caused a tendency to bleeding from the organ. It was at present too soon to form any conclusion as to whether a cure had been effected in the present case or whether the diseased condition was of the class he referred to.

The Treatment of Hernia by means of the Hank Truss.—Dr. S. E. Milliken in a paper on this subject, referred to the danger of producing excoriation or at times severe sloughing with the ordinary trusses of the shops. If this condition was brought about it made the treatment of hernia in young and delicate children exceedingly tedious and occasionally impossible. The hank truss, of which the speaker thought too little was known, was constructed from a loop of zephyr of the best quality containing from twenty-five to thirty strands. It was made of sufficient length to encircle the pelvis between the anterior superior spinous process and the trochanter major, with enough left to make a perineal strap. On one end a double tape was attached, corresponding to the affected side, and passed through the loop coming from the opposite side. Considerable care should be given to the adjustment of the loop. The method might be described as follows: With the index finger of the left hand passed through the loop and allowed to rest perpendicularly on the median line of the abdomen, ordinary tension should be made. The tape was now passed through the loop and the additional force necessary to bring the point of the crossing to the inguinal region would usually give sufficient support to retain the hernia. The free or tape end was then carried under the thigh of the affected side and tied to the band going around the pelvis. Where a double hernia existed, the second hank should be applied irrespective of the first. The truss might be worn a week or ten days without changing if the proper use of absorbants was made, and the best of these was sudiodide of bismuth. This powder might be renewed daily after giving a sponge bath. During the first few weeks no change of the apparatus should be attempted by the mother or nurse, for only after considerable technique had been acquired could protrusion be prevented, especially when dealing with a restless child. When the truss was worn as he explained, and was not changed more than once a week, and no protrusion was allowed to take place, at the end of two months it might, as a rule, and in the absence of contra-indications, be discontinued. Only one case of recurrence had come under the speaker's notice after cure by this truss, and in this the hernia had only recurred on one side, whereas a double hernia had formerly existed. He

was able to report some two hundred and sixty-eight cases treated by this method, and to present to the meeting a large number of patients in various stages of the process of treatment. He had concluded that among the advantages of the hank tress were: 1. Easiness of manufacture, no delay being encountered in the beginning of treatment. 2: Absence of spring pressure or severe elastic pressure and a lessened liability to produce excoriation or sloughing. 3. The pressure could be regulated without removing the truss. 4. Less weakening of the tendinous and muscular structures, which so frequently followed the use of ordinary trusses. 5. There was no danger of adenitis from pressure on the inguinal glands.

Dr. Abbe said he had at one time made an unsuccessful attempt to make use of this truss and had abandoned it, as it had seemed to cause pain. From what he had seen of its application in the cases presented, however, he thought it was a most seductive form of treatment, and he should certainly take it up again.

Dr. W. B. De Garmo desires to protest against a return to what appeared to him a relic of the past. For the practitioner located where he could not procure a suitable truss at once, this was a very convenient bandage for temporary use, but he should not consider himself justified in leaving it on as a permanent appliance. At this day, when we had many good trusses that could be worn by the most delicate infant, if properly applied, he felt that we had no excuse for using something that was neither cleanly nor efficient. It was true that many children were readily cured, even by the crudest appliance, but it was equally true that many others were allowed to go by the curable age by the use of a "makeshift" of this kind. A well-known institution where these bandages had been applied had recently furnished his clinic at the Post-graduate Medical School with abundant evidence of the unreliability of this so-called hank truss. According to the histories given, these children were all worse when they came to the clinic than when the bandage had been applied, and in most instances the yarn was in a filthy condition. Cleanliness, simplicity, and durability seemed to him the essential points in selecting trusses for infants. All these features were combined in the rubber and celluloid covered truss, with which the country was well supplied. These, fitted by the lead tape diagram method, appeared to leave little to be desired in the way of appliances of this kind. Nine-tenths of all hernias occurring in children under five years of age could be cured by a suitable truss; this implied the proper fitting of the truss and the keeping of the patient under observation until he was cured. If mechanical treatment failed, he should consider an operation justifiable.

The Curative Effect of Operations per se.—This was the title of a paper read by Dr. J. M. White, of Philadelphia, in which he considered an elaborately complied aggregation of the reported experiences of others, supplemented by his own, as to the palpable or possible evidence, immediate or remote, of the relief of symptoms, or the subsidence of concrete indications of pathological conditions, resulting from surgical interference, stopping short, however, of radical procedures. There was no lack of both startling and amusing data upon which to establish a theory that operations *per se* were sometimes productive of curative results, even where investigation could determine no macroscopic or microscopic physiological disturbance to account for the existing symptoms. The acceptance of this evidence, of course, landed the investigator upon that *terra incognita* in which such ambiguous phrases as hysterical manifestations, psychic influences, and reflex phenomena were the only terms left for the description of an unknown quantity.

Dr. Abbe was of the opinion that certain growths might be the result of mental influences producing changes in the circulation, disturbance to the physiological equilibrium, and ultimately a pathological product. When an exploratory operation was of benefit in these cases, it was because a change was brought about in the tissues by the manipulation of the lymphatics, the nerve filaments, and the vascular structure of the tumor itself. He thought, however, that the acceptance of the theory might lead to mischievous results from reckless operating for experimental purposes. Such cases should only be undertaken by those able to accurately weigh the chances of benefits to the patients. He did not believe that many instances of cure would be recorded.

Dr. H. J. Boldt did not believe that any malignant disease of the abdomen would disappear upon simply opening the region. In cases in which this result had been affirmed he considered the diagnosis had been incorrect.

Dr. Weir pointed out the fact that the tumors which disappeared after surgical in-

terference were generally situated in the abdominal cavity. He had never seen a tumor in the leg disappear under like conditions. In the abdominal cavity it must be borne in mind that there was an immense sympathetic nervous system. The interference with such a region might set up such disturbance as would bring about changes in the circulation, and thus influence the nutrition of any existing neoplasm. He was, however, very skeptical as to the curative effect of operations *per se*.

The further opinions expressed were in the same vein. It was conceded that psychic influences might be potent, but that they could not at present be demonstrated. For the most part the benefits which were derived from operations *per se* were due to retrograde metamorphoses in existing growths or to the irritative disturbances of existing conditions of malnutrition.

SECTION IN GENERAL MEDICINE.

Meeting of April 21, 1891.

Dr. R. C. M. Page in the Chair.

American Childhood from a Medical Standpoint.—Dr. Henry Ling Taylor read a paper with this title. The human organism, he said, was pre-eminent in its marvelous adaptability to the most varied surroundings and conditions of life. It had complex mechanisms for the reception, conveyance, storage, modification, and discharge of the showers of impressions constantly received through the sense organs and through the nerve endings in the skin, membranes, and tissues. We recognized that different individuals and races reacted somewhat differently; they had inherited or acquired special characteristics of mind and body, probably largely due to habits evoked by special surroundings and ingrained by frequent repetitions, either in themselves or in their ancestors. Which way did life in New York push the children? We knew that the city children with whom the physician was brought in contact got too little light and air, did not take enough of the right kind of exercise, were often overfed or underfed, lived in houses that were kept too hot, were often urged too much in their studies and especially in their emotions, and frequently, with shortened childhood, became little men and women before emerging from pinafores and knickerbockers, The children had, as a rule, the following characteristics: Weak ankles, strong legs, weak waists, shallow and inelastic chests, and weak shoulders and arms. The pale countenance and cold extremities gave evidence of a faulty circulation. The feelings and will might be intense or flabby, but in either case betrayed the lack of discipline. There was precocity in knowledge of people and social relations, and there was the darkest ignorance with regard to most natural objects and processes.

If the parents were in easy circumstances, the children were, as a rule, produced with difficulty from an overtaxed and undernourished stock, not from the superabundant vitality of robust natures. The mother rarely had vitality left to nurse her infant, and it was brought up on some substitute, which at best was only a makeshift. Whatever modern life had done for women, it did not seem to have prepared them for the intelligent care of their offspring. If our city life was so artificial that we required gymnasia, field sports, and outings to keep a descent physical equilibrium, we still needed to give some attention to vascular gymnastics, and the culture and development of the unstriped fibers which played so fundamental a part in our vital economy, by placing some reliance on the adjustive and resisting powers, and by a systematic and judicious exposure of the skin to cold water, air, and the vicissitudes of weather. The city child, instead of soil with its diversified coverings, had hard and mostly level floors or pavement; instead of grateful greenish, bluish, or brownish tints, the patchwork surface of our houses and streets; and instead of restful silence or simple, harmonious sounds, the irritating jar of complicated noises. Young city children of the primary-school classes had the most extraordinarily distorted ideas about the commonest natural objects, and much of this mass of misinformation remained in adult life. On the other hand, they were abnormally precocious in their knowledge of men and social relations and in general "knowingness." That the modern methods of school education produced many bad results was seen in the nervous condition of many children, in their headaches and ocular and other troubles. Nature was a good schoolmistress, and her lessons were the fundamental ones, no matter how much we might supplement them at school or university. The infant was learning his lesson when he was kicking out his legs, waving his arms, or bumping his head, the child playing tag or batting ball, or the youth working with his carpenter tools, or riding a bicycle, just as truly, perhaps more truly, than the university student burning midnight oil over Greek and calculus. Nature was never systematic in the school sense, and, however much we might system-

atize, we must at the same time cultivate our powers and round our individuality by keeping in close touch with so much of nature as lay within our horizon in a restful, informal way. Family life was perhaps the most important factor of all in the child's development, physical as well as mental and normal. The system of flat housekeeping prevented our women from being good house-wives, and the high-pressure work for the mighty dollar rendered the men anything but agreeable fathers; so that children really saw but little of what ought to go to make up a home for their training. Much of what had been said applied to certain classes in certain localities, and it might be thought that the physique of the children that were now growing up under our eyes was not, on the whole, satisfactory, and that it was a difficult matter to bring up wholesome, hearty children in New York. If this was so, it was well to recognize the fact.

The Chairman thought that the children in the cities were subjected to dangers which were overlooked. One was that their bowels were constantly neglected, and another was that they were allowed to go about with wet or damp shoes.

Dr. F. A. Castle argued that if attention to the bowels was neglected by children, it was the result of the present bad arrangement as to school-hours. Social usages had gradually pushed the hours for meals—that is to say, for dinner—later and later in the day, but the nine o'clock school-hour never changed, and children were often rushed off to school without adequate food or any other attention to natural requirements. He also deprecated the whole system adopted in the primary schools. All that the children did was to shout some nonsense in concert. The schools were simply bedlams; the system adopted not only served no purpose, but actually did damage to those who had to undergo it.

Dr. C. E. Quinby thought that to meet the requirements of the age, and especially of city life, it was necessary to turn out specialized men and women; and, this being admitted, there was a tremendous advantage in city life, which would put a child at twelve years of age where a person of twenty would not be in the country.

Fel Bovis Inspissatum as a Therapeutic Agent.—Dr. W. H. Porter read a paper on this subject. He made a most emphatic appeal to his hearers on behalf of what he had decided to be the great therapeutic utility of fel bovis inspissatum in all diseases which had for their source, or were under the influence of, pathological conditions of the digestive economy. He stated that the conclusions which he was urging had been arrived at after ten years of persistent use and careful observation of the drug. Adequate confirmation of the speaker's view of the matter was given by other observers, special emphasis being laid on the advantages accruing from administration of the ox-gall throughout cases of typhoid fever.

The Value of Auscultatory Percussion as a Method of Diagnosis.—This was the title of a paper by Dr. F. W. Jackson.

Dr. J. West Roosevelt complimented the author on the integrity of the work done and the conclusions drawn so far. He thought that the paper ought to show the value of auscultatory percussion and serve to make the method more popular. He was, however, sorry to hear that throughout the series of observations the nipple had been used as a landmark. Its position upon the chest was not constant, relatively, in any given number of subjects, and it was an utterly unreliable factor in measurements. The mid-clavicular line was very much to be preferred.

SECTION IN OBSTETRICS AND GYNÆCOLOGY.

Meeting of April 23, 1891.

Dr. Egbert H. Grandin in the Chair.

Birth of a Viable Child at Six Months and a Half.—Dr. H. Collyer reported a case of this nature. The woman was thirty-three years of age, had been married eleven years, and had had four children at term and one miscarriage. She had been under the speaker's care for chronic pelvic peritonitis, which fact had given him opportunities for observation in the case that he might not otherwise have had. On July 5, 1890, she menstruated as usual. On August 6th there was a scanty flow for three days. During the third week in August changes were noticed in the uterus characteristic of the earlier weeks of pregnancy. The woman stated that conception must have occurred on July 13th, denying its possibility before that date. On January 4, 1891, while she was working a sewing-machine, there was sudden and profuse hæmorrhage. All attempts to prevent labor were futile, and on February 3d she was delivered of a small male child weighing two pounds and two ounces. The child cried at once, and, wrapping it up warmly, the speaker waited for some five minutes till pulsation in the cord had ceased before separating the child from its mother. The placenta gave some

trouble, and there was found attached to it an independent lobule. The bones of the child's skull were soft and overlapping. The testes had not descended, and the finger nails were only just showing. The infant was wrapped in wool and put into a basket, which was placed near a fire kept continually burning. At first the child was fed with milk and water from a spoon every two hours, and subsequently from the breast. It had since continued to thrive in every respect. The date at which the child was born and the general condition of its development would indicate the period of gestation as six months and a half.

The Association of Rectal and Pelvic Disease in Women.—Dr. R. A. Murray read a paper with this title. When the anatomical connection between the genital organs and the rectum was considered, it was not strange, he said, that many diseased conditions of the one set of organs reacted on the other, and, further, that they sometimes had a causative relation. The vascular supply of the uterus, ovaries, and tubes was indirectly connected with the lower third of the rectum. The veins on the left side emptying into the left renal vein, the varicose condition of these veins was oftentimes the cause of symptoms of ovarian hyperæmia, and even of acute oophoritis. Constipation was not absolutely a disease confined to the rectum, but in a large proportion of cases it was a symptom which, if not the cause, was surely a concomitant of uterine trouble. The inflammatory diseases of the uterus and its annexa, tube, ovary, and ligaments, were, of all uterine diseases, by far the most frequently seen by the specialist. The first symptom present in almost every case was pain in the left side, over the ovary; next, flatulence and constipation. When the anatomical relations of the tissues in these parts were remembered, the cause of this condition of things was easily accounted for. In chronic displacements of the uterus—retroversion of retroflexion—the long-continued pressure of habitual constipation obstructed the circulation to such an extent that hæmorrhoids resulted, and the parametritis generally fixed the uterus on the rectum so that the use of cathartics only excited the inflammatory symptoms and made the patients afraid to take the remedies. In such cases the uterine symptoms were most prominent, and no relief was experienced until the communication between the portal and genital circulations was made freer. This was to be done first by correcting the displacement, secondly by relieving the constipation. For the constipation, enemata were to be preferred. Another result of chronic constipation was pouching of the lower third of the rectum. This condition was found frequently in virgins and gave rise to pain in the back, discomfort in standing, and the sensation of dragging and fullness, with a feeling that the parts would fall, due to the distention and varicosity of the vaginal and uterine veins caused by the formation of proctocele, which pressed the vagina forward. The author had seen fissures in the vaginal entrance which were painful and intractable, and which could only be cured by relieving the constipated habit and correcting the proctocele. In chronic retroversion, where the uterus was pressing on the rectum, and in chronic fixation of the uterus in any position, from pelvic peritonitis, the author had found that with constipation, and even without it, many patients complained of a discharge of glairy mucus from the bowels, with a sensation of burning during and after the act of defecation. This mucus was often stringy and in links. Following this, there might be a bloody discharge, particularly at the menstrual period.

On the relief of this catarrhal proctitis by aseptic injections of boric acid or mild astringents, the complaints of pelvic pain were often very materially lessened, although the uterine disease was not cured. Hæmorrhoids and painful fissures of the anus were frequently associated with uterine disease, either inflammatory in nature or due to the pressure of tumors. Where hæmorrhoids were due to uterine pressure, the reposition of the displaced organ was called for. Where this could not be done, much might be accomplished for the patient by keeping the bowels regular and relieving the pelvic circulation by rest in bed. The vaginal douche was indicated. The author had found benefit from the reduction of the hæmorrhoids after each action of the bowels, by pressure, while the patient was in the recumbent posture. It was noticed that most of the symptoms that patients complained of when suffering from prolapsus uteri were the same as those presented in a case of hæmorrhoids, the exception being the pressure of the tumor forward by the pile, the hæmorrhage, and the intense pain on defecation. This suggested that the trouble was really the same congestion of the pelvic veins. Fissures of the rectum often caused dyspareunia, which might be mistaken for vaginismus, and relief of the cause was quickly followed by disappearance of

the symptoms. Any and all of these conditions might be exaggerated, going on to abscesses in the recto-vaginal septum if the cause persisted, and finally producing a general breaking down of the health. In this paper the author's endeavor was merely to outline this subject, as there was so little said by authorities in regard to this particular question. If its consideration directed more attention to closely contiguous and related organs, he believed that many errors in diagnosis would be avoided and much more benefit result to patients.

Dr. H. J. Boldt said there was no doubt that this subject had been much neglected, and that the presence of rectal disease was too often overlooked by gynæcologists. In four-fifths of his uterine cases the patients were examined *per rectum* and obscure symptoms very often cleared up thereby.

The opinion expressed by Dr. Boldt was that of the speakers who followed him, and the author of the paper was thanked for bringing before the Section points full of practical suggestiveness.—*N. Y. Med. Jour.*

Special Correspondence.

London Letter.

THE LONDON UNIVERSITY SCHEME.—DEGREE FOR LONDON STUDENTS AT LAST. THE KOCH CRAZE.—DR. SYER BRISTOWE'S VERDICT.—MR. STEAD AND THE CURE FOR CANCER. THE EDINBURGH PROFESSOR'S TIE.

After years of wearisome delay and discussion, a scheme has been drawn up whereby the London students may have a chance of getting a degree upon reasonable terms. The proposed alterations have raised a storm of opposition throughout the country. The provincial schools offer the most determined resistance at the very outset to the constitution of the new Senate, and not without some show of "sweet reason," for the provinces are allotted four only out of forty-two seats. The Dean of the Birmingham medical faculty points out the "calm assumption of the metropolitan teachers that, at their mere desire, a great imperial institution like the University of London is to be made a narrow parochial undertaking." Then the present graduates are fearful of the lowering of the value of the degree they have so hardly won. However, the matter may be finally settled, medical students are likely to reap the benefit. The London degree has been so fenced in with high standards and other conditions so as to be practically prohibitic to the greater number of students. As a result, those who want a degree on reasonable terms are forced away to the provinces. Thus the policy of the London school for many years past has driven a regular exodus of students to Edinburgh, Durham, Glasgow and other University towns. Of late there has been a growing tendency to recognize the fact that very high standard examinations are a snare and a delusion, calculated to foster cunning rather than brains. It certainly looks rather like beginning at the wrong end of the stick to send a man out into the world so crammed with details that he has had no time to inquire into the principles of his art.

The Koch craze is about over. After waiting a sufficient time to get reliable results various meetings have been held in different parts of the country to consider the matter, and the verdict has been everywhere alike unfavorable to the remedy. Perhaps the most calm and philosophical summing up of the whole affair from beginning to end has been made by Syer Bristowe. He remarks that "collective results go to show that the use of Koch's fluid tends to cause more or less intense and widespread inflammation round the tuberculous deposits; that this inflammation in no degree tends (as Koch assumed to be the case in order to explain the supposed curative action of his remedy) to envelop and imprison the living bacilli in caseous cocoons, and so to prevent them doing further mischief; but that, as happens in the case of lupus, the inflammation in some cases becomes, from its very severity, a source of serious danger. "There can be no doubt that tuberculin is a very potent poison. The present writer has given it up to doses of a decigramme in a case of *lupus erythematosus* of seventeen years standing, in which the scalp was extensively affected. At first considerable improvement was effected, but at the end of three months things are very much as they were at starting. This result gives a fair echo of the general report, which tells of nothing but vexation and disappointment. And thus we come to the end of one of the most extraordinary chapters in the history of modern medicine. If we were to seek a parallel in outside affairs we could find nothing more nearly resembling it than the tale of the South Sea bubble, when society of all sorts and conditions lost its head over the fabled

treasures of the islands of the Southern Seas.

In the now famous journal, the *Review of Reviews*, Mr. Stead has taken up the cudgels for Count Mattei, the "Italian nobleman," who advertises all over the world cures for cancer. Unfortunately, the medical journals, with one exception, think it beneath their dignity to attempt to interfere in the matter, in spite of the immense harm that must result to the public at large. With his usual energy Mr. Stead has started a test ward of five beds at a small Hospital in London. He has a small committee of supervision, consisting of Sir Morel Mackenzie, Mr. Lawson Tait, and a Dr. Potter, sub-editor of a nursing journal. With regard to these proceedings the *Medical Press and Circular* has a slashing article, calling Mr. Stead's attention to the commercial aspect of the question, and to the fact that Mattei's advertisements appear largely in his own paper. It also remarks that a layman is about as likely to throw fresh light on the therapeutics of cancer as an ordinary man would be to add to our knowledge of the differential calculus. The Count professes to work his cures by means of differently colored electricities. Recent examination by a distinguished London analyst has shown his "green fluid" to be absolutely negative in all its properties, and to correspond to no known substance in nature except water. If that be the case, this old Italian cynic beats the record by making a huge fortune out of the springs of his native country. There is something extremely ludicrous in the idea of retailing water all over the world in small phials at a high price. Some of the details of the Hospital, where the experiments are to take place, are suggestive. The matron is a firm believer in Mattei's powers and is said frequently to have proved the reliability of the "green fluid" in arresting hæmorrhages, indeed, for that purpose she uses nothing else. Of course, average medical men will wonder why on earth the matron of a Hospital should go about stopping hæmorrhages, nor will they be silenced by the assurance that the lady in question is the widow of a Bank of England director. Nurses are made, they will reflect, not born. Then we are told that the Hospital is looked after by two medical men, father and son, one of whom for a long time past has been in the habit of dispensing the Mattei remedies in the out-patient department. All this is taking place in good old conservative England. An editor who has cheerfully faced imprisonment in the cause of social purity, and whose pronounced religious views are of the strongest, is persuaded that an Italian layman has discovered the secret of curing a disease that admittedly baffles the efforts of legitimate surgery. Mr. Stead has the courage of his opinions when he backs this Italian advertiser to do what many thousands of his own countrymen, earnest men, trained in the study of disease, have hitherto failed in doing. Verily, *nemo omnibus horis sapit*—a proverb that is especially true of editors in quest of sensational copy.

The following is told of the Professor of Surgery at Edinburgh. In the course of a clinical demonstration he turned to a student who had just commenced his studies, with the question: "Now, Sir, can you tell me what is wrong with my dressing?" The ingenious youth turned red, and preserved a discreet silence. Mr. Chiene, however, was not to be put off, and repeated the question. After a long pause the youth stammered out in a fit of desperation: "Well, Sir, if you insist on my telling you, I should say your tie is not quite straight." As might be surmised this unexpected answer quite "brought down the house."

D. W.

Selected Formulæ.

OINTMENT FOR ALOPECIA.

The following combination is recommended in the treatment of alopecia (*Poitou méd.*, Jan. 1, 1891):

℞

Gallic acid	3 grammes.
Essence of lavender	1 gramme.
Vaseline	30 grammes.
Castor oil	20 grammes.

M. This ointment is used by means of friction upon the scalp.

CREASOTE IN THE VOMITING OF PREGNANCY.

Kaatzer, in the *Berliner Klin Wochenschrift*, gives the following formula for creasote in the treatment of obstinate vomiting of pregnancy:

℞

Creasoti pur.,	2.0 grammes.
Spirit-vini rect.,	30.0 grammes.
Tinct. gentianæ,	
Extr. coffeæ, aa.	10.0 grammes.
Aquæ dest.,	100.0 grammes.

M. et Sig. To be well shaken. Dose: One tablespoonful two or three times a day in a little milk.

The effect of this mixture will be found most gratifying.

FORMULA FOR SULPHATE OF QUININE.

The *Revue Internationale de Bibliographie Médicale*, April 25, 1891, gives the following formula in which, it is claimed, the bitter taste of the quinine is entirely absent:

℞
Sulphate of quinine..... 0.5 gramme.
Dilute. sulphuric acid..... 0.5 gramme.
Essence of menthol..... ..... 5 drops.
Saturated solution of sugar 10.0 grammes.
Distilled water .....90.00 grammes.
M.

VOMITING OF PREGNANCY.

The following is highly recommended by an exchange:

℞
Menthol.....grs. xv.
Alcoholis.....ʒ v.
Aq. dest.....ʒ iv. M.
Sig.—ʒss every hour.

ERGOTINE IN GONORRHŒA.

Roicki, in the *Viadomosci Lekarski*, speaks highly of the efficacy of ergotine in the treatment of gonorrhœa. He gives the drug both internally as a pill, and locally as an injection, using for the latter the following formula:

℞
Ergotine ..... 0.30 gramme.
Dist. water.....300.00 grammes.
M. et Sig. For injection.

The injections should be made several times a day. The drug is well tolerated, and a speedy cure usually obtained.—*Journal de Méd. de Paris*, April 26, 1891.

TREATMENT OF SENILE PRURITUS.

Resnier, in the *l'Union Medicale*, recommends the following treatment for senile pruritus:

℞
Acid carbolici ..... 4.0 grammes.
Acet. aromat.,.....200.0 grammes.

Two tablespoonfuls of this solution should be added to a quart of water and the body washed with it every night before retiring. After drying, the body should be dusted with either of the following powders:

I.

℞
Bismuth. salicyl.,.....20.0 grammes.
Amyli pulv.,.....90.00 grammes.
M.

II.

℞
Acid salicyli pulv.,..... 20.0 grammes.
Amyli pulv.,.....180.0 grammes.
M.

EPILATORY PASTE.

Unna, in the *Allgemeine Med. Central-Zeitung*, gives the following for an epilatory:

℞
Baryii sulphur,.....10.0 grammes.
Amyli pulv.,..... .....
Tinc. oxyd., aa..... 5.0 grammes.
M.

Enough water should be mixed with this powder to make a stiff paste, which should be spread over the parts where a removal of hair is desired. The paste dries in about ten minutes, and then may be lifted off. The skin beneath will be found to be smooth and hairless. The paste will not irritate unless used again the next day over the same spot.

MOUTH-WASH.

The *Apotheker-Zeitung*, May 15, gives the following formula for an anitseptic mouth-wash:

℞
Salol ..... 2 grammes.
Menthol..... ..... 3 grammes.
Ol. menth. piper..... ..... 3 grammes.
Spirit Anisi..... 9 grammes.
Alcoholi .....200 grammes.
M.

The mixture may be colored with a little cochenille. It is very popular in Germany.

FISSURES OF THE TONGUE.

The *Allgemeine Med. Central-Zeitung* recommends the following formula for fissures of the tongue:

℞
Acidi carbol.,..... 2.5 grammes.
Tinct. jodii,
Glycerini, aa.....12.5 grammes.
M. et Sig. To be painted over the fissures.

FOR CHAPPED, ROUGH, OR FISSURED HANDS.

The following formula is claimed by the *Wiener Med. Wochenschrift* to be the most efficaceous application in cases of chapped, roughened or fissured hands:

℞
Tinct. benzoes,
Glycerin, aa..... 5.0 grammes.
Lanolin.....30.0 grammes.
M. et fiat unguentum.

Wash the hands in tepid water, then without having dried them, but merely shaking the water off, apply the salve and rub it in morning and evening. Gloves should be worn during the night.

TREATMENT OF OBSTINATE CORYZA.

℞
Salicylate of soda,
Syrup of orange peel, aa.....15.0 grammes.
Peppermint water.....90.0 grammes.
M. et Sig. One dessertspoonful every three or four hours.
—*Journal de Méd. de Paris*, April 26, 1891.

PRESCRIPTIONS FOR FLATULENCE.

Journal de Médecine de Paris gives the following prescriptions for the relief of flatulence:

℞
Napthol.....1 dram.
Carbonate of magnesium.....1 dram.
Powdered charcoal.....1 dram.
Essence of peppermint.....2 drops.

This is to be divided into 15 powders, and 1 taken at the beginning of each meal.

When the flatulence is accompanied by constipation the following may be used:

℞
Magnesium.....1 dram.
Flowers of sulphur.....1 dram.

To be made into 15 powders, 1 of which is to be taken at each meal.

When diarrhœa accompanies the flatulence:

℞
Bicarbinate of sodium.....30 grains.
Prepared chalk.....15 grains.
Powdered nux vomica..... 3 grains.

May be made into 10 powders, 1 of which is given with each meal.

In still other cases, where neuralgia of the stomach or true gastralgia accompanies the tympanites:

℞
Hydrochlorate of cocaine.....4 grains.
Quinine sulphate.....6 drams.
Cinnamon water.....8 ounces.

A teaspoonful every two or three hours.

EARACHE DROPS.

℞
Camphor chloral.....*m* v.
Glycerin.....*m* xxxiij.
Almond oil.....*m* xxx.

M. Three drops of this mixture on absorbent cotton to be placed in the ear twice a day.

—*Chemist and Druggist.*

LINIMENT FOR GOUT.

The *Lyon Médicale* states that the following liniment is useful in the treatment of gout:

℞
Collodion
Sulphuric acid } of each.....1 drachm.
Salicylic acid
Hydrochlorate of morphine.....15 grains.

This is to be painted over the part affected every few hours.

SEAT WORMS.

℞
Tincturæ rhei.....30 drops.
Magnesia carbonat..... 3 grams.
Tincturæ zingiberis..... 1 drop.
Aquæ q. s. add..... 4 ounces.

M. Sig. Warm and use as injection three times daily.

—*The Doctor.*

OINTMENT FOR PHTHISIS.

L'Union Médicale states that the following ointment is useful in the treatment of pulmonary phthisis:

℞
Creasote.....2½ drams.
Lanolin
Olive oil } of each.....1½ ounces.
Lard

This ointment is to be applied with friction each night to the thorax, and the absorption of the creasote from the skin will be of value to the patient.

PRESCRIPTION FOR WHOOPING-COUGH.

Von Genser is said to use the following prescription in the treatment of whooping-cough:

℞
Carbolic acid.....1½ grains.
Rectified spirit.....2 drops.
Tincture of iodine.....5 drops.
Tincture of belladonna.....10 drops.
Peppermint water.....2 ounces.
Simple syrup.....1 drachm.

To a child of two years a teaspoonful of this mixture may be given every two hours.
—*Medical News.*

CORDIAL FOR INFANTILE DIARRHÆA.

℞
Syr. Rhei Aromat.
Syr. Brom. Comp. Peacock
Listerine (Lambert).....aa ℥ j.

M. Sig. One teaspoonful as needed.

WARTS.

℞
Acid salicylic.....gr. xv
Alcohol.....*m* xvj
Ether.....℥j
Collodion.....℥ij

M. Sig. Apply daily to the warts.

SOLUTION FOR THE REMOVAL OF FRECKLES.

℞
Chloride of ammonium.....1 drachm.
Hydrochloric acid.....1 drachm.
Glycerin.....1 ounce.
Fresh milk.....2 ounces.

Dissolve, and apply night and morning to the part of the skin which is affected.

COPPER IN CHLOROSIS.

Lúton has recommended the following formula, from the use of which Dr. Liegeois has obtained excellent effects in chlorosis:

℞
Neutral acetate of copper.....gr. 1–6.
Crystallized phosphate of sodium..gr. 5–6.
Liquorice powder.....
Glycerin.....aa q. s.

M. ft. tal. pil. No. 12.
Sig. One pill immediately before morning and evening meal.

—*St. Louis Medical and Surgical Journal.*

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

HABITUAL CONSTIPATION.

Habitual constipation is one of the commonest and, very frequently, one of the most rebellious affections with which the practioner is called upon to cope. Recently a number of foreign journals have devoted considerable space to the discussion of this subject. Notable among the contributions are Nothnagel's, in the *Wiener Med. Presse*, and an editorial treatise in the *Revue Médicale*, of Louvain, in which we have collected much important information.

Defecation depends upon the regular contraction of the colon, and especially of the rectum. In the small intestine the fecal matter moves very rapidly (according to Bauhin the entire length of the small intestine is traversed in six or eight hours) while in the large intestine the fecal mass moves much more slowly. Intestinal peristalsis is largely influenced by the nervous system, and only in part depends upon a direct excitation of the muscular walls and the contained nervous mechanism. Innervation of the small and large intestines does not necessarily occur synchronously or similarly—the one is almost entirely independent of the other.

Intestinal contractions, which give rise to the expulsion of feces, occur normally periodically, one defecation occurring every twenty-four hours. This, however, depends largely upon the individual. Some having two or three movements daily, others but one movement in two or three days. Cases are occasionally met with where defecations occur only once in eight or twelve days, and others have been recorded in which defecation occurred from six to ten times in a year! These anamolies are, however, morbid, not physiological, and cases of this kind constitute the affection termed habitual constipation.

The causes of habitual constipation are varied. It may be the result of intestinal innervation, or of atrophy of the muscular

coat of the colon—a condition found by Nothnagel in *post mortem* examinations. The usual cause of habitual constipation is, however, enforced retention of feces, due to a persistent disregard of the call of nature, which is particularly the case in women. Such a state of affairs may be instituted during a long journey by stage or rail, where a false modesty on the part of the sufferer prevents his obtaining relief, or it may occur from willful disregard of the natural recurrent hour for defecation. Again, habitual constipation may be caused by indigestion, the result of a change of diet. An acute attack of intestinal catarrh, not infrequently leaves the patient with this trouble. Nothnagel does not attach the importance to atony of the abdominal muscles, as a factor in habitual constipation, as do other writers. Sedentary habits frequently lead to the trouble, while in some individuals it is hereditary.

The consequences of this condition are also varied, and are not necessarily identical in any two cases. In a certain number of instances hæmorrhoids, with all their well-known inconveniences, are the result. In a majority there is a loss of appetite, the digestive functions of the stomach being for the time depressed, as are also the same functions of the intestines; or it may be that the ptomaines formed in the stagnant intestinal contents, have, by means of their toxic actions, directly affected the digestive powers. Finally, it is by no means rare to find troubles of the central nervous system resulting from this disorder. This may be due either to a reflex action exercised upon the vaso-motor mechanism, or to a veritable poisoning by ptomaines. In the latter the troubles take the form of hypochondria, inaptitude for work, dizziness and vertigo; even cases of temporary insanity have been recorded.

A recent opinion, which has found extensive support among English physicians, has been advanced, claiming that habitual constipation in certain cases causes chlorosis. How far this may be true we are not in a position to say. It is, however, an incontestable fact that many cases of chlorosis have been cured by purgatives alone.

In the treatment of habitual constipation we must largely disregard the symptoms produced, and direct our attention to the treatment of the main point at issue: the trouble with intestinal peristalsis.

In this respect intestinal massage, and especially massage of the colon and rectum is the least used but the most valuable remedy. This procedure not only strengthens the muscular coats of the intestines, but also mechanically hastens the movement of the fecal masses within the intestines. In a similar manner faradization of the abdomen will be found valuable; more rarely a galvanic current is used, one electrode being inserted into the rectum. In the same line of treatment regular exercise and home gymnastics are to be recommended.

It is well, at the outset of the treatment to send the patients to some watering place, where there are mineral springs, and to keep them there during the course of treatment if practicable. If the patient cannot leave home, or as he in this country is not surrounded by mineral springs, as he would be in Germany, any of the many bitter mineral waters, which are mildly purgative, may be given regularly with advantage. Rectal enemata are also very valuable, as well as rectal injections of glycerine, or glycerine suppositories. As a rule, it is best to avoid the use of purgatives, but in a large number of cases this is impossible.

Purgatives may be divided under two heads: laxative purgatives and drastic purgatives. The former merely accelerate the peristaltic movement without irritation, the latter cause a greater or less amount of irritation of the intestinal mucous membrane.

In the first group may be included acid fruits, manna, tamarind, castor oil, calomel, etc., also saline purges. The latter, however, should not be used habitually. Among the drastic purges valuable in the treatment of habitual constipation are principally aloes, rhubarb and podophyllin. The three may be advantageously combined as in the following formula:

℞ Podophyllini.....gramme 0.30
Extr. alœs
Extr. rhei.....aa grammes 3.00
Extr. tarax.....q. s. ad. pil. no. xl .

Sig. One, two or three pills to be taken at night.

Colocquinth is also a very energetic drastic purge, but it is not well to employ it longer than for eight consecutive days. Jalap in large doses is equally useful, but should be avoided as it frequently causes nausea and vomiting. French writers recommend most highly cascara sagadra. The *Revue Médicale* giving the following formula:

℞ Extr. fluid, cascaræ sagad.
Syrup. cort. aurant.....aa, grammes 20.00

M. et. Sig. One or two teaspoonsful every two or threé hours.

In cases complicated with bleeding hæmorrhoids, compound liquorice powder will be found useful. When all other purges fail, senna leaves or croton oil will prove effectual.

If purgatives are used for a long period, it is advisable not to use the same drug, but to change occasionally. Thus Nothnagel begins with the administration of aloes, and follows this by several weeks' treatment with purgative mineral waters; after this compound liquorice powder is given, and finally simple syrup.

Regarding enemata, the continued use of rectal injections of either water, a decoction of chamomile with a little flaxseed, or soap and water, or, finally, of pure glycerine, are frequently productive of excellent results.

Hünerfauth, in his work on the subject of habitual constipation, recognizes only three curative methods: electricity, massage and hydrotherapy.

For the electrical treatment he prefers the faradic current, if, however, the affection is accompanied by pain, the continuous current should be substituted. For the application of electricity the patient should assume the dorsal position with the lower limbs flexed. The current is then applied over the abdomen and rectum, or else within the rectum and over the abdomen, finally, over the sacrum and in the rectum.

Regarding massage, this treatment consists principally of frictions, pinching pressure, kneeding and striking, coupled with careful exercises, such as walking, riding, hunting, shooting and especially mountain climbing.

The hydrotherapy of habitual constipation consists, according to Hünerfauth, in douches over the abdomen, with friction, cold shower baths, and, finally, the application of a wet-pack at night over the abdomen.

In summarizing the various treatments of value in this affection, we must not omit the "cannon-ball treatment," which is, however, fortunately less heroic than its name might lead one to suppose, and consists in a kind of vigorous massage, the cannon-ball being rolled about over the abdomen, and occasionally even raised a few inches up and brought down with considerable force. These novel séances should last from five to ten minutes, and be repeated daily.

Finally, Nothnagel bases a further treatment on the hypothesis that a weakness of the abdominal muscles is one cause of habitual constipation. Dr. Ewer, for example, prescribes a system of gymnastics tending to strengthen these muscles, as an efficient remedy for the trouble. Dr. Enlenberg recommends Sweedish movements, or gymnastics for the same purpose.

In massage of the abdomen, the patient should lie upon his back with the abdominal muscles relaxed and masseur, both in kneeding and rubbing, use considerable force and pressure, following, however, always the course of the bowels, especially of the colon.

CORRESPONDENCE.

THE TREATMENT OF LOCOMOTOR ATAXIA WITH TUBERCULIN.

ED. MEDICAL AND SURGICAL REPORTER.—

The treatment of Locomotor Ataxia has hitherto been so unsatisfactory, both to patient and physician, that anything tending to throw light upon it is welcomed. This, then, is my ground for begging a few moments consideration. I do not write to

herald a new discovery, for I know not that it is new, nor that it is a discovery at all, but to stimulate further experimentation, and to obtain an interchange of experiences. I will briefly give my experience:

On the twelfth day of last March, Henry W., aged thirty-six years, a carpenter, a man of good habits and of good family history, consulted me for "rheumatism," which he stated had troubled him for over four years, and for the past year he had not been free from pain though "doctoring all the time."

Upon examination I found him suffering from well marked Locomotor Ataxia. Though he could walk after a fashion there was marked inability to co-ordinate, sluggishness of pupils, girdle-like sensations, darting pain in the limbs and complete absence of the knee-jerk. I told him there was nothing to do for him in the medical line, but that as I was using Koch's Lymph in the Hospital I would be pleased to try it in his case, as an experiment. Fully understanding that nothing was promised, he readily gave his consent, and the lymph was injected the same day. Reaction followed and the injection was repeated in two days. His pains at first increased, then rapidly diminished, under repeated injections, until at the end of three weeks, they had entirely gone. His co-ordination was much improved and his strength greatly increased. He has had as yet no return of pain, he can work at his trade, walks well, can run and is correspondingly happy.

Meanwhile another case, Ernst F., was under treatment. His sickness was of six years duration. He was entirely unable to walk unless supported, and his pain at night in the abdomen was so severe as to prevent his resting, obliging him to set up a great part of the time. The loss of co-ordinating power was very marked. Soon after receiving injections he became comfortable, could sleep all night, and his strength was markedly increased. He is now practically free of pain and can walk for twenty-five minutes without assistance. He has received no other treatment in the Hospital. At present I have three other cases in Trinity Hospital in which treatment has just begun. Reaction follows regularly. I have no theory to offer in regard to these cases. Can any one suggest one? Trusting to hear from any interested, I am, respectfully, W. H. Neilson, M. D., Milwaukee, Wis.

It is better to work for nothing than to be idle.

Book Reviews.

SURGICAL BACTERIOLOGY. By N. Senn, M. D., Ph. D., Professor of the Principles of Surgery and Surgical Pathology, Rush Medical College, Chicago, Illinois. Second Edition. Thoroughly Revised and Illustrated. Octavo, pp. 271. Philadelphia. Lea Bros. & Co., 1891.

The subject of Surgical Bacteriology is one of such universal interest to medical men of the present day, that any book which presents the status of the subject as it exists to date, based not largely upon mere personal prejudices, but upon the broader basis of incorporating, in compact form, the general outcome of scientific work, cannot fail to be popular with physicians.

The value of Dr. Senn's work and its appreciation by the profession, is shown by the appearance of a second edition within a short space of time.

This noted surgeon and investigator has given to the profession, in this volume, a résumé of the work of standard authorities on the various subjects which are therein discussed. When occasion demands, he does not hesitate to state his own convictions regarding disputed points; and, as the views, so expressed, are the result of careful clinical observation as well as independent original research, they add materially to the value of the treatise.

In the present edition, the arrangement of the work into chapters, not only renders it more useful as a text-book for ready reference, but also permitted the author to better classify the subject-matter.

As the former edition of this work has been fully reviewed in these columns, we will not occupy needless space by a repetition of the merits of the book, suffice it to say that the volume will prove a needed and valuable addition to any physician's library.

SAUNDER'S QUESTION COMPENDS: ESSENTIALS OF SURGERY. By Edward Martin, A. M., M. D. Fourth Edition. Illustrated, Revised and Enlarged, with an Appendix of Prescriptions, etc. Philadelphia. W. B. Saunders, 1891.

This is one of the best compends upon surgery that has been placed before the profession for a long time. Dr. Martin's large experience with medical students, as lecturer and instructor, has enabled him to appreciate their needs, and to amply supply their wants in his "Essentials of Surgery."

In fact, the book, in its present form, will prove not only a valuable aid to the student in systematizing his knowledge, but it also

will be found to be a handy work for easy reference to the busy practitioner.

In this edition the author has added an exceedingly useful appendix, which contains several hundred prescriptions applicable to the treatment of the numerous surgical affections, and, in addition, a list of drugs and materials used in antiseptic surgery, together with very full directions for the preparation of the various dressings, solutions, etc., for antiseptic procedures.

TRANSACTIONS OF THE NEW YORK STATE MEDICAL ASSOCIATION. Seventh Annual Session, held at New York City, New York, 1890.

This volume of more than 600 pages, contains a very full account of the transactions of the association at the meeting held during October of last year. A series of very interesting papers are included in the report; among which may be mentioned:—'Some Personal Observations Upon the Claims of Hypnotism, and Its Employment in Certain Diseased Conditions," by H. Ernest Shmid, M. D., of Westchester Co., N. Y.; "Intercranial Lesions," a discussion by Drs. W. W. Kern, Chas. K. Wills, and John B. Roberts, of Philadelphia; Jas. J. Putnam, of Massachusets; Chas. Phelps, Fred. S. Dennis, Jos. D. Bryant, Thos. R. Manley and John A. Wyeth, of New York County; "A New Method of Surgical Treatment of Certain Forms of Retro-Displacement of the Uterus, with Adhesions," by A. Palmer Dudley, M. D., of New York County; and "The Physician as a Witness," by M. Cavana, M. D., of Madison County, N. Y.

Many other entertaining papers and discussions are contained in the volume, all of which are a credit to the scientific and literary activity of the association.

INTERNATIONAL CLINICS. A quarterly collection of Clinical Lectures on Medicine, Surgery, Gynæcology, Pædiatrics, Neurology, Dermatology, Laryncology, Ophthalmology and Othology. By professors and lecturers in the leading Medical Colleges of the United States, Great Britian and Canada. Edited by JOHN M. KEATING, M. D., and J. P. CROZER GRIFFITH, M. D., of Philadelphia, and J. MITCHELL BRUCE, M. D., F. R. C. P., and DAVID W. FINLAY, M. D., F. R. C. P., of London. Illustrated. J. B. Lippincott Co., Philadelphia, 1891.

In placing "International Clinics" upon the market, the Lippincott Co., have devised a new and valuable scheme for supplying to the profession medical literature both of the latest and best. This "Journal," if so it may be styled, is to be issued quarterly, and is to consist entirely of clinical lectures which have been delivered by the leading clinicians in the United States, Great Britian and Canada. These lectures, reported by competent medical stenographers, are carefully revised by the lecturers themselves before being placed in the hands of the editors. The object of the work is to place in the busy practitioner's hands a journal which shall contain "the very cream of practical medicine and the most recent phases of clinical instruction," as they are given to students and the working physicians in our schools by prominent teachers throughout the English-speaking world.

The initial number for April contains 34 complete clinical lectures upon subjects pertaining to the various departments of medicine, of which the journal takes cognizance. Each lecture is in the form in which it was delivered to the class, and deals with the etiology, symptoms, diagnosis, treatment and prognosis of the subject in hand. Treatment is particularly elaborated in every article, so that all the latest and best methods are presented to the reader at a glance.

In the department of Medicine proper, with which the present issue opens, among other articles are lectures upon "Acromegaly," by Ross, of Manchester, Eng.; upon "Polyæmia or Plethora," by Porter, of New York; on "Angina Ludovici in Its Relation to Diptheria," from Finlayson, of Glasgow; "Sore Throat," by Sir Christopher Heath, of London; "Pneumonia," by Loomis, of New York, and upon "Uræmic Convulsions," by Shattuck, of Boston.

The department of Surgery contains lectures upon "Modern Methods in Surgical Operations," by Keen, of Phila.; "Ulcers," by Cheever, of Boston; "Schirrus of the Breast," by the late Dr. Parkes, of Chicago; "Cholelithiasis," by Robson, of London; and "Abdominal Nephrectomy for Pyolenephrosis," by Nancrede, of Ann Arbor.

In Obstetrics and Gynæcology are the teachings of Mann, of Buffalo, upon "The Early Diagnosis of Pregnancy;" of Cameron, of Montreal, upon "Elevation of the Temperature During the Puerperal State;" of H. T. Byford, of Chicago, upon "Urethritis;" and of Goodell, of Philadelphia, upon "Cancer of the Vagina."

Pædiatrics contains "Tonsellar Diphtheria," by Forcheimnier, of Cincinnati; "Different Types of Paralysis in Young Children," by Gray, of New York; and "Chorea," by Sir Dyce Duckworth, of London.

In the Neurological department, H. C.

Wood, of Philadelphia, contributes a clinic upon "The Remote Effects of Traumatisms as seen by the Neurologist;" Sachs, of New York, one upon "Functional Nervous Troubles and Neurasthenia;" Mills, of Philadelphia, upon "Myotonia and Athetoid Spasm;" Ferrier, of London, upon "Alcoholic Paralysis;" and Weir Mitchell, of Philadelphia, upon "The Treatment of Obstinate Sciatic Pain by Splint-Rest and Cold."

J. Solis Cohen, of Philadelphia, contributes to Laryngology a clinic upon "Stricture of the Larynx."

In Dermatology appear lectures of Fox, of New York, upon "Psoriasis;" of Ohmaim Dumesnik, of St. Louis, upon "Infantile Eczema;" and of Hyde, of Chicago, upon "Xarthema Lichen Planu, etc."

Ophthalmology and Othology are respectively considered by Chisolm, of Baltimore, and Buck, of New York, in lectures upon "Astigmatism an Often Unrecognized Cause of Headache," and "Stubborn Inflammations of the External Auditory Canal."

Of necessity, in the limits of a book notice such as this, it is impossible to give even a short synopsis of the foregoing lectures, and, indeed, where all are equally good the task would be a difficult one. The profession is, however, to be heartily congratulated upon the fact that within the covers of "International Clinics" the results of the work of the ablest teachers of medicine appear so condensed and arranged as to be most easily available and useful.

The journal contains 350 pages, whose typographical make up is excellent. Numerous wood-cuts and photographic reproductions assist greatly in elucidating the text. In these lectures are to be found just what the practitioner wants in the way of the latest theories as to causation of disease, with the newest methods of therapeusis as taught by the ablest clinicians of the day.

CREOLIN IN ALOPECIA.

PERISCOPE.

THERAPEUTICS.

COPAIBA AS AN EXPECTORANT.

Recently balsam of copaiba has been found to be an excellent expectorant in cases of chronic bronchitis. The dose, as advised by the *Allgemeine Med. Central-Zeitung*, April 4, 1891, is 7 grammes daily, to be administered with 30 grammes of malt extract.

PIPERAZIN.

W. Epstein and C. Sprague publish a preliminary report of their investigations with piperazin, in the *Wiener Med. Presse*, April 19, 1891. The drug, which is a new one, has the property of dissolving large quantities of uric acid at the body temperature, and also—what is of greater value—even when a very large excess of uric acid existed, only the neutral and easily soluble uric acid salt would be found. One part of uric-piperazin is soluble in fifty parts of water at 17° C. When it is considered that the solubility of uric-lithion is only 1 to 368 at 19° C., it will be seen that piperazin is seven times more soluble. Piperazin is neither irritating or toxic and is therefore of great value in cases where a dissolution of uric acid is to be accomplished. Experience has shown that the result is well tolerated. The drug is administered hypodermically.

GIBBES-SHURLY METHOD OF HYPODERMIC MEDICATION AND CHLORINE INHALATION FOR PHTHISIS PULMONALIS.

HYPODERMIC INJECTIONS.

As chemicals may cause considerable pain to some people when injected under the skin, the site chosen may be previously treated by the application, for two or three minutes, of a wad of flannel which has been saturated with a mixture of ether and chloroform (equal parts), or, ether (two parts), chloroform (two parts), and menthol (one part), or better still, one of these mixtures may be sprayed upon the part. With many people, however, the pain is only momentary, and they will not require such preliminary treatment. The injection may be made at any time of day and without reference to temperature of the body. The evening will be found generally acceptable to the patient. Although the fluids may be injected at almost any convenient region of the body,

the gluteal region will be found preferable on account of the loose cellular and adipose tissue of the part, and because there is less danger of abscess or sloughing of the skin. The chemicals used should be *pure*, or troublesome abscesses will be likely to occur.

THE HYPODERMIC SYRINGE.

Any hypodermic syringe can be used. Care should be taken to keep the syringe clean. It should be washed with hot water and then with alcohol, or a five per cent. solution of carbolic acid, directly after its use. Drawing a little kerosene oil in occasionally will prevent the packing from getting too dry.

IODINE.

To commence with, the dose of the iodine solution should be about (1-12) one-twelfth of a grain, gradually increasing daily until one-half (1-2) or perhaps one grain is reached, when it may be gradually diminished or substituted at once for the gold and sodium solution. The temperature is likely to go higher for at least the first week, and as the chemical becomes diffused its effects may be shown in increased mucus secretion from the bronchial tubes, sensation of dryness of the throat, redness of the eyes, and coryza, characteristic erythema of the skin, diminution of urine or of diarrhœa, and loss of appetite. During this period there is generally loss of weight. In susceptible patients these symptoms may supervene after two or three injections only, in which case the gold solution should be used. In a few instances, after thorough diffusion, the characteristic reaction of iodine with starch may be obtained in the urine, and even in the perspiration.

CHLORIDE OF GOLD AND SODIUM.

The chloride of gold and sodium solution causes less pain than the iodine, in fact, in the majority of instances no pain save the sting of the hypodermic needle. The dosage, like that of the iodine, should be gradually increased, beginning with about (1-30) or (1-20) grain and increasing up to (1-5) or (1-3) grain. The more immediate effects noticeable from the larger doses are vertigo, nausea, sensation of constriction at lumbar region, and headache, and lowering of pulse tension. With many persons the continued use of this solution will cause profuse perspiration, which, however, is soon stopped or checked by lowering the dose or stopping the use of the chemical. When hectic fever is not broken up by these injections, hypodermic injection of bisulphate of quinine from three to six grains, alternately with the iodine solution, may be given with great benefit.

CHLORINE.

Chlorine may be administered either by directly diffusing the gas in the atmosphere of a small room, or spraying chlorine water through a face-shield inhaler. In either case it must be freely mixed with chloride of sodium. The gas may be evolved from chlorinated lime, by the addition of dilute hydrochloric acid, using from one-half to three drachms of the lime for a sitting, in a room about 8x9 feet and 9 to 10 feet height of ceiling.

Previous to this, however, it will be necessary to diffuse through the atmosphere a spray of a saturated solution of chloride of sodium, which spray should be kept up during the sitting. The patient may be allowed to remain in the room from ten to thirty minutes, according to the effects observed. While so placed the patient should be instructed to breathe through the nose, keeping the mouth closed, and to refrain from talking. If coughing supervene to any great extent the sitting should terminate. One, two or three inhalations may be given daily.

The chlorine water should be carefully made according to the U. S. P. It may be administered as a spray, mixed with a saturated solution of chloride of sodium, in the proportion of one-third to one-half. From one-half to two ounces of the mixture may be used at a sitting, once, twice or three times a day. In some cases after a time a general soreness of the throat may be complained of, when this happens the treatment should be suspended for awhile. Chlorine, by either of these methods, should not be administered where there is danger of hemoptysis.

HYPEROSMIC ACID FOR SUBORBITAL NEURALGIA.

Luciani, in the *Allg. Med. Central-Zeitung*, April 22, 1891, reports a case of suborbital neuralgia, in which hyperosmic acid was used with great success. The patient was a woman who suffered intensely from neuralgia of the right eyelid, and right cheek. All the usual anti-neuralgics had been resorted to without the least relief being obtained. Hypodermic injections of a one per cent. solution of hyperosmic acid gave prompt and lasting relief. The solution was given in syringeful doses, and repeated as required.

EXPULSION OF GALLSTONES.

The treatment of gallstones by large doses of olive oil is a subject that has received almost universal acknowledgement of late, and has been used so extensively that many other means, useful in accomplishing the same results—viz.: the expulsion of the gallstones—have been temporarily overlooked.

Foremost among these are the methods advanced by Prof. Harley, of London. He advises the administration of belladonna, and placing the patient in a hot bath. During the crisis inhalations of the following anæsthetic mixture may be given:

℞ Alcohol,..... 4 grammes.
Chloroform,..... 8 "
Sulphuric Ether,.....12 "
M.

Further, it is well to administer an emetic or purgative. Although opiates are generally used, Harley considers them contraindicated in the majority of cases of affections of the liver. If, however, the pain should become unbearable, a hyperdermic injection of morphine should be given over the epigastric region. Still he has the greatest confidence in the efficacy of belladonna not only taken internally, but also in the form of liniment, plaster and suppository. An alkaline water should also be given the patient, composed of say a teaspoonful of bicarbonate of soda in a glass of water, or half milk and half water. It is impossible, says Harley, to give the patient too much of this mixture, since it lessens the irritability of the stomach, facilitates vomiting, and favors the secretion of bile, thus materially aiding the expulsion of the calculi. It should not be neglected, also, to administer a mercurial purgative, the following being recommended:

℞ Hydragyr. cum cretæ,.....0.40 gramme.
Pulv. rhei,.....0.20 "
Magnesiæ,.....1.50 "
M.

Finally, Harley also claims to have achieved excellent results by digital manipulations and massage of the abdomen, as a means of causing the expulsion of gallstones.

The treatment of hepatic collic, as advocated by Prof. Lemoine, of Lille, and quoted in the *Revue Médicale*, March, 1891, is almost analogous with the above.

Internally, in the absence of emetics, he advocates potions containing ether or chloroform. Locally, over the seat of the trouble, he applies heat in the form of cataplasms. These should be very large, very hot, and renewed every hour. Frictions and rubbing with belladonna and chloroform over the hepatic region are also useful. Contrary to Harley, however, Lemoine has found that prolonged or oft-repeated baths produce a calmative effect which tends to hinder the expulsion of the calculi.

The following suppositories will be found most useful:

℞ Ext. belladonnæ,
Ext. opii, aa.....0.02 gramme.
But. cacao,.....6.00 "

These suppositories should be inserted every hour or half hour as occasion demands. The surest and most rapid method of relieving all pain is, however, by hypodermic injections of morphine; the pain disappearing in from five to fifteen minutes. About half a centigramme should be injected and repeated in half an hour if necessary.

For a purgative, Lemoine prescribes atropine with morphine in the following formula:

℞ Chlorhydrate of morphine,..... .10 gramme.
Neutral sulphate of atropia,.... .01 "
Cherry-laurel water,.....20.00 "
Mix.

Lemoine condemns the practice of inhaling chloroform or ether, claiming that it is apt to cause more harm than good. Neither should chloral be administered internally, it being badly tolerated.

THE THERAPEUTIC EFFECTS OF DIURETIN.

Reissler (*Vratch*, Nos. 46, 47, 1890, *Bull. Gén. de Théap.*)—The author has studied the diuretic effects of diuretin in healthy men, and he paid particular attention to its effect on the renal tissue; and he also studied its effects on the pulse and blood pressure. His experiments were made on a normal man, on four with heart disease, two with nephritis and one with cirrhosis of the liver. He arranges his observations into three divisions—before, after, and during the administration of the drug. The dose given in each case was one gramme, repeated to six grammes a day. The following results were obtained:

1. Diuretin acts incontestibly on the blood-pressure, raising it.

2. It is not solely a diuretic, but has a cardiac action.

3. The drug gives remarkable results, especially in those cases of asystole, which do not depend on insufficiency of the valves.

4. When the muscle of the heart is dis-

eased the effects of diuretin are less marked, especially its diuretic effects.

5. In acute nephritis its diuretic effects are more marked than in chronic nephritis. The albumen is never augmented even if the administration of the diuretin be continued.

6. In hepatic cirrhosis diuretin augmented the quantity of urine.

7. In healthy men the drug does not increase the diuresis.

ABORTIVE TREATMENT OF HERPES BY APPLICATIONS OF PURE ALCOHOL OR OF ALCOHOLIC SOLUTIONS.

Leloir (*La Pratique Médicale*, Feb. 17, 1891) has been able, in a number of cases, to completely abort herpetic eruptions of the lips by the local application of carbolized alcohol, in the form of compresses. This treatment, however, has not given satisfactory results in herpes of the genitals. The vesicles of herpes zoster are acted upon favorably, but the eruption does not disappear except in rare cases.

The influence of the treatment by alcoholic solutions is remarkable. Whether applied at the erythematous or at the vesicular period, the herpetic eruption is generally aborted, and this is accomplished very rapidly, usually in the course of a few hours.

Leloir employs alcohol in different forms. For example:

℞ Alcohol, 90 per cent.....25 drachms.
Pure resorcin.....30 grains.

He often replaces the resorcin by thymol (15 grains), menthol (15 grains) or phenic acid (3¾ grains).

Other formulæ are employed by the author, as follows:

℞ Alcohol, 90 per cent.....25 drachms.
Resorcin.....30 grains.
Chlorhydrate of cocaine..... 7½–30 grains.

℞ Alcohol, 90 per cent.....12½ drachms.
Tannin..... 1½ drachms.

In private practice Leloir uses this preparation:

℞ Alcohol, 90 per cent..... 25 drachms.
Extract of cannabis indica....2½ drachms.
Chlorhydrate of cocaine..... 15 grains.
Essence of peppermint.....2½ drachms.

Compresses, moistened with one of these mixtures, are applied upon the eruption, and are fixed by means of pieces of adhesive plaster, or, for the same purpose, collodion and medicated gelatine may be employed.

—*Univ. Med. Mag.*

HYDROCHLORIC PHENOCOL.

Dr. Hertel, in the *Wiener Med. Presse*, April 19, 1891, reports of the value of hydrochloric phenocol, a new antipyretic and antirheumatic. The drug is a white, micro-crystalline powder. Chemically, it is produced from phenacetin, which, by the introduction of the saline amido-group, is rendered soluble in an acetyl residue. Hydrochloric phenocol is soluble in water, forming a clear solution. The fresh solution is of neutral reaction. Solutions, two days old, show a slight alkaline reaction which increases with the age of the solution.

So far, the drug has not been found to produce any unpleasant effects upon the heart, lungs, or digestion, even when given continuously in daily doses of 5 grammes. Hydrochloric phenocol does not have any effect upon perspiration, neither producing nor increasing it. As a test for its antipyretic properties, Dr. Hertel used it in a number of cases of phthisis with irregular hectic fever. Single doses of 0.50 gramme will cause a fall of temperature of about ½° C. Doses of 0.5 gramme to 1.5 grammes, given hourly, will generally bring the temperature down about 1° C. but only for a short time. Single doses of 1 gramme will cause a fall of 1–1½° C. within a few hours. The fall of temperature usually begins within an hour after the exhibition of the remedy, and lasts for about two hours. Five grammes, in divided doses during the day, will generally suffice to keep the temperature down. It seemed, however, to rather lack in efficacy in controlling high evening temperatures. In severe cases of acute muscular rheumatism, often accompanied with serious after-complications, the drug is frequently of value in relieving pain, when other remedies, such as antifebrin, antipyrin, salicylate of sodium and phenacatin have failed. The dose given was 5 grammes daily. In these cases, however, the drug entirely lacked any antipyretic action, the temperature not sinking to the normal until the rheumatism and the accompanying symptoms began to improve. In cases of severe gonorrhœal rheumatism the drug has no influence either upon the course of the disease or upon the fever. Hydrochloric phenocol exerts no deleterious influence upon the kidneys, although after the ingestion of 5 grammes the urine becomes reddish-brown in color, or even dark brown. This discoloration increases materially if the urine is left exposed to the air. Liq. ferri sesquichlor. added to the urine causes a still darker coloring, which is con-

siderably lessened, although not dispelled by the addition of concentrated sulphuric acid. The drug is eliminated with great rapidity, since twelve hours after its exhibition it can be no longer traced in the urine. The technical name of the drug is *amido-acet-para-phenetidin.*

MEDICINE.

TREATMENT OF ERYSIPELAS WITH SALICYLATED GLYCERINE.

For the past six years Dr. S. C. Inglessis has been treating erysipelas successfully with a solution of salicylate of soda in glycerine. A four to six per cent. solution is used as a lotion, and rubbed into the affected parts every two or three hours, after which the parts are covered with salicylated cotton. Simultaneously, if there is no heart weakness or albumin in the urine, the author advises the exhibition of 0.2 grammes of salicylate of soda daily. In all, he has treated thirty-six cases with this method, and all successfully. The application of the salicylated glycerine caused an immediate disappearance of pain and itching, and considerably lessens the course of the disease. When instituted at the outset of the disease the treatment will frequently abort it, and cause an almost immediate recovery.—*Semaine Médicale.*

CRYSTALS IN NASAL POLYPI.

At the meeting of the Society for Internal Medicine of Berlin, held April 21, 1891, and reported in the *Médicine Moderne*, April 30, 1891, Dr. Lewry reported the results of the microscopical examination of a large number of polypi of the nasal mucous membrane. The polypi contained large quantities of a fluid rich in albumin, in which, after a variable length of time, but usually within a few days, there appeared crystals of a double pyramidal form, and resembling in every particular the crystals found by Dr. Leyden in the sputa of asthenatics. The formation of these crystals seems due to a necrotic process, since they only appear some time after the removal of the growths, and increase in number. The theory has been advanced that these crystals, forming in nasal polypi, might find their way down the respiratory tract, and act as a mechanical irritant, thus producing asthma. Lewry's experiments however, have confirmed beyond doubt, that the crystals do not exist in the polypi until some time after their removal. It is, however, very possible that their fundamental elements existing in the blood act as an irritant. The same crystals have also been found in non-asthenatic cases, but this is most rare. They have never been observed in the tonsils or uvula.

ON AMICRABIAN FEVER FOLLOWING ARTERIAL OBLITERATION.

It has been frequently observed by Gangolphe and Courmont (*Le Bull. Médical*, April 8, 1891) that arterial obliteration, without external lesion, is followed by a rise of temperature even above 40°C. In order to explain the cause of this phenomenon they have instituted a series of experiments upon the lower animals. The investigators have thought that the fever is due to a reabsorption of the products resulting from the cellular desintegration occurring in the parts deprived of blood, but in which a new circulatory process has been started and, thus enhanced, the taking up of these cellular products formed during the anæmic condition of the part. When, however, these products are not absorbed, as for instance in the case of elastic ligatures applied in the course of the experiments, no hyperthermic phenomena occur. These elastic ligatures were tried in the scrotum of the animals used, and were allowed to remain for three days, during which, no changes in the body temperature occurred. At the end of this time the ligatures were removed, and of course the new cellular products would find their way into the general circulation, with the result that the temperature was considerably elevated.

In some instances the organism in a state of necrobiasis, or degeneration, were removed and from them was extracted a substance insoluble in alcohol but soluble in water, especially glycerinated water. This substance was found to possess a pyretogenic power.

From the researches made, the authors have drawn the following conclusions:

1. The existence of amicrobian fever is proven, clinically and experimentally, in cases of vascular obliteration.

2. This fever seems to be due to the reabsorption of the soluble pyretogenic products resulting from cellular desintegration of the parts in state of necrobiosis.

3. The subsequent decline of temperature, occurring at the time of elimination, is due to the diminution of the necrobiotic process and to the lessening of the vascular interference.

4. These pyretogenic products exist in large quantities in degenerating tissues; they

are precipitated by alcohol but are soluble in glycerinated water.

SURGERY.

PLASTER OF PARIS BANDAGES.

According to the *Medicinische Neuigkeiten*, April 18, 1891, the proper preparation of plaster of Paris for bandages is not generally understood, and, therefore, the results obtained are frequently unsatisfactory. The fluid used should be filtered rain-water, or still better, sour milk. Either will make an extraordinarily hard plaster. The addition of fine marble dust will also add to the hardness. An addition of 33½ grammes of alum and 33½ grammes of sal ammoniac to each ½ kilogramme of the plaster is also recommended. The following directions for mixing are given: The plaster should be put in a dry basin and formed into a cone, and then water or sour milk slowly added until the fluid has been drawn up to the tip of the plaster cone, *then* begin to stir. In this way the best results are obtainable.

TREATMENT OF TRACHOMA.

At a recent meeting of the Ophthalmological Society of Paris, the question as to what was the most efficaceous treatment for trachoma was extensively discussed. Darier abvocates a thorough breaking up of the granulations by an operation under chloroform. The operation consists in a deep scarification of the conjunctiva and a subsequent scraping with the curette, and finally a brushing off with a very stiff brush soaked in a strong solution of bichloride of mercury. Within one or two weeks a fine cicatrical tissue is formed, without causing any deformity of the lids. Abadie has also used this surgical method for the treatment of trachoma with extraordinarily good results, such as he has never observed to follow any other treatment for this disease.

Gillet de Grandmont, was opposed to any surgical treatment, claiming that it sacrificed the continuity of the mucous membrane. He advocates the use of acetate of lead in the following formula:

℞ Plumb acetic..... ..... 2.0 grammes.
Glycerin, pur, anhydr.....10.0 grammes.
M.

This mixture should be applied by means of an antiseptic ivory spatula, and under its influeuce the trachoma disappears. This collyrium has no caustic action and therefore does not injure the conjunctiva or cornea.

Vigues strongly recommends the direct massage of the conjunctiva with applications of boric acid, and his statistics show that he has achieved brilliant results by this method, a few days sufficing to produce a marked improvement in every case.—*All. Med. Central-Zeitung*, April 22, 1891.

THE TREATMENT OF COLD ABSCESSES.

The treatment of cold abscesses by the antiseptic puncture is advocated by Piechaud (*Le Bull. Médicale*, April 8, 1891). The results of this simple procedure have been entirely satisfactory, no complications having followed the cures accomplished. The size of the abscesses treated has been variable, but the largest collections were met in the thigh and buttocks of children. The liquid of some of these abscesses showed, under the microscope, the presence of the streptococus and the staphylococus.

Twenty cases were treated as follows: After the puncture washing of the sac was ordered, and then the application of a solution of corrosive sublimate (1 to 1000) was made. This method usually brought about a very rapid cure, even in cases where the skin had become so thin as to threaten a rupture of the abscess. The author never observed untoward effects following the use of the mercurial solution employed.

GYNÆCOLOGY.

SALOL AS A DEODORIZER OF THE FŒTED DISCHARGES OF UTERINE CARCINOMA.

Drs. Marty and Plowezky, of Toulouse, recommended, in a recent number of the *Semaine Médicale*, the internal use of salol as a deodorizer of the fœted vaginal discharges in cases of internal carcinoma. The remedy is of especial value in cases when a vesico-vaginal fixtula exists, as the stench of the discharges of these cases is most sickening. The authors, arguing that in the organism salol would be split up into its two component parts, viz., salicylic acid and carbolic acid, gave the drug internally hoping to render the urine antiseptic. The results of their experiments exceeded their hopes, for in two cases, in which all the usual methods, such as vaginal injections of disinfectants, and tampons, had been tried in vain, salol given internally caused a complete disappearance of the fœted odor. The drug was given in doses of from two to four grammes daily. If this quantity was not

sufficient as much as six to eight grammes may be given daily without producing any unpleasant symptoms. Its action in cases complicated with vesico-vaginal fistula is most marked, the dribbling of the antiseptic urine over the carcinoma causing a continual process of disinfection.

INTRA-UTERINE GALVANO-CAUTERIZATION IN GYNÆCOLOGY.

Apostoli (*Bull. et Mem. de la Soc. de Méd. Prat. de Paris*, Feb. 15, 1891), in support of his electrical treatment, lays down briefly the following propositions: The galvanic current finds its principle indication in gynæcology in endometritis and fibromata; it is sovereign in circulatory and painful affections (amenorrhœa, dysmenorrhœa and metrorrhagia), and it is of powerful assistance in arresting the evolution of benign neoplasms, and in aiding in the reabsorption of peri-uterine exudations. It exercises a very salutary resolutive action in many of the peri-uterine phlegmasiæ and in catarrhal ovaro-salpingitis; but it is inefficient, and it may be even harmful in strong intensity, especially if the intra-uterine pole is negative, in the suppurating phlegmasiæ of the appendages.

In his justification of the application of high intensities, he claims that electrotherapy, as well as general therapeutics, should be essentially seasonable in its employment, and that its dose should be modified according to clinical indications, which vary in each instance. It has been necessary to employ the galvanic current in various degrees of intensity, in order to arrive at the most beneficial strength necessary to accomplish the desired object. In certain conditions high intensities of the galvanic current must be employed where weak currents will have no effect. The current should be increased in power progressively and with due warning to the patient. Every fluid collection, suppurating or bloody, uterine or peri-uterine, absolutely contra-indicates high intensity, while it calls for an evacuation more or less speedy, or for surgical extirpation. The current, however, in such cases acts as a valuable means of diagnosis, since relief not following its application, it will lead to the suspicion of a cystic condition which further examination will reveal. The positive pole of the constant galvanic current has, in addition, a powerful action in destroying microbes, especially the destructive bacteria.

The intra-uterine application facilitates the penetration *en masse* of the current, because the uterine mucosa of feeble resisting power will be readily traversed by the current. In cases of peri-uterine affections (para- and peri-metritis), if there be any resistance offered to the purely intra-uterine application, he claims immediate relief for the peripheral vaginal galvano-puncture. Patients thus treated have said that while "galvano-puncture has been the most painful operation, it has been followed by the most complete amelioration of the symptoms."

There is no danger of ultimate sterility from the intra-uterine treatment, since Apostoli has collected thirty observations of patients so treated who have gone to full term in a subsequent pregnancy.

During the eight years, from July, 1882, to July, 1890, Apostoli has treated 912 cases, consisting of 531 fibromata, 133 simple endometritis, and 248 endometritis complicated with peri-uterine phlegmasiæ (peri-metritis, para-metritis, or inflammation of the appendages). Eleven thousand four hundred and ninety-nine galvanic applications were made as follows:

8,177 positive galvano-caustics, intra-uterine.
2,486 negative " " "
222 positive vaginal galvano-punctures.
614 negative " " "

During this time he has had three deaths, the first due to a galvano-puncture made too deeply into the peritoneal cavity upon an extra-uterine fibroid; the second due to a puncture of an ovaro-salpingitis, probably suppurative (no autopsy was made). There had been an intestinal perforation. The third was due to a grave diagnostic error, where an ovarian cyst was mistaken for a fibroma and improperly treated.—*Univ. Med. Mag.*

OBSTETRICS.

THE ELIMINATIVE TREATMENT OF PUERPERAL SEPTICÆMIA.

From a study of infectious diseases in general, and from observations on the methods of elimination of toxic substances from the organism by the natural emunctories, Héliodor de Swiecicki (*Gazette hebdomadaire de médecine et de chirurgie*) advises the employment of these means to rid the system of poison in puerperal septicæmia. Of course, the early treatment of this disease, if the case is seen in time, is, first, by asepsis and antisepsis by means of uterine irrigation, etc.; and, secondly, by the use of alcohol and every means to prevent the poison from

overpowering the organism. But, if the morbid germs and their products have surcharged the blood, the author says, the production of exaggerated diuresis and diaphoresis would be a rational method of eliminating the morbid elements. The treatment consists of subcutaneous injections of pilocarpine and the drinking of large and frequent draughts of sterilized chloride of sodium solution. If there is any difficulty in the patient's swallowing the solution, it is to be introduced directly into the stomach by means of a tube. The author reports the success of this method of treatment in several grave cases of puerperal septicæmia. The amelioration of the symptoms was prompt, the temperature falling, the pulse becoming less rapid, and the rigors disappearing in a very short time. The patient must be watched closely for any sign of heart failure, in the event of which small doses of alcohol are to be given.

HYDRASTIS CANADENSIS IN UTERINE HÆMORRHAGES.

Jules Bataud refers to the paper by Schatz, and to the recent theses by Cabanès and Pigache, which contain a *résumé* of the recent literature upon hydrastis. Bataud himself has studied the effects of hydrastis in four cases of uterine hæmorrhage which occurred in the wards of the Saint-Lazare.

The first case was that of a prostitute, twenty-seven years old, with secondary syphilis, who was unexpectedly arrested while street-walking, and was taken to Saint-Lazare. She was of a very nervous and impressionable temperament. Menstruation was regular, scanty, and accompanied with dysmenorrhœa. The patient had never had a child or a miscarriage, and, though she had been at the hospital a dozen times before, had never had uterine hæmorrhage. At the time of admission it was found that she had an enormous papulo-hypertrophic syphilide of the vulva and anus. On the night of admission she was seized with profuse hæmorrhage from the uterus, preceded by dysmenorrhœal pains, though she had menstruated only fifteen days before. The cause of the hæmorrhage was thought to be congestion of the ovaries and uterus, induced by the shock of her sudden arrest—such an effect is said not to be uncommon in patients brought to Saint-Lazare. An examination of the uterus and ovaries showed no cause for the hæmorrhage. The patient was given ten drops of fluid extract of hydrastis thrice daily, and the hæmorrhage ceased nine days after its first appearance. It is not clear from the text whether she took the hydrastis from the beginning of the hæmorrhage or not. The drug was continued for twelve days after the hæmorrhage had ceased. The following menstrual period continued only three days, and the flow was scanty as usual.

The second patient, a woman, twenty-one years old, was admitted for gonorrhœal urethritis and vaginitis, with discrete vegetations about the anus and vulva. Menstruation was regular and painless, lasting four or five days. She had had neither children nor miscarriages. While descending the stairs, one day after admission, she fell, striking her side over the region of the kidney. Two hours later she was seized with acute pain, and was obliged to go to bed. The same night very profuse and painful hæmorrhage from the uterus came on. There was a large ecchymosis in the left lumbar region. Forty drops of fluid of extract of hydrastis were given daily, in four doses. The next day pain and hæmorrhage were less, and in five days from the beginning of the administration of hydrastis, and in six from the time of the accident, the hæmorrhage had ceased.

In the third case, a woman, twenty-three years old, was admitted for syphilitic erosions of the mouth. Her menstruation had always been regular, scanty and painless, lasting four or five days. She had had neither children nor miscarriages, and never had menorrhagia or pain in the abdomen until three months before admission, when she rolled down stairs. This accident was followed by a sensation of heat and weight in her abdomen. Two days later menstruation set in, and was painful and much more profuse than normal, and continued ten days. In the interval between her menses the pains continued, and leucorrhœa developed. The last menstruation before admission was similar to the one just described. The uterus, vagina, and vulva were intensely congested. The dull curette disclosed no lesion of the endometrium. At the next menstruation the patient was kept in bed, and was given forty drops of fluid extract of hydrastis a day, beginning on the second day after the appearance of the flow. Menstruation lasted only seven days, and was less painful. The hydrastis was continued until the next menstruation appeared, which was not painful, lasting only five days, and was not as profuse as before. The congestion of the uterus is said to have been completely cured.

In the fourth case, a woman, thirty-nine

years old, had been curretted eight months before for metrorrhagia due to an endometritis following abortion. The patient was cured by the operation, and menstruation became normal as to quantity and duration. On the second day of one of her menstrual periods, she had intercourse with her husband. Instead of the flow ceasing on the fourth day as usual, it continued for eight days longer, the patient suffering at the same time from sensations of heat in the pelvic organs. Bataud saw the patient on the tenth day of the hæmorrhage, and gave her four one-grain pills of hydrastin a day. The sensations of heat and the hæmorrhage diminished from the first, and ceased on the second day. Since then she has had two periods, each lasting only four days. Absence of endometritis was proved by curretting the womb. Hydrastin was used instead of the fluid extract of hydrastis, because of the disagreeable taste of the latter.—*Revue Médico-Chirurgicale des Maladies des Femmes.*

PÆDIATRICS.

MEDICINES TO NURSING MOTHERS; INFLUENCE OF THE MILK UPON THE INFANT.

Schling (*Gazette de Gynécologie*, Feb. 15, 1891—*Paris Médical*) has made a series of investigations with various medicines, and obtained the following results:

Sodium Salicylate.—Dose, fifteen to thirty grains. When the child was not put to the breast for an hour or more after the administration of the drug to the mother, it was always found in the infant's urine and disappeared in twenty-four hours. If the infant nursed very soon after administration, there was no trace of the drug in its urine.

Potassium iodide.—Similar results. Analysis of the milk gave the characteristic reaction. Elimination in the infant lasted seventy-two hours; in the mother, forty-four hours. After twenty-four hours the milk contained the drug.

Potassium Ferro-cyanide.—Reaction very plain in the mother's urine. None in the infant's.

Iodoform.—Employed as applications to the vagina and vulva. After a rather prolonged use, as a rule, iodine was found in the milk and the mother's urine, but never in the urine of the infant.

Mercury.—Its transmission through the milk was always very feeble and irregular, and depended upon the quantity of milk absorbed.

Narcotics.—(a) *Tincture of Opium*, in doses of twenty to thirty drops. Thornhill has observed in the infant prolonged sleep. Fehling has noted neither prolongation of sleep nor constipation. (b) *Morphine Hydrochlorate.*—Solution 1-30; doses, gr. $\frac{1}{6}$-$\frac{1}{3}$. No ill effects upon the child. (c) *Chloral.*—Dose, gr. xv.-xlv. Mean duration of maternal sleep, two hours. No action was noted upon strong and vigorous infants. When the child is feeble or premature there should always be an interval of at least two hours between the administration of the drug to the mother and nursing. (d) *Atropine Sulphate.*—Solution, 1–100. Subcutaneous injections, gr. 1–200–1–120. Pronounced symptoms were observed in the mother. Dilatation of the pupils was noted in the infant, which disappeared after twenty-four hours. The drug should not be given to nursing mothers except in very small doses.

Influence of Maternal Fever.—In an immense majority of cases the milk has no ill effects upon the child. When the mother was the subject of a grave disease with a persistent temperature of 104°, the fever curve of the infant presented the same characters as that of the mother. In a case of mastitis, Bumm has demonstrated the presence of micrococci in the milk and gastro-intestinal disturbance in the child.—*Univ. Med. Mag.*

ADMINISTRATION OF ANÆSTHETICS TO CHILDREN.

Dr. Ness, in a discussion published in the *Glasgow Medical Journal*, reports 1080 cases in which anæsthetics were employed at the Hospital for Sick Children. In all these cases careful notes were taken, and there were at least a thousand more of which no record was kept. Chloroform was almost invariably used, ether being employed only in exceptional cases. No death has ever occurred during the administration of an anæsthetic. The mode and details of administration are not given.—*N. Y. Med. Jour.*

THE PREVENTION OF OPHTHALMIA IN THE NEW-BORN.

Simeon Snell, in the *Lancet* says, this it appears established that the ophthalmia of the new-born is a disease which permits of distinct prevention, and that even careful cleansing with plain water is sufficient. There may be reasons against entrusting such a strong solution of nitrate of silver as Credé advocated to nurses, but a much weaker solution would suffice. It may, however, be perhaps as well to use some

antiseptic with the water employed for cleansing, in the manner used at the Jessop Hospital. Directions are now freely given to nurses and midwives as to the employment of antiseptics for the lying-in woman, and the sublimate solution freely ordered will do excellently for bathing the infants' eyes. Some of us who see the terrible effects of the disease are earnestly impressed with the importance of doing all we can to prevent its occurrence. As far as we are able we must spread knowledge as to the dangers of delay and the benefit resulting from early treatment. The obstetrician has, however, the opportunity of preventing the disease. The teacher can find occasion to bring the subject before his pupils, and the writers of text-books, whether for medical students, midwives, or monthly nurses, should urge the importance of the affection and give directions as to the means necessary for prevention. No text-book should, he thinks, be published without some such teaching. The disease is particularly met with among the poor—much less frequently among the well-to-do. Hence the importance of midwives, who by degrees are acquiring a better and more recognized status, receiving thorough instruction in the subject.

HYGIENE.

CORROSIVE SUBLIMATE AS A DISINFECTANT AGAINST THE STAPHYLOCOCCUS PYOGENES AUREUS.

Dr. A. C. Abbott, in a study of this subject in the Bacteriological Laboratory, in the Johns Hopkins Hospital, believes that the following conclusions are justified:

1. Under the most favorable conditions a given amount of sublimate has the property of rendering inert only a certain number of individual organisms. That is to say, the process is a definite chemical one, taking place between the protoplasm of the individual bacteria and the sublimate in the solution.

2. The disinfecting activity of the sublimate against organisms is profoundly influenced by the proportion of albuminous material contained in the medium in which the bacteria are present.

3. The relation between the golden pyogenic staphylococci and sublimate is not a constant one. organisms from different sources and of different ages behaving differently when exposed to the same amount of the disinfectant, for the same length of time.

3. The organisms which survive the exposure to the sublimate. may experience a temporary attenuation. This attenuation, however, may be caused to disappear by successive cultivation in normal media.

IMMUNITY FROM INFLUENZA OBTAINED BY VACCINATION WITH CALF LYMPH.

The *Medicinische Nenigkeiten*, April 18, 1891, speaks of the interesting researches of Dr. Julius Goldschmidt, regarding the immunity from influenza, or grippe, afforded with recent vaccination with calf lymph. Dr. Goldschmidt's attention was first called to the fact, when during the epidemic of influenza of 1890, there occurred also a good deal of small-pox in Madeira, and he was surprised to find that those whom he vaccinated escaped from the epidemic. In all he vaccinated 210 patients, in 112 of which the lymph took. Of the remaining 98, only 15 were seized with grippe, and then only in a very mild degree. In one household of twenty-six members, all who were not vaccinated had the influenza, and two of them nearly died, while twelve who had recently been vaccinated escaped. The author claims that the immunity to influenza shown by the majority of children is due to the fact that they have been more or less recently vaccinated.

At these times when the influenza seems again to be premeditating an extensive tour, these facts are not only of interest, but warrant our careful consideration.

MEDICAL CHEMISTRY

CONVENIENT URINE TESTS.

To test for albumin, Raabe uses trichloracetic acid in the following manner. (*Merks Bulletin.*) About one cubic centimetre of urine, previously filtered, is poured into a narrow test tube, and a small crystal of trichloracetic acid is dropped into it; it is then set aside for a while, without shaking. The acid soon dissolves in the bottom of the test tube, and at the plane of contact of the two layers of fluid a distinctly visible and sharply defined turbid zone forms, if albumin be present. Even the slightest quantity of albumin can be detected with certainty and promptness, because the contrast between the turbid zone and the supernatant clear fluid is very distinct. According to this author, trichloracetic acid produces no precipitation in normal urine. Only when the latter abounds in urates, a slight haze develops after some lapse of time;—this can

be avoided, however, by gently warming the urine, or by diluting it with three times its volume of distilled water. He ascertained, by comparative tests, that trichloracetic acid is decidedly more sensitive, as a test for albumin, than either nitric or metaphosphoric acid.

According to Roch sulpho-salicylic acid is a very sensitive and reliable reagent for albumin. It is a product of the action of sulphuric anhydride on salicylic acid. By its means, the presence of egg-albumin can be proved with certainty in a solution of one part of the latter in 20,000 parts of water. To test urine for albumin, all that is necessary is to add a few crystals of the readily soluble sulpho-salicylic acid to a few cubic centimetres of clear urine and shake. The appearance of turbidity indicates, with certainty, the presence of albumin; for all the other constituents of urine—such as peptone, glucose, urea, uric acid, etc., remain in solution; the albumin alone being precipitated by this reagent.

Certain substances which may be present in urine, such as arsenic, salicylic acid etc., may interfere with the test for sugar, by either the fermentation method or with Fehling's solution. In order to eliminate this source of error Bishop advises treating the urine as follows: The urine is first shaken with animal charcoal. As soon as the fluid appears colorless, add baryta water, boil, allow to cool, and filter. To the filtrate add cautiously a weak solution of cupric sulphate in moderate excess, allow to stand for one hour in a covered vessel, decant and filter. To the clear solution add H_2S water in excess, or better, transmit H_2S gas through the solution. Then filter, apply a gentle heat to expel the H S which may be present and again filter. The solution is now practically free from everything which would interfere with the determination of sugar, and the operation may be finished by either of the usual methods.

Nothnagel communicated at a recent meeting of the Vienna Medical Association, a paper received from Dr. Becker, of Cairo, on a simplified test for sugar, which depends upon the fact that the paper used for the manufacture of visiting cards contains a large quantity of potash to make it heavier and fuller. When this paper is brushed over with a concentrated solution of sulphate of copper and then dried, the salt is crystallized on the surface. If the urine containing sugar is then added by means of a bit of wood and allowed to dry by the action of the air, or by holding it over an Argand burner (without browning the sulphate of copper), the latter is liquefied by the water contained in the small crystals, and the alkaline paper immediately produces the sugar browning reaction. The more sugar the urine contains the darker the color produced. The author considers the test highly sensitive.

NEWS AND MISCELLANY.

HIGHER MEDICAL EDUCATION.

At the meeting of the Board of Trustees of the University of Pennsylvania, held May 21st, Dr. Pepper made an offer of $50,000 towards an endowment fund of $250,000, and of $1000 annually towards a guarantee fund of $20,000 annually, for five years, conditioned upon the establishment of an obligatory graded four-year course of medical study. This was accompanied by a communication from the Medical Faculty, pledging themselves to carry out this proposal, and to enter upon the four-year course in September, 1893. It was also reported that the members of the Medical Faculty had themselves subscribed $10,000 annually for five years to the endowment fund. The Board of Trustees expressed warm approval of the proposed advance in medical education, but postponed their assent until the success of both funds had been demonstrated.

The approaching completion of the fine Laboratory of Hygiene, built by Henry C. Lea, Esq., will render the medical facilities of this school unequaled. It is to be hoped that the neccessary pledges will be secured promptly, as the interests of the entire community are deeply involved in the success of this great advance, which will enable medical students to obtain a thorough practical education in every branch of their profession.

THE SUPPRESSION OF QUACKERY IN ITALY.

During the first half of 1890 the number of complaints of "illegal exercise of the healing arts" brought before the authorities was 843. In 325 of these a conviction was obtained; in 145 the accused were acquitted. What the result was in the remaining 373 cases does not appear, but it is satisfactory to see that at least a considerable proportion of the offenders were brought to justice. It is to be hoped that the penalties inflicted will be sufficient to deter not only the guilty persons themselves, but others from pursuing their evil ways.—*British Medical Journal.*

ARISTOL.

While possessing all of the virtues of iodoform, and many properties not claimed for the latter **ARISTOL** has **NO TOXIC INFLUENCE AND NO DISAGREEABLE ODOR.**

The efficacy of **ARISTOL** has been widely tested by physicians and surgeons. As a simple dressing it now **HEADS THE LIST OF LOCAL REMEDIAL AGENTS**, and the results obtained in the **GREAT VARIETY OF MORBID LESIONS** for which it has been employed, have been wholly satisfactory.

ARISTOL has been widely commended for its special adaptability to all surgical and pharmaceutical requirements. It may be used in the form of **OINTMENTS, CRAYONS, SUPPOSITORIES, BALLS, OILS, SPRAYS, COLLODIONS, POWDERS, PLASTERS, Etc.**, while it is equally suitable for **TAMPONS, BANDAGES, GAUZE**, and other topical appliances. Used as a powder, it forms **AN IMPERVIOUS ANTISEPTIC COATING**, which gives it an exceptional value in **ULCERATIONS, BURNS, Etc.**

ARISTOL has been used with unqualified satisfaction by able and experienced clinicians in **DERMATOLOGY, SYPHILOLOGY, GYNÆCOLOGY, OPHTHALMOLOGY, Etc.**, and in all of those diatheses in whose course such lesions supervene as call for **ACTIVE, LOCAL MEDICATION.**

ARISTOL is demonstrated to possess **EXCEPTIONAL EFFICACY AS A CICATRISANT.** In **ULCERATIONS**, of whatever character they may be, in **BURNS**, and in **ALL OPEN LESIONS**, the efficacy of **ARISTOL** cannot be overestimated.

Hence its great value in the **DERMATOSES**, the **SOLUTIONS OF CONTINUITY** dependent upon **PHTHISIS, SCROFULOSIS, SYPHILIS, VARIX** and accessible **TRAUMATISMS**, and in the **SUPPURATIVE LESIONS** following many inflammations. Its value in **BURNS**, as in all the operations of **MINOR SURGERY**, is exceptional, while in **DENTAL SURGERY** it has given very valuable results.

Applied to the **MUCOUS SURFACES** of the **NATURAL CAVITIES**, in such conditions as **PHARINGITIS, RHINITIS, OTITIS METRITIS, URETHRITIS**, etc., etc., **ARISTOL** gives the same excellent effects as in tissue lesions.

☞Physicians are respectfully requested to test for themselves the accuracy of these statements, while reading in our pamphlet of the results obtained by others. *Pamphlet mailed to applicants.*

The preparation of **ARISTOL**, theoretically simple, involves the greatest care and experience, and the word "**ARISTOL**" is the registered property of *The Farbenfabriken, vormals Friedr. Bayer & Co., in Elberfeld.* In order, therefore, to secure the desired effect of **ARISTOL**, it is important that the physician be certain that the article used bears the name of these manufacturers, together with the name of W. H. Schieffelin & Co.

W. H. Schieffelin & Co.,

Clinical Lecture.

AMPUTATION BELOW THE KNEE—ARTIFICIAL ANUS—SARCOMA OF SHOULDER—RADICAL CURE OF HERNIA—CARCINOMA OF BREAST; REMOVAL—TUBERCULAR ARTHRITIS OF KNEE-JOINT; EXCISION OF KNEE-JOINT.

BY J. WILLIAM WHITE, M. D.

PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

AMPUTATION BELOW THE KNEE.

Gentlemen:—Our first case this morning is an old one, which I operated upon in last Wednesday's clinic. I bring the patient before you to-day merely to show you the result of the operation, which—as you will remember—was an amputation of the leg, below the knee.

You see the results, so far, are perfect. Not a drop of pus has formed; and from the one remaining drainage tube there has been only a slight serous discharge. The largest part of the wound has healed by first intention. The flaps are also of good color, and apparently well nourished. The patient has only had an immaterial rise of temperature, has a good appetite and looks well. Had this been an ordinary amputation, these results would naturally have been expected, since the operation was conducted antiseptically. But the young man you see before you was brought here for operation in an apparently moribund condition, suffering from an aggravated case of gangrene following a crush of the leg, and to get my flaps I was forced to go dangerously near the diseased parts. The results are a surprise to me, for at the time of the operation the patient's chances for recovery were very slim. Even now we cannot feel justified in giving an absolutely favorable prognosis, although the probabilities are that a complete ultimate recovery will be the result. This case is an example of the value of antiseptic surgery even in cases already gravely infected. Not only can we almost invariably prevent septicæmia or gangrene—but even when those conditions pre-exist, can frequently check their course. Such results as these are always most gratifying.

ARTIFICIAL ANUS.

I shall as quickly as possible show you the results of the other operations I performed at the last clinic. I am glad to be able to report that all are doing excellently well; not a drop of pus in a single case.

This man was operated upon for carcinoma of the colon. His condition was truly a pitiable one. Besides the colon being carcinomatous in almost its entire length, he also had a recto-vesical fistula, and was passing fecal matter through his bladder. His sufferings were intense. I performed colotomy, opening an artificial anus in the left groin. The patient is now doing well; he has had several large and comfortable stools through the artificial anus, and the fecal matter in the urine is growing less. What is now in the urine is probably from feces that were in the lower part of the colon before the operation, and will soon disappear.

Of the course this can at best be only considered a palliative operation, but it prolongs life and alleviates suffering.

SARCOMA OF SHOULDER.

This is also an old case, and has been doing remarkably since the operation, which was performed a week ago. The case was one of sarcoma of the shoulder. The growth was an enormous one, involving the shoulder joint and humerus, necessitating a very large wound and making the operation a formidable one. To-day you see that the wound has entirely healed by first intention with the exception of one point in the track of a drainage tube. There has been no pus, and no material elevation of temperature. The patient's condition is excellent, and she is now practically out of danger.

RADICAL CURE OF HERNIA.

The last of the cases operated upon last week was that of this man, over 70 years old, who had a very large irreducible hernia. It was undoubtedly the worst case I ever operated upon. The results of the operation can be fairly called perfect. Healing has been entirely by first intention, and there is no evidence of any return of the hernia. This slight swelling over the wound is due to œdema, not to a return of the hernia. Whether or not the operation will prove itself truly a "radical cure" remains yet to be seen, but the prognosis is undoubtedly good.

CARCINOMA OF BREAST.

The first case for operation to-day is one of carcinoma of the breast. The patient is a woman fifty-four years old. Before proceeding to the operation let me tell you that the two kinds of growths most frequently met with in the breast, are sarcoma and carcinoma. The following points are valuable for differential diagnosis. Sarcomata are soft; they occur before or during the middle of life; the skin is free and not involved, except that there is usually a venous enlargement. Carcinoma, on the contrary, usually occur late in life; the skin is adherent; the growth is hard, and frequently nodular, and the nipple retracted.

The latter symptoms are all present in the case before us.

The first step of the operation is to make two superficial incisions across the growth in the form of a crescent. We then proceed to dissect out the growth. One of the superficial incisions should extend well down into the axilla to facilitate the cleaning out of this part. Never run the risk of including diseased tissues in your flaps, or in your fear of removing too much and leave infected tissues behind. Also never fail to remove such portions of the pectoral muscles as are attached to the tumor.

One part of this operation which, for a subsequently successful result, requires the utmost care, is the thorough cleaning out of the axilla. In these cases the neighboring lymphatics are always infected and should therefore be carefully removed. This part of the operation is also by far the most difficult. Over the pectoral region we are comparatively safe, no large blood vessels being near, but here, in the axilla, we are working among a net work of large veins and arteries. You see I not only remove the lymphatic glands, but also any loose pieces of fat or tissue; in fact clean the whole axilla out, leaving nothing that might act as a seat for further infection.

Having now removed the growth, I bring the edges of skin together, and find that they approximate nicely. The wound is now closed with a row of sutures and dressed antiseptically, all bleeding points, which during the course of the operation have been caught by hæmostats, having been tied.

Before going to the next case, let me reiterate the necessity of removing all diseased tissue. It matters but little whether the wound is entirely covered by skin or not, but it is of the greatest importance that every particle of diseased tissue be removed, whether it be muscle, or gland, or skin. Unless this is accomplished, your operation will be worse than useless.

TUBERCULAR ARTHRITIS; EXCISION OF THE KNEE-JOINT.

The history of the young woman before us is one of tuberculosis. Several members of her immediate family have died of consumption. The patient herself has been suffering from an enlargement of the knee for some time, and has faithfully tried various methods of treatment, including the rest cure. But to no avail, and she is now practically a cripple, being unable to use the limb in any way. From the family history and the local evidences, the case is evidently one of tubercular arthritis of the knee-joint and we will excise the joint.

You see I elevate the limb as high as possible to render it bloodless. This is often a more satisfactory procedure than applying an Esmarch bandage in such cases, as forcible pressure could very possibly rupture a distended capsule and drive tuberculous or purulent material into the tissues above the joint. Indeed, I have not unfrequently seen this to be the case, and serious suppuration follow in consequence. Then again, there is nothing to be gained by the application of the bandage, since the limb can be rendered equally bloodless. This being accomplished we now place an Esmarch tube above the knee to control all possible hæmorrhage.

The operation of excision of the knee-joint consists in making a straight incision across the joint, turning up the flaps; removing of the patella; sawing off of the condyles; a thorough cleaning out of the joint; drainage; an antiseptic dressing, and the application of a suitable splint.

After having made my superficial incision, and having removed the patella by severing its tendenous attachments, I find that

the under surface of this bone is necrosed. The head of the tibia is also badly diseased, as are also the condyles of the femur. I find a large mass of synovial tissue and other evidence of tuberculosis. This confirms our initial diagnosis of tubercular arthritis of the joint. I am careful to remove all these infiltrated tissues, since if left behind they would undoubtedly be new foci for an extension of the disease. I divide the lateral ligaments freely. I saw off a good deal of bone from both the head of the tibia and condyles of the femor, three quarters of an inch at least, on account of the necrosed and softened areas which extend beyond the surfaces of the bones. You see these fresh bone surfaces look healthy, and straightening the leg, I find that they fit snugly together, leaving the limb in a more normal position. This operation is now practically completed, care being taken that all loose tissue is removed. Personally I prefer to ligate all bleeding points, but many operators depend merely upon pressure and elevation for the arrest of hæmorrhage. The wound may now be closed, an antiseptic dressing applied, and the limbs placed in a well-padded Gooch's splint. The prognosis is good.

THE TREATMENT OF SYPHILIS.

BY R. W. TAYLOR, M. D.

CLINICAL PROFESSOR OF VENEREAL DISEASES AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

Gentlemen:—I will now present to you a man with the characteristic rash of a secondary syphilis. He is 24 years of age, who had a gonorrhœa, a few months ago for the first time, and a chancre seven weeks ago, with no history of the period of incubation.

I wish now to speak to you a few words on the proper way of treating syphilis. In the first place, do not treat the initial lesion by the use of strong caustics, cold water dressings, lead water, lime water, or the black or yellow wash. Always bear in mind that absolute cleanliness is the true foundation of all treatment. When there is any tendency to ulceration in the lesion, by burning the parts vigorously you only cause the inflammatory areola to break down in ulceration at a later period. The very best remedy to use for the initial lesion of syphilis of all that I know of is iodoform, and you get that in the pleasantest form possible, under the name of Merck's iodoform. I wish to give you a point in this connection. We hear a great many people say that they cannot use iodoform on account of its odor, and it will be smelled by everybody. If you use iodoform carefully, and in small quantities, people will not be able to detect its presence. In other words, when you are dressing a chancre with iodoform, be careful that the iodoform does not get on the clothes of the patient, put on only sufficient to cover the sore, place a piece of cotton over that, and then draw the prepuce forward over the cotton. Then you can use iodol or aristol, if you choose, instead of iodoform, but neither of these is as good for this purpose as iodoform. Aristol is a good remedy to employ where there is not a very active stage of ulceration present.

If there is a good deal of hardness present and the chancre is "lumpy" it is well to wash the parts first with soap and water, and then with a five per cent. carbolic acid solution, dressing it with blue ointment.

When a man comes to you like this one, it is your duty to make the unpleasant fact known to him that he has syphilis as gently as you can, but with all the seriousness that the case demands. Impress upon him the necessity of his continuing under treatment for the next two years at least, and, in the majority of cases, you will find, if they start in with a good constitution, they will come out cured of their trouble at the end of that time. The idea that syphilis is an incurable disease is based upon the information that there is a diathesis behind all the stages of this affection which we are powerless to treat, and that our therapeutic measures are utterly useless in this respect. There are some cases, however, that will act badly, but by care and attention, and with a knowledge of the proper remedial agents, you will be able to tide them over their difficulties in time. Then again, there are other cases that, even with the best of care and attention, this diathesis seems to get the better of them and obtain complete mastery for a long period of time. You must bear in mind that syphilis is a constitutional disease, the tendency of which is to lower the vital powers and develop certain lesions which may be the means of producing invalidism in your patient and perhaps death. It behooves people, therefore, who have syphilis, to put their house in order, so to speak, and keep their health up to the highest possible standard of development. This is in reality the keynote of successful treatment

in these cases of syphilis. A man came to my office the other day with a minute chancre of the upper lip, so slight as to be hardly recognized from a herpes. He had enlarged submaxillary glands also. He told me he had a project by which he could make a large amount of money, and he wanted to know if I thought he would be able to undergo a certain amount of mental strain which this scheme would devolve upon him. I told him practically no, and informed him that he was in a condition in which he was not warranted to draw upon either his physical or mental resources. That it was his duty to husband his vital forces and not draw upon them for present use. If a man worries and bothers himself about the business and cares incident to a financial life, while under the influence of the syphilitic infection, you can well understand that this strain upon his nervous system is going to do him harm, and your treatment of his case by the therapeutic measures at your command will not result in much practical benefit to the patient. In treating a patient with syphilis put him into as good a mental and physical condition as possible, for, bear in mind this one fact, that the effect of the mind on the malignity of syphilis is very great indeed.

If your patient be a drinking man he must stop this habit, but it does not follow because a man has syphilis, you shonld teach him prohibition doctrines. There are a good many of those men who are accustomed to the use of a glass of beer or ale, and there is no valid reason that they should not be permitted to take a glass or two a day, if they want to. They should be advised to go to bed as early as practicable, avoid catching cold and over-fatigue. In other words they must not put their mental or physical qualities to the test in the way of over-fatigue or over-exertion. Time and time again can I look back and see children grow up to puberty vigorous and healthy, both mentally and physically, whose parents I have treated for syphilis years ago. It is always well to impress these patients with this hope of an ultimate cure, because there are some whom you will find it difficult to keep under treatment and observation for a proper period of time.

If a patient with syphilis has some little functional trouble, as for instance, a bronchitis, look out for that trouble. Having this chronic infectious disease he is very liable to have some pulmonary trouble added thereto. It is always well for a patient with syphilis to guard himself against exacerbations or development of that infection and in that way he will avoid the complications of the disease.

Some of you, no doubt, have read in the books that syphilis is largely a mathematical problem, and by regarding it as an abstract factor, they compute in figures the amount of mercury required for this abstract problem. This is a very routine way of treating this disease. Every case of syphilis is a law unto itself, and a dose which affects one man favorably, will affect another man unfavorably. A dose which will remove the poison in one patient will prove utterly powerless in another.

In the case of this man before us who presents with the first general manifestations of the disease you would not give him iodide of potassium. This drug is contra-indicated in the earlier stages of syphilis, except there be some severe trouble of the brain or periosteum. The proper way to treat this man would be to give him a pill of the proto-iodide of mercury, for of all preparations of this drug for internal use the proto-iodide of mercury is the best.

There is no necessity for the use of any tonic in this case, though in a good many patients you will find it very essential. As a general formula you will find the following a very good one:—

℞

Hyd. protoiodidi	viii gr.
Ferri et quin. cit	ʒ jss
Ext. Hyoscami	vi gr.

M. ft. Pill xxxii. S. Three a day.

If under the use of this medicine the glands are going down the remedy is doing your patient good, and you ought to keep him on this treatment for a month at least, but, if on the contrary, the remedy was not acting properly and your patient was not showing any signs of improvement under its use, then you can increase the dose of mercury to be given each time. You will rarely have to give more than three grains of the protoiodide of mercury a day and four grains will be the maximum amount you should give in the twenty-four hours, for if you do not produce the desired effect with that dose, you are not going to produce it all. At the onset of the disease it is well to give large doses of this drug and always inquire of your patient how it is acting. Ask him how he is feeling, whether he is losing or gaining in weight, whether his thoughts are clear and capable of the same amount of mental strain as before the onset of the disease, and these points in the treatment of syphilis will be a guide for you in your medication of the patient.

Some people will tell you that the guide to the availability of mercury depends entirely on the mouth. Such a view as that is erroneous. If, after the use of mercury for two or three weeks, you observe the condition of the gums and find any trouble there, touch them with the solution of iodine and keep up the use of the mercury. The mouth often becomes irritated by reason of defect in it, and the mercury will be well borne and produce its physiological effect if you keep the mouth in a good state. It is always a good plan to make peace with the mouth under these circumstances. The tests of the efficiency of your mercurial treatment is then the rapidity with which the lesions of syphilis vanish. It is well to give your patient for the first two or three months the protoiodide of mercury and then stop for a while, giving him the iodide of potassium and the tincture of gentian for a week or two. If in the early stages of the disease you cover four, five or six months with your treatment, you are going to cure your patients more efficiently than by giving them an interval of rest in the early stages of the disease. Every day during the first year of syphilis is a matter of vital importance, for during this time the disease is more amenable to treatment than at any other period of its history. Keep these patients as persistently and as constantly as you can during the first six months under the use of the mercury. Old Ricord used to say that he could cure syphilis in six months. In many cases he no doubt would, because he would keep the patient continuously under observation and treatment.

There is a limit to the use of the protoiodide of mercury in syphilis. It is well to give it for the first month or two and then to use inunctions of the mercurial ointment And here let me in this connection say a word about the use of the pill. hydrargyri. The blue pill is about as uncertain and capricious a remedy as you can get. It simply amounts to this, that when it is pushed on the patient, it will produce salivation as rapidly as possible, but when it is acting blandly, it is doing nothing at all. It is one of those drugs that you do not know in what way it is going to act. I have studied this subject with great care for many years, and I may say this, that the therapeutic effect of the protoiodide of mercury after two months of the disease is absolutely nil. It seems to develop in the system of the patient a tolerance for the drug, and possesses for no longer period the power of dissolving, destroying, or burning up these small round cells which constitute the evidence of syphilis. Therefore, after having given these pills for the time I have stated, then begin with your inunctions of the mercurial ointment. Take thirty, forty forty-five grains of mercurial ointment and have it thoroughly rubbed into the arm, having previously washed it with soap and water and then with a solution of carbolic acid. As the disease commences around the blood vessels in its permeation through the system and the lymphaties are its chief channels of distribution it is, therefore, always well to act on the glands whenever you can do so. Therefore, have the axilla well washed out and the ointment well rubbed in there. If you see any irritation over the parts cover it with Laselle paste which is composed of two parts of starch, two parts of oxide of zinc, with four of vaseline, to which may be added four or five per cent. of carbolic acid. In that way you will keep down the dermatitis. In giving the ointment, it is a good thing to have the whole neck up to the scalp rubbed in with these inunctions, for in that way you bring the mercury in contact with the whole surface of the body. You are in this way accomplishing two things, you are destroying those small cells that develop in the skin, and you are, at the same time, permeating the skin with the mercury which is producing its effect on the glands. It has been shown that by excising portions of the skin near the genitals in parts remote from the seat of the initial lesion you find small cells in the skin under the microscope. Therefore, you should bring your mercurial ointment into direct contact with the whole skin. You can cover the whole body in seven or eight rubbings, but these rubbings must be done faithfully and intelligently. Having gone over the whole body it is well to give the patient rest for three or four nights, and while he is taking the inunctions it may be advisable to ask him if his mouth is sore, if he has a diarrhœa, or pain in the stomach, does he sleep well at night, and is he nervous or depressed. If he replies no to these inquiries, then that is all right, and you are treating his syphilis efficiently. Continue with your inunctions till you have given your patient forty or fifty rubbings, and as a general thing, thirty-five or forty grains of mercurial ointment, will be sufficient. In this city, however, a patient cannot stand that amount of mercurial treatment, but if he were out in the open air with nothing to do and free from care and busi-

ness, he can stand a good deal more of this kind of treatment than if otherwise situated. There is no law regulating the amount of mercurial inunction you use in a given case to guide you but your own judgment. If your patient be a poor, weak, individual, perhaps twenty-five grains of the mercurial might be enough, and if he be a robust, vigorous man, he may require as many as sixty grains. It is always well to wait, before giving these inunctions, till the secondary symptons begin, so that you may know where you are, except where the lesion may make its appearance on the mouth or face of the patient and proves to be a menace to the health of those that surround him. While you are giving these inunctions, you can make use of the stomach for the purposes of tonic treatment. In giving these patients treatment, impress upon them the absolute necessity of rest and recreation. During the summer have them go away to the country as long as possible, and as an aid to the inunction treatment, let them take very hot baths in order to produce free diaphoresis, or have them go to the Turkish baths. Stimulating the circulation and producing diaphoresis in this way seems to scatter the mercurial ointment throughout the system.

In some cases you will find that regional treatment is necessary, and it may be necessary to have certain parts covered with the ointment all the time. Push this treatment on for the first year with the mercurial.

But suppose that your patient cannot use mercurial inunctions, what then is to be done? In such a case as that you have a sovereign remedy in the injections of mercury. There is no preparation that I have found, and I have been using it now for over 23 years as an injection, that has given me better results in this respect than the bichloride of mercury. Get an ordinary hypodermic syringe, keep it in the cleanest possible condition, cleanse the surface of the body you are going to inject, and then inject under the skin one-sixth, one-eighth or one-twelfth of a grain of bichloride of mercury in ten minims of water, and in that way where the stomach fails, where the inunctions are inadmissible, you will find that you have a remedy that will not disturb the stomach, and will affect the syphilitic infection favorably, while at the same time preserving the stomach for the use of medicines that will build the patient up. I never experienced so much difficulty in the treatment of these cases as I have had this winter, and have found great help from these injections.

Now to sum up the treatment of these cases, I would say push on for the first year your mercurials, giving your patient a couple of weeks rest after the first six months, and then toward the end of the first year you can use your combination of mercury and iodide of potassium, or the so-called mixed treatment. The following formula you will find very satisfactory:

℞ Hyd. Iodidi,.....iij to ix grains.
Potass. Iod.,.....iv ʒ to vi ʒ.
Aquae. ad,.....ʒ iv.
M. and S. A tablespoonfull three or four times a day as the case requires.

Push this treatment on the second year, and you will generally find that your patient will be cured. In the vast majority of cases you will have the best result follow such a treatment as I have here given you in cases of syphilitic infection.

COMMUNICATION.

THE SPECIFIC AND THE NON-SPECIFIC TREATMENT OF PULMONARY CONSUMPTION.[1]

BY THOMAS J. MAYS, M. D.
PROFESSOR OF DISEASES OF THE CHEST IN THE PHILADELPHIA POLYCLINIC.

It goes without saying that the successful treatment of pulmonary consumption depends entirely on a correct and rational view of its origin. On this ground, there can be no division of opinion. Unfortunately, however, one part of the profession holds that the tubercle bacillus is the sole cause of the disease; while the other part believes that the disease depends on numerous other causes, and that the bacillus is merely one of its products or concomitants.

Now, it must be confessed that diametrically opposite opinions on a question of such tremendous practical and public importance, is no great credit to a profession which is justly proud of her logical conquests, and which rightfully rejoices in her scientific achievements, and in her work of philanthropy. Especially is this a misfortune when we consider that the whole difficulty rests on an erroneous interpretation of the fundamental terms which are involved in

[1] Read before the meeting of the Pennsylvania State Medical Society at Reading, June 3rd, 1891.

the question; and in endeavoring to prove this, I desire it to be perfectly understood at the outset, that I yield to no one in my admiration of, and I might even say in my veneration for those pains-taking explorers who so patiently and assiduously devote their life and energies to the investigation of this fearful malady. But I do not regard this as a question of personal reverence. It is one which must determine the true relation of the consumptive to his family, to his friends and to society; whether or not he is to be looked upon as a center of infection, a source of danger, and liable to spread the disease among those who are well.

Where then lies the fundamental misapprehension? It is (1) in affirming that, because a disease is capable of being communicated from one animal to another through inoculation, that, therefore, it must be contagious or infectious among the human species; (2) in holding that the disease (tuberculosis) which is produced artificially in animals through inoculation, is the same as that (consumption) which is naturally produced in man; and (3) in assuming, that, because an immunity can be created in animals by inoculations with a modified form of the tubercle virus, the same can be done in man. Furthermore, there is no warrant for believing that a disease can be cured by antogonistic inoculation unless it is clearly infectious or propogated from man to man through contagion.

The whole inception and progress of the infectious theory of consumption rests on animal experimentation, and recent history still reverberates with the assurances that the key to the cure of this disease was lying waiting in the lap of the experimentalists, whose dicta were to be blindly accepted whether they accorded with clinical experience or not. I am a firm and positive believer in the immense good which comes from well conducted laboratory research, and I think I have given sufficient practical evidence of my high appreciation of such work; but I also recognize the fact that the great bane of modern medicine is the tendency to subscribe to the premature conclusions of experimentalists which are wholly unsupported by bedside experience.

Professor Semmola of Naples, Italy, well strikes the key-note of this error, when he says (*Med. Press and Circular*, Feb. 25, 1891, p. 195): "It is painful to see these men carried away with this enthusiasm of Koch's fluid when they know that such a wide gulf exists between theory and practice, and when the very laws of scientific pharmacology and rational therapeutics are violated. The mistake exists in neglecting to see the gulf that lies between the laboratory and the clinic where all such fine dreams are blasted."

I am free to say that the mortification of professional pride, and the shock to public confidence recently perpetrated in the name of a specific cure for consumption, would all have been saved if we had raised our standard of treatment higher than the walls of the laboratory, and planted it on the solid and rational ground of practical experience.

I am not unmindful, however, that those who indorse the contagion theory claim that aside of experiments on animals, there is ample clinical evidence to justify their belief. Let us briefly examine these claims. Their chief argument is the work of Cornet, who investigated the death-rate from consumption among the nursing members of the Catholic convents and monasteries in Prussia, and found that this disease causes 62.88 per cent of all their deaths (*Zeitschrifte für Hygiene*, vol. vi, p. 65). This is, indeed, a high death-rate, but it does not demonstrate the contagious nature of consumption. It merely shows, what was well known before, that this disease prevails largely among those who lead indoor and confined lives. According to Dr. Baer's research (*Ueber das Vorkommen von Phthisis in dem Gefäugnissen*, 1884) the death rate from consumption among German prisoners is greater—ranging from 64 to 90.9 per cent. Another point which destroys Cornet's conclusions entirely, is forcibly brought out by Dr. Baer's statistics. These show that prisoners who suffer solitary confinement, and who have, of course, no personal contact with any outside sources of the disease are more vulnerable to consumption by 20 per cent. than those who are allowed to associate with each other.

Another argument is that houses in which consumptives died are centers of infection. This is principally based on the research of Dr. Flick, who believes from his investigations, that 20 per cent. of the houses in the fifth ward of the city of Philadelphia are so infected. It is interesting to observe, however, that Dr. Flick's conclusions are not corroborated by other observers equally competent who have studied the question of house infection. Dr. Langerhans, who practised medicine for nine years in Madeira, an island which is visited every winter season by about 400 consumptives, states (*Zur Aetiologie der Phthisie*, Virchow's Archiv. 1884, vol. 96. p. 289) that these invalids are

lodged, boarded, and in great part nursed by English colonists, varying from 210 to 250 in number, who live in about 100 houses. The rooms which are occupied by consumptives in the winter, are reoccupied by the resident families during the summer —thus insuring the closest intermingling of the well with the sick. House infection should certainly make its influence felt here, but the health records which have been accurately kept since the year 1836, show that only four of the English colonists died from consumption during all this time, and that one of these suffered from the disease before he came on the island.

Dr. Adams, of Colorado Springs, states in a private communication to me, that Colorado Springs has been a health resort for about seventeen years, and comprises about 11,000 inhabitants, and that the majority of the rooms in the boarding houses are, and generally have been constantly occupied by consumptives. Yet, after a diligent search among the physicians of that place, some of whom resided there from the first, he could only find a record of seven cases of consumption which originated there during this time; and so far as he could ascertain, none of these were especially exposed—at least none were husband, wife or sister who had charge of another consumptive.

Dr. Haupt, one of the resident physicians of Soden—a beautiful watering resort for consumptives, in Germany, says that there are one hundred and one families, whose members with the aid of servants, lodge and nurse consumptives and other invalids during the summer seasons. During the winter the same rooms are reoccupied by the members of the landlord's families. This has been going on for 33 years, and during this time there were exposed to this contagion, if so it may be called, 653 persons, fifteen of whom died from consumption, but in most of these the source of the disease was traceable to inheritance, to colds and exposure, but none of them to contagion.

Now when these facts are connected with other well known facts, such as the statistics of the Brompton Hospital for Consumption in London, and the Friedrichshain Hospital in Berlin, which fail to show a single case of contagion among 262 physicians and clinical assistants, and 1017 nurses—the former during 36 years and the latter during 16 years; the declaration of Dr. Detweiler, that during 14 years not a single case of consumption was contracted among the nurses and employees in his hospital for consumptives at Falkenstein; or the fact that among a collection of sixteen hundred and twenty-six cases of consumption among married people (for particulars I refer to my address on Hygiene published in last year's Transactions of this Society) the same disease existed in both couples only in 44 instances. I think no further proof is needed to demonstrate that consumption is not propagated from person to person through contagion.

I hope I shall be the last one to deny to my colleagues on the other side, the same honesty and conscientiousness of purpose as I ascribe to myself; but should this make me willing to brush aside this weighty mass of clinical testimony which is diametrically opposed to the contagion doctrine, and to accept as my guide, principles of treatment which are conceived in theory and born of fancy, and which have nothing to support them in bedside experience? He who has been a diligent observer during the last ten or fifteen years, must be aware by this time that every specific measure which has been proposed for the cure of consumption, from benzoate of soda, and hot air inhalations to tuberculin, has been a dismal failure, in spite of the fact that they have all been shown to possess strong anti-bacillary powers. Glance at the beggarly results which have been obtained from tuberculin. According to recent official reports,[1] fifty-five in number, issuing from the clinics, polyclinics, and pathological institutes of the Prussian University, only about one per cent. (10) of 932 consumptives, who received the specific treatment were cured. This is, indeed, a very diminutive proportion of cures when we reflect that all but one of the latter were in the first stage of the disease. There cannot be the least question that so far as the treatment of consumption is concerned, the bacillus theory leaves the profession exactly on the same level which it occupied ten years ago. Not only did it not advance the interests of pulmonary therapeutics, but it deflected research into channels of error, and served as a barrier to an investigation of the true causes of consumption.

Let us now relinquish the gloomy side of this picture and turn to the hopeful experiences of those who practically disregard the teachings of the bacillus theory, and treat the disease according to its clinical indications. First of all I shall refer to the experience of the late Dr. Brehmer in his world renowned institution at Görbersdorf, in Germany. In 1887 he gives the statistics of

[1] *Die Wirksamkeit des Koch's schen Heilmittels gegen Tuberculose.*

150 cases of consumption which he treated, 12 of whom were in the first; 80 in the second; and 58 in the third stage. Of these, 15.3 per cent. were cured, and 11.3 per cent. in whom the disease was arrested. Of those in the different stages he cured 50. per cent. in the first, 20. per cent. in the second, and 1.7 per cent. in the third stage of the disease.

In 1888, he gives the statistics of 554 cases which he treated, of whom 49 were in the first, 310 in the second, and 195 in the third stage. Of those in the first stage he cured 36.1 per cent., in the second, 9.7 per cent., in the third, 0.5 per cent.

The results reported in the Sixth Annual Report of the Adirondack Sanitarium, under the supervision of Dr. Trudeau are not less encouraging. Fifty-two patients were treated in the following stages: 21 in the first, 18 in the second, and 13 in the third. Of those in the first, 13 or 61.90 per cent.; in the second, 2 or 11.11 per cent.; in the third none were apparently cured[1]—showing a total of 28.84 per cent. cures. Besides these it is shown that there are 11 cases, or 21.15 per cent, in whom the disease is arrested, that is, in whom all constitutional disturbance has disappeared for several months, but in whom the bacilli, cough and expectoration are still present. It may not be too much to hope that a number, and possibly most of the arrested cases will in time go to swell the list of the cures.

Similar favorable testimony concerning the non-specific treatment of consumption is also attested by other institutions of a like character, notably by that of Dr. Detweiler, of Falkenstein. In fact such institutions demonstrate that the successful treatment of pulmonary consumption is no longer to be disputed, and they show that no chronic medical disease is so amenable to treatment as pulmonary consumption.

A most interesting point in this question is the fact that there is a consensus of opinion as to the methods which bring about the best results in the treatment of this disease. The first is *an institution* in which the patients are under the immediate and direct supervision of intelligent physicians and nurses. In regard to these Brehmer in no uncertain tones says (*Therapie der Chronischen Lungenschwindsucht* 1887, p. 93), "Special institutions for the treatment of consumption give the greatest promise of cure." Dr. Trudean states (*Transactions of American Climatological Assoc.*, 1889, p. 168), "If anything is to be done for those who are both poor and consumptive, it cannot be done outside of an institution." Many other physicians who have had experience of this sort are equally emphatic in their opinion on this subject.

The second is *rest*, or at least a rigid control of the physical movements of patients. On this subject Brehmer says (*Mittheilungen aus Dr. Brehmer's Heilanstalt*, 1889, pp. 43 and 45.) "This much I can assert that all fatigue is an injury and a poison to the consumptive. * * * The healthy individual rests because he is tired, but the consumptive must rest so that he cannot become tired."

One of the important instructions in Dr. Trudeau's Sanitarium is, "When feverish, patients will do well to make as little exertion as possible. Fatique, when induced in persons still having active disease is sure to be followed by loss of appetite, fever, exhaustion, and even sweating." (Trans. *American Climatological Assoc.*, 1889, p. 174.)

Dr. Detweiler, in his report for 1886, states that every patient who is not confined to bed must repose in the open air on a reclining chair throughout the greater part of the day.

Dr. Volland, of Davos, who has had extensive experience in the high altitude treatment of consumption declares (*Die Behandlung der Lungen-schwindsucht im Hochgebirge*, p. 18) that rest in the open air is the first duty of the consumptive patient, and that, if he is able, he is allowed to sit out-of-doors, and if not, he is confined to bed in a well ventilated chamber.

This feeling to regard *rest* as such an important element in the successful management of consumption is not confined to these and other public institutions, but is also shared by private practitioners, and it is based on the sound pathological reason that consumption is not a local disease of the lungs, but one which implicates the whole constitution. A consumptive must be looked upon as one verging on physiological bankruptcy. His whole strength is already absorbed in the performance of the necessary functions of life, frequently carried on imperfectly. His digestion is weak, his bowels may be disordered, sleep is restless and disturbed there is a waste of tissue owing to the fever, and his muscular power is impaired to such a degree that a short walk or a small amount of physical exercise saps his strength, and may wholly disable him. Yet strange and paradoxical as it seems, weak as he is,

[1] By apparently cured is meant when the rational signs of the disease and the bacilli have been absent for at least three months. I think it is but reasonable to assume that such cases are cured.

he persists in the belief that exercise is the one thing needful for his restoration. This feeling is not confined to consumptives, but lives in behest of a strong public sentiment. It is builded on the knowledge that in health exercise gives strength. But what an enormous difference between the body in a normal state, and when suffering from a chronic wasting disease like consumption! The two conditions may be illustrated by comparing a business man who is threatened with insolvency with one whose credit is good. If the former pays out as much as he takes in, his finances will always be in a crippled state, and he will be in constant danger of going to the wall; but if he halts—that is, if he diminishes his expenses and maintains or increases his income—his capital will accumulate, and in time he will be able to compete with other capitalists. But the business man whose credit is unimpaired goes on and invests all his surplus capital—that is, he exercises his financial strength to the utmost limit of prudence—and thereby enhances and improves the integrity of the institution which he represents. So it is with the taking of exercises. If this is to be beneficial, a certain amount of strength must be possessed by the individual before he begins it, and by putting this strength to proper use it will grow and accumulate; but he who has no, or very little strength at the outset, must reduce his expenditures, or his waste, and enlarge his income, or else go into physiological bankruptcy. We must realize that with the consumptive, it is wholly a question of constitutional resistance; that when he is weak the disease is strong and advances; that when he is strong the disease is weak and recedes; and that the force which he expends in performing exercise deducts so much from his total vitality, and allows so much less for the body to cope against the disease, and to perform the essential functions of life.

Moreover, there is a perfect agreement in these institutions in regard to the great utility of supplying nutritious food in the most concentrated form; of reducing high temperature with antipyrin, phenacetin, and antifebrin; of checking the waste which is occasioned by cough, expectoration, sweats, and diarrhœa; of employing pneumatic and climatic treatment; and in fact of everything which goes to enhance the vigor and vitality of the body.

I think I am justified in saying that hard, cold, positive facts are the best crucial tests to which a theory can be submitted in order to ascertain its correctness. The specific cure for consumption is utterly condemned, when compared with the general treatment of this disease on such a basis. How would mercury rank as a specific in syphilis, or quinine in ague, if their curative results were as hapless as those of tuberculin? Even if a specific cure for consumption were possible, it is difficult to see its need in view of the large number of cures, as I have shown, are annually made by other means. From my own personal experience, I can testify that there is no chronic disease which responds more readily and more promptly to persistent and well directed general treatment than pulmonary consumption; and there is no reason to doubt that with the advance of the scientific study of the disease the percentage of cures will increase. A specific cure for consumption is not of so much consideration now as a study and a development of the lines of treatment which have been shown to hold out such a magnificent measure of enduring success.

One more thought and I am done. Ever since the failure of tuberculin became generally palpable, there arose a feeling in the minds of many of his followers, that Dr. Koch had made a serious mistake in the practical application of his theory, and that eventually great therapeutic results are bound to flow from it. Dr. Koch is not in error, but is more consistent than many of his disciples who follow him in the distance. He has a logical belief in his theory, and knows what the practical application of tuberculin implies better than any other living being. There cannot be the least question concerning his ability to cure by inoculation, the disease which he artificially induced in animals; and if consumption in man were caused through contagion or inoculation, or was of the same nature as the disease which he produced in animals, it would be perfectly reasonable to hope that he could cure the consumption in the human family. But the disparity which exists between that which *is* and that which *seems*, is a vortex which has stranded and annihilated many an idea. This is not the first time that the contagion theory of consumption has come to grief. A century ago the government of Naples concluded that consumption was an infectious disease, and practised the most rigorous isolation of those who suffered from this disease, for more than fifty years. The results were abominable. Reliable historians inform us that besides causing untold misery, these laws were not

of the slightest service in diminishing the death rate from this disease.

Should we not profit by these dearly bought experiences? Is it not high time that we take an account of our bearings and begin to recognize that he who hugs the delusion that consumption will be cured or prevented through the miraculous operation of some anti-bacillary agent or process, will only live to reap "from the hopes which around him he sows, a harvest of barren regrets?"

THE ELECTRICAL TREATMENT OF FIBROID TUMORS—WITH AN ANALYSIS OF FORTY-SIX CASES. *

BY G. BETTON MASSEY, M D.,

PHILADELPHIA.

The progress of the Apostoli method of treating fibroid tumors of the uterus presents both analogies and contrasts to those of some of the recent theapeutic claims that have been widely investigated by the medical world. Recognized at last owing to the persistent agitation of its originator, it was, like the Brown-Séquard and Koch remedies, enthusiastically adopted by those pioneer advocates who often make up for crudeness of training and inexactness of observation by a debt of stimulated progress laid upon subsequent workers. In contrast to the theories alluded to, it has since borne the test of capable experiment to an extent that even exceeds the original claims, and with the broadened use of electricity in other allied conditions, has made a new departure in gynæcology. Unlike them, also, it has encountered an opposition of unparallelled fierceness, an opposition, nevertheless, that has been as healthy as it has been fierce. The cause of this unusual attitude towards a new remedy is easily seen in the recent extension of abdominal surgery, and this highl favored disease has heretofore been treated to a rivalry of methods that cannot be other than productive of the best results. Far from regretting this rivalry, I indeed point to it as an important index of medical development, and cannot but regret that other therapeutic efforts now blindly accepted are not subjected to similar tests. I do regret the intemperate statements of certain extreme opponents. Undermined in their wholesale and indiscriminate resort to dangerous operations by the attention bestowed upon a milder and non-dangerous method of enforced atrophy, they have been invariably the aggressors in controversy, condemning in unmeasured terms a method of which they knew nothing. This is in striking contrast to the position of electro-therapeutists, who willingly concede to surgery certain cases unsuited to electrical treatment yet demanding active help.

Experience is alone the final arbiter, and in view of the many cases of symptomatic cure and reduction, and the considerable number of those who that have disappeared under electrical treatment, now on record, it is in order for those who advocate an exclusively surgical treatment to come forward, not with wet specimens just removed from patients who may die subsequently, nor even mere reports of recoveries and deaths from the operations, but with full reports of the ultimate results in each case that withstood the operation of oophorectomy and hysterectomy. The profession is not simply interested in the average mortality of these operations for comparatively benign tumors, but wishes to know also the results in the restoration of health and comfort to these patients. For instance, some careful operator should tell us how often removal of the appendages for bleeding myomas fail to control the hæmorrhages; how often this procedure in patients approaching the menopause is followed by mental disturbance; how often a successful hysterectomy is followed by abdominal fistulas, intestinal adhesions, hernias and other sequelæ that are as troublesome and painful to the patient as the benign tumor itself had been. Until such statistics are collected there can be no true comparison of surgical and electrical methods, as the latter refer only to results that are always more or less remote from the remedial procedures.

As an illustration of the results of electrical treatment of these growths I have analysed the histories of forty-six cases treated consecutively by myself, in which I have considered the conditions present at the beginning of treatment, the nature of the treatment, and the results as ascertained at various periods after the cessation of treatment.

A study of these cases will show that seven cases should be eliminated from consideration in this paper because two were polypoid and their delivery per vaginam was merely assisted by the electrical applications made, and five were treated for so short a time or were so soon lost sight of that it is impossible to use them in demonstration.

This leaves thirty-nine cases that had more or less thorough treatment and in which the results have been ascertainable. These are

* Read in the Obstetrical Section, American Med. Assoc., May 7, 1891.

divisible into five classes in the matter of results attained:

Class I. Cases of complete anatomical and symptomatic cure, the tumors disappearing and the patient being restored to health. Of this class there were five cases.

Class II. Cases in which the tumor was considerably diminished in size and all other symptoms were cured. Of this class there were twenty-three.

Class III. Cases in which the tumor was not diminished in size but all the symptoms were relieved, or in which the tumor was reduced but the symptoms were not relieved. Of this class there were eight.

Class IV. Cases in which the tumors were not diminished nor the symptoms relieved. Of this class there were two.

Class V. Cases made worse by the treatment. Of this class there was but one.

PERCENTAGES.

Based upon the thirty-nine cases of thorough treatment, therefore, it will be seen that 12.8 per cent. resulted in a complete cure and disappearance of tumor; 79.4 per cent. in symptomatic cure with or without reduction in size; 5.3 per cent. were unaffected; and 2.5 per cent. were made worse. Omitting the case that was made worse since it was fibro-cystic and should not have been treated, the successes amount to 95 per cent. and the failures to five.

The prevalence of the several varieties of tumor in the series is shown in the following table:

	Intra-mural.	Intra-mural. and sub-peritoneal.	Subperitoneal.	Submucous
I. Complete disappearance	5			
II. Symptomatic cure and reduction.	15	3	4	1
III. Symptomatic relief without reduction.	6	1		1
IV. Unaffected by treatment.			2	
V. Made worse.				1

THE FAILURES.

Of the two cases unaffected by the treatment, one was that of a patient who had two painless, movable, subperitoneal growths attached to the uterus by long pedicles. There was absolutely no symptom whatever of these tumors, beyond the mere fact of their physical presence, and as they were not situated favorably for electro-puncture and were giving no trouble anyway they were left alone, after a thorough trial of mild intra-uterine applications. No. 33 was a large, kidney-shaped subperitoneal tumor attached to the anterior surface of the uterus and lying between the latter organ and the bladder. As the bladder was spread out in front of it, preventing puncture, resort was had to long continued vaginal galvanic alternatives. Under these the tumor was released from the pelvis, but the patient was not sure that she felt any better.

The case made worse was No. 3, a large intra-uterine fibrocyst which was treated before it was pointed out by Apostoli that this form was liable to be made worse by electricity. The death from septicæmia did not occur until sometime after the cessation of treatment and during attempts to extract the mass surgically by piece meal. The case resembled closely the one described by Emmett at page 587, of his work on the Diseases of Women, in which it is stated that death also occurred during attempts at extraction. Though sent to me by an expert surgeon my own case would have been far better treated by hysterectomy than by any form of electricity.

METHODS.

It will be noticed that six cases were treated by puncture. The greater number of these punctures were of the kind that has been designated as "buried"—a variety of puncture that was originated by myself, and one that I think more powerful and safer than that described by Apostoli. Unlike the Apostoli needle, which is only insulated by a movable sheath up to the point at which the puncture is made, my own needle is insulated by vulcanized rubber to within one centimeter of the end, with a view of preserving the track made by it through healthy tissue from an electrolytic softening that would prevent immediate union. Punctures made in this way have been proven by me to heal in three days in spite of the use of 150 ma. at the point within the fibroid tissue, while the older form of puncture usually remains unhealed for a week or more.

No unpleasant reactions followed any of the punctures, which were sometimes exceeding an inch in depth, and while I do not think that any but those skilled in it should attempt this method, I do not hesitate to employ it myself in those rare cases that are adapted to it. None of the cases in which the tumors disappeared were punctured, but this was merely because their intra-mural situation neither required nor permitted it.

The intra-uterine method is certainly the method of choice, and with gentleness, and especially the use when possible of the

elastic electrode devised by me, is free from risk in all cases except those complicated by acute inflammatory conditions. I have been disposed of late to increase the intervals between these applications to five or more days, interspersing one or more vagino-abdominal treatments for their contracting effect.

The vagino-abdominal galvanic alternatives that have been advocated by Danion of Paris have a considerable value when neither of the two better methods are available. I have seen reduction occur during the use of this method in several cases, and can testify to its power over inflammatory conditions in the pelvis.

As will be seen from the notes of some of the cases, persistent treatment has at times, been the keynote of success, though the best results were often attained in a short time.

Society Reports.

NEW YORK NEUROLOGICAL SOCIETY.

Meeting of May 5th, 1891.

The President, Dr. L. C. Gray, in the Chair.

The Back in Railway Spine.—Dr. F. X. Dercum, of Philadelphia, read a paper with this title. He said that it seemed to him in discussing railway injuries, the physical condition of the back had not been sufficiently dwelt upon. It was certain that more had been said pro and con upon injuries of the spinal contents, and far more still upon the subject of traumatic neuroses. It had been the speaker's fortune to examine a large number of railway and allied injuries, and it had appeared to him, that the condition of the back was often poorly understood and often unappreciated, while important points were sometimes entirely overlooked. Further conditions were occasionally observed which were difficult of explanation, and it was to these he wished to call attention. It was well known that pain of various kinds was met with in railway cases, but he wanted to exclude from the discussion all pains, the existence of which could not be confirmed by any physical evidence and which rested solely upon the unsupported statements of the patient. On the other hand all pain, signs of which were evoked without previous warning or suggestion should be rigidly admitted. He strongly advised the thorough examination of all such patients by superficial and deep pressure and by blows, as by this means information of decided character, might be gained in cases otherwise obscure. Another important method of test was by motion. In regard to pain elicited by voluntary motion, the objection might be urged that here an opportunity was presented to the malingerer. There were, however, so many other means of ascertaining the truth that difficulty in arriving at definite conclusions would rarely be experienced. Much depended upon the manner in which the various tests for motion were applied. These tests consisted of flexion forwards, lateral flexion, torsion and transmitted shock. Having first practiced palpation and pressure, and gleaned such information as could be obtained from these sources, with the patient standing before us the back should be closely inspected. Following this the tests for motion should be gone through. After having briefly considered the various tests for eliciting pain, he said that not only was it possible with due care to settle the question of the genuineness of the symptoms by any one of the methods detailed, but it was also evident that there must be a general correspondence in the results of all the methods. We should expect for instance that the area of pain upon deep pressure would correspond, other things being equal, to the area of pain on motion, or that the region of pain elicited by percussion would correspond to the region of pain elicited by transmitted shock. The speaker then detailed the histories of six cases bearing upon the question. The various symptoms presented by these cases could be conveniently grouped as follows: first, those due to the physical condition of the back; secondly, the symptoms of functional derangements and asthenia; and, thirdly, those that presented psychic and hysterical symptoms. To the first group belonged: first, pain on deep pressure; secondly, pain on motion and transmitted shock; thirdly, muscular spasm and rigidity; fourthly, muscular weakness. Now the pain elicited by pressure, motion, or shock, was evidently the result of a deep seated injury, either to the ligaments of the spinal column, or to the muscles, probably to both. Practically, it was impossible to differentiate between the two, nor was it important to do so. To muscular spasm and rigidity were to be assigned the same value which was assigned to the muscular spasm observed in a sprained, dislocated or broken limb. The muscular weakness resulting occasionally in lordosis, was to be ascribed to the general weakness resulting from the shock, and also to the direct effect of the trauma upon the muscles themselves. To

the group of symptoms of functional derangements and asthenia, belonged the various symptoms of general weakness, both mental and physical, tremor, sweating, inability to properly expel or to retain the urine, etc. To the group of psychic and hysterical symptoms was relegated the hypochondriæ, the night horrors and the convulsions. One important problem, however, still presented itself, and that was why it was that some of these cases did not attain their maximum severity for days and weeks after the accident. It was thought exceedingly probable that there was a direct extension of inflammation from the original site of the trauma along the sheaths and tendons of the muscles. It was difficult to escape from this inference, inasmuch as there was a marked spread in the area of pain on deep pressure. Hand in hand with this, there was, beyond doubt, a radiation in the muscular spasm, a radiation too which might reach not only muscles immediately adjacent, but those even relatively remote, such as muscles of the abdomen or of the shoulder. As to the question of duration of the symptoms it was impossible to give a definite answer. It was a question of probability, and of degree, and therefore one in which legitimate differences of opinion might obtain; however, taking the cases the speaker had seen, it was evident that chronocity must be admitted as established beyond cavil. In regard to the disappearance of so-called "litigation symptoms" made so much of by Page and others, the speaker's observations had been that when a claim for damages had been settled, the mental condition improved very much. A man who perhaps was poor, was suddenly raised to a condition of relative wealth. No wonder that hypochondria often disappeared and was replaced by buoyancy and exhaltation, it would be strange indeed if it were otherwise. After a while, however, he had seen the old mental condition partly re-establish itself, while the physical condition had undergone no change save that which could be accounted for by the slow repair of time. Lastly, the cases which had been presented were selected because of the marked and pronounced condition of the back. He did not wish to create the impression that every case should present the back symptoms to an equal degree in order to be considered genuine. As a matter of fact, in a large number of instances of *bona fide* railway back, the symptoms were far less evident than is the cases detailed. Finally he repeated that careful application of the various tests for eliciting pain and spasm could not fail to evoke a reply if trauma be really present.

Dr. G. M. Hammond called attention to a train of similar symptoms to those described by Dr. Dercum to be found in a modified form among athletes. This was especially the case with those who practiced jumping and running. He had seen several instances in which the patients complained of pain in the back and deep seated pain on pressure, and on stooping forward. There would also be exaggerated reflexes. These symptoms would persist for months while the individual was practicing his exercises. In jumping the foot struck the ground in the take-off with considerable force. In running long distances the repeated jar from the foot striking the ground would be transmitted to the spinal cord. Indeed it was his opinion that the symptoms he had met with were due to long continued transmitted concussion to the cord. After examining a great number of athletes he had invariably found that the knee-jerk was exaggerated, particularly among those who ran and walked.

Dr. E. C. Spitzka referred to some practical features of the paper and particularly to the tests used to locate the sprain. Conclusions drawn from a large number of cases were contradictory and the matter to a certain extent still obscure. Lateral flexion and torsion and transmitted concussion were of the utmost value. Within a year the speaker had seen one case of almost fatal collapse from severe transmitted concussion. The spinal deformity was often very slight and escaped observation while producing serious nervous symptoms due to slow hypertrophic changes.

Dr. A. D. Rockwell said that concussion of all kinds might be immediately followed by complete paralysis. When he was surgeon in the United States Cavalry in the late war, one of the men was injured while his horse was jumping a ditch. There was complete paralysis at once, the man being carried for several days in an ambulance. Partial recovery gradually took place. The speaker saw the man again a short time ago learning that he had always been more or less of an invalid, suffering from pain in the spine on pressure, melancholia and neuralgic symptoms. This condition had been present ever since the time of the injury. As to the treatment of cases such as the author had described he thought that the

actual cautery when properly applied gave the best results. He had used it in the instance narrated with direct benefit.

Dr. Dercum thought the tendency was to look for some other cause for these symptoms, other than the right one. If the physician would examine the spinal columns more carefully in patients complaining of the symptoms he had described diagnostic points would usually be determined.

Selected Formulæ.

FORMULA FOR WHOOPING COUGH.

Talamon, in the *Méd. Moderne*, gives the following formula for whooping cough:

℞

Terpini hydrati	1.0-1.5 grammes
Antipyrini	1.0 gramme
Syr. aurant. cork	50.0 grammes
Aquæ Tiliæ	60.0 grammes

M. et. Sig. One-half to one teaspoonful frequently during the day, for a child from one to four years of age.

ANTI-DYSPEPTIC POWDER.

Dujardin-Beaumetz, in the *Union Méd.*, gives the following formula, which he calls an "anti-dyspeptic" powder:

℞

Magn. sulph.	
Cret. præpar.	
Calc. phosphor. aa	10.0 grammes

M. et. div. in chart No. xl.
Sig. One powder before meals.

NITRATE OF SILVER IN CATARRHAL ICTERUS.

Dr. Niecechi, in *Medicina*, claims that nitrate of silver is specific in catarrhal icterus, checking all symptoms immediately. He gives the following formula:

℞

Arg. nitr.	0.06 gramme
Aquæ dest.	180.00 grammes

Sig. One tablespoonful three or four times a day. The dose may be repeated if not efficaceous. A rigorous anti-catarrhal diet should be enforced.

SUMMER DIARRHŒA.

℞

Resorcin	gr. iss.—gr. iij
Infus. chamomil.	ounces ij
Tr. opii	gtt. ij
Tr. cascarill.	gtt. xv

M. Sig. Teaspoonful every two hours.

—*Kinder-Arzt.*

PILLS FOR DYSENTERY.

The following pills used in the treatment of dysentery have given satisfactory results:

℞

Powdered ipecac.	gr. iv
Calomel.	gr. jss
Extract of opium.	gr. j

Make into three pills, and give one each hour, in the treatment of diarrhœa or dysentery due to exposure to heat.

—*Medical News.*

APHRODISIAC PILLS.

According to the *Journal de Médecine de Paris*, Lutaud employs the following for the purpose of producing sexual stimulation:

℞

Powdered nux vomica	¾ grain
Bromide of iron	15 grains
Phosphorus	⅙ grain
Excipient a sufficient quantity.	

Make into twenty pills and take one each night.

In addition to this treatment the patient should resort to hot and cold douches and gymnastic exercise, massage, and systemic tonics, and frequently coca will be found of value, as in the opinion of Lutaud this drug possesses very distinct aphrodisiac powers.

SALICYLATE OF MERCURY.

This remedy is one which has been largely neglected, despite the fact that it is useful to a high degree. One of the great drawbacks which attended its use was the impossibility of dissolving it in water without the addition of alcohol or of chloride of sodium. Otherwise this salt has antiseptic powers equal to corrosive sublimate, and is devoid of the latter's bad qualities. M. Vacher has overcome the difficulty of making a solution (*Medicine Moderne*) by obtaining salicylate of mercury through the double decomposition of a mixture of corrosive sublimate and salicylate of soda in water. In addition to the salicylate of mercury, a chloride of sodium is formed which makes the solution a stable one. This solution is not irritating, contains no alcohol, and may be used for various purposes according to its strength.

For external use the following formula may be employed:

℞

Hydrarg. bichlorid.	gr. iv
Sodii salicylat.	gr. viij
Aquæ.	oz. viij M.

If a weaker solution is desired, the following way be ordered:

℞

Hydrarg. bichlorid.	gr. j
Sodii salicylat.	gr. ij
Aquæ.	oz. x M.

For hypodermic injections in the treatment of syphilis, M. Vacher injects one cubic centimeter of the following solution, which has given him the best results:

℞

Hydrarg. bichlorid.	gr. v
Sodii salicylat.	gr. x
Aquæ destillat.	oz. j M.

One cubic centimeter contains three-twentieths of a grain of salicylate of mercury. The injection is not painful, and is never followed by abscess. Internally, a table-

spoonful, or slightly more, of a one to a thousand solution may be administered.—*St. Louis Med. and Surg. Journal.*

OINTMENT FOR ECZEMA.

℞

Thymol.....½ to 30 grains
Oxide of zinc, } of each.....6 drachms
Starch, }
Lard.....1½ ounce

Apply twice a day to the affected part.

—*Journ. de Méd. de Paris.*

WHOOPING COUGH.

For use at time of the paroxysm, Wilde recommends the following mixture, a teaspoonful of which is to be poured upon a compress and cautiously held near the child's mouth:

℞

Chloroformi.....f ʒ j
Æther. sulphuric. purif.....f. ʒ ij
Ess. terebinthinæ rect.....f. ʒ. iiss

—*M' Union Médicale.*

FOR EXTERNAL HÆMORRHOIDS.

Washing them with a solution of corrosive sublimate the strength of 1 to 1,000 or of carbolic acid, 1 to 50. After this the following salve may be applied:

℞

Iodoform.....grs. v
Extract of belladonna.....grs. viij
Vaseline..... ʒ j

SUBINVOLUTION OF THE UTERUS.

Professor Barton Cook Hirst, of the University of Pennsylvania, recently gave the following as the best combination to use:

℞

Strychninæ sulphatis.....gr. 1-20
Quininæ sulphatis.....gr. ij
Extract ergotæ.....gr. j

M. ft. pil. No. 1.
Sig.—At one dose. To be repeated thrice daily.

UTERINE WAFERS.

℞

Hydrarg bichlor.....gr. 1-16
Sulphate zinc.....grs. v
Sub nit. bismuth.....grs. xv
Pulv. gum arabic.....grs. v
Carbolic acid.....grs. iij

M. Pulverize the zinc; then add the rest of the ingredients, with q. s. water to make into a conical shape for a vaginal suppository.

This formula is offered to the profession as practically duplicating the Micajah medicated wafers. This formula, with the exception of the bismuth and acacia, has been used by the medical profession for a long time for onychia, etc. U. S. Dispensatory, 12th edition, Wood & Bache, page 1,115; used by Drs. Perkins and Physick.

TREATMENT OF BALANITIS.

Dr. W. R. Chichester states that he has obtained good results from the employment of the following (*Med. Rec.*):

℞

Atropiæ sulphatis.....gr. i
Zinci sulphatis.....gr. ij
Acid. boracic.....gr. v
Aquæ destillat..... ʒ j

M. Sig. Ayply two or three times a day with a brush.

He further states that this is open to any modification which the case suggests.

OX-GALL.

The following prescriptions containing ox-gall are recommended:

℞

Fellis bovis purificati,
Magnesii carbonatis, aa c.
Ol. menth. pip., *mj.*

M. et ft. capsulæ No, xx. Sig., a pill three or four times a day, after meals. Use in dyspepsia and constipation.

℞

Fellis bovis purificati..... ʒj
Ext. nucis vomicæ..... gr. j
Aloini..... gr. j
Ol. cinnamomi..... *mj*

M. et ft. pil. No. xx. Sig., two pills between meals. Serviceable in torpor of the liver and in dyspepsia.

—*Med. Rec.*

INFANTILE CONVULSIONS.

℞

Choral hydratis.....gr. iv
Potassii bromidi.....gr. viij
Aquæ.....
Syrupi.....aa.....dr. j

M. Sig. One dose for a child æt. two.

—*Jacobi.*

℞

Pepsinæ.....gr. xii to xxiv
Hydrarg. chlor. mit.....gr. ss to j
Sacch. lactis.....q. s.

M. et ft. chart. No. xii.
Sig. One powder every three hours after nursing.

℞

Ex. Pancreatis.....ʒss to j
Hydrarg. chlor. mit.....gr. ss. to j
Sacch. lactis.....q. s.

M. et. ft. chart. No. xii.
Sig. One powder every three hours immediately before or after nursing.

—*Annals Gynæcology and Pædiatrics.*

TREATMENT OF WHOOPING COUGH.

Löffler recommends the following solution to be used in the treatment of whooping cough:

℞

Freshly prepared chloride of silver.....1½ grain
Water.....2 pints
Hyposulphite of Sodium, a saturated solution.

Use by an atomizer, the liquid being directed into the pharynx. Repeat the application every two or three hours. This treatment is both prophylactic and curative.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

INTRA-UTERINE STEM PESSARY.

During the past few years, very little has appeared in current literature concerning the intra-uterine stem pessary, and it is evident that its use is being more and more restricted. Not many years ago the stem pessary was regarded as an indispensable instrument in the treatment of certain forms of flexions and versions of the uterus. Now, it is equally true that to most of the present generation the instrument is known only by having seen a cut of it in a text-book. Introduced and abandoned by Velpeau, reintroduced and abandoned by Amusat, it was forced upon the notice of the profession by Simpson, in 1848. For twenty years it was lauded or condemned by gynecologists of prominence, but gradually experience in its use, and new discoveries in pathology have limited its field of application and demonstrated the dangers arising from its employment. Views upon the pathology of flexions have undergone a revolution, and the conscensus of opinion to-day excludes the stem pessary in the treatment of flexions and versions.

In the treatment of atrophy of the uterus, and of the so-called infantile, or poorly developed uterus, with or without flexion, the use of the stem pessary, in connection with dilitation of the cervix, has its advocates. The stem pessary is advised also, especially by Wylie, to keep the cervix patulus after dilatation, and for the purpose of drainage. But inasmuch as the necessity for this procedure is felt only by a decided minority of operators, it may be assumed with safety that its omission would be a small loss.

Practically the stem pessary is used to-day for the treatment of the so-called infantile uterus, and of super-involution of the uterus —a very restricted field. The prognosis of super-involution of the uterus is notoriously bad; and when improvement does take place, it is usually but temporary. It is an open question as to whether super-involution of

the uterus is not equivalent to an early menopause. The infantile uterus is the result, as a rule, of a partial development of the sexual organs, and accompanies small ovaries—not infrequently cystic or cirrhotic—and small tubes. Menstruation in such cases is absent or imperfect. The reason why treatment directed to the uterus in such cases yield poor results is not far to seek. When, fortunately, the partial development is confined to the cervix or even to the uterus, and the tubes and ovaries are more perfectly developed, the prognosis is better. But in this field the stem pessary comes in competition with dilitation of the cervix, the use of electricity, and roborant medication combined with judicious exercise. It seems probable that the intra-uterine stem will continue to be used in certain cases of imperfect development of the sexual organs, not so much because of the positive good which its use will accomplish, but because this condition, when marked, is very rebellious to all treatment, and such unfortunate patients, especially when desirous of marriage, will demand that everything offering a reasonable hope of benefit shall be employed. But the practioner must remember the teachings of the past, and warn his patient of the danger of salpingitis and peritonitis from the use of the stem; and be prepared at any time to see the poor prospect for sexual develpment, previously possessed by his patient, absolutely destroyed by the occurrence of serious pelvic inflammation.

Correspondence.

Our Inadequate Hospital Facilities for the Management of Mild Cases of Contageous Diseases.

To the Editor of the Medical and Surgical Reporter.

Dear Sir:—I desire to relate a recent experience, not with the intention of fault-finding, but rather with the hope that benefit may result from its consideration.

On Thursday, May 14, I was called to see a servant girl, Kate M., who, I was informed had been ailing since the previous Tuesday evening. Upon examination I found her to be suffering from a well-marked follicular tonsillitis, this being the eighth case of the kind I had seen in our square during the week. As she did not properly carry out the measures I suggested, and was rather troublesome to wait upon, the family, by whom she was employed, desired her removal. I accordingly arranged to have her admitted to the Philadelphia Hospital, as she said she could not afford to pay board anywhere.

Just as she was about to start for the Hospital, however, I detected for the first time, a profuse rash over her neck, breast, arms, legs and slightly on her face. There was no exacerbation of general symptoms, and my knowledge of her condition for the previous two days enabled me to conclude promptly that the eruption was not due to scarlet fever but to Rötheln. I so pronounced it, and had her conveyed, in the carriage hired by her friends, to the Philadelphia Hospital.

Upon arriving there she was refused admittance because of the contagious nature of her disease. Not having any place to go she had the driver bring her to my office for advice. Thinking it probable that a mistake in diagnosis had been made and scarlet fever suspected from the combination of sore throat and a rash, which certainly resembles the eruption of scarlet fever at times, I decided to accompany the girl to the Hospital, to make explanation, and accordingly had her taken there for the second time. Unfortunately the Hospital officials informed me that they could not receive a case of Rötheln and that the proper place for such a patient was the Municipal Hospital. We then proceeded to that institution where she was received and placed in a vacant ward, as I was particularly anxious that she should not contract a trouble more serious in nature than the one she had upon entering. After the arrival of the physician of the institution, after my departure, the case was diagnosticated as scarlet fever, and she was placed in a ward with some patients who were convalescing from that disease. These facts I learned upon visiting her on Monday morning, about 36 hours after her admission to the Hospital. Examining her at this time I found her throat decidedly improved, no secretion in the follicles of the tonsils and the inflammatory action greatly subdued. The rash had disappeared. Temperature was 98° F., having rapidly come down from 102° F., which

was the record upon admission, and which I am quite sure was largely due to nervousness, as her temperature had been normal that morning.

So much was I impressed with the correctness of my original diagnosis, and so greatly did I feel the dangers she incurred from contact with her contagious surroundings, that I called upon the physician in charge of the Hospital and asked if she could not be removed to safer quarters. I was informed that even granting a mistake had been made by him in the diagnosis of the case it was not possible to do any better for the girl than keep her where she had been placed, that they did not have any room where cases of such mild contagion could be separately cared for, and that the nurse who would be obliged to wait upon her, had charge of cases of scarlet fever and diptheria; and finally that as long as she had been for over 24 hours in the scarlet fever ward, she would not be apt to escape that disease by removal from the ward.

Whether this particular case is one of Rötheln or of scarlet fever matters little as far as my purpose in this communication is concerned. While freely admitting my liability to err in diagnosis, I, however, feel justified in holding my original opinion respecting the nature of this girl's illness, and I also greatly fear that she will be the victim of a much more serious malady, due to her incarceration in a room poisoned by scarlet fever patients. Several questions have presented themselves as a result of this experience:

1st. Is it just to Philadelphia citizens that the city's Hospital for contagious diseases should have no ward or wards set apart for the reception of contagious diseases of such a mild character as Rötheln, when patients may be cared for by nurses not on duty amongst cases of a more serious character?

2nd. Is it just to the physicians who may be obliged to do as I did and allow their patients to run the risk of contracting a more serious affection in the place they are confined for safety?

3d. Might not a physican be caused much annoyance if a patient felt disposed to prosecute him in case a more serious disease were contracted while at the Hospital?

It would seem that the claims of economy would demand better facilities for the management of the mild contagious diseases at the municipal Hospital, when we consider the relatively greater period of time patients must be boarded when afflicted with a grave disease. Certain it is that the claims of humanity demand such attention.

Respectfully,

Wm. A. Carey,
1947 North 18th Street.

Ed. Medical and Surgical Reporter.

Dear Sir:—Will you or some of your readers please give through the columns of your valuable journal, a remedy, or remedies to allay the itching following the hypodermic use of morphia, and oblige. Yours,

R. C. Spear, M. D.,
Mt. Gilead, O.

Ed. Medical and Surgical Reporter.

Dear Sir:—Speaking of Hydrogen Peroxide; I used it recently to wash out a foul suppurating abscess in the roof of the vagina, after previously cleansing it with a bichloride solution. The abscess held about half a teacupful of pus, and had been existent for twenty years. Result was complete cure after one application.

Wm. H. Burr, M. D.,
Wilmington, Del.

Book Reviews.

BLAKISTON'S QUIZ COMPENDS. A COMPEND OF DISEASES OF CHILDREN, ESPECIALLY ADAPTED FOR THE USE OF MEDICAL STUDENTS. By Marcus P. Hatfeild, A. M., M. D., Professor of Diseases of Children, Chicago Med. College, etc. One colored plate. Phila., 1890.

This epitome of the diseases of children consists of the condensed annual course of lectures delivered at the Chicago Medical College by the author. The lectures in turn, the author states in his preface, were founded upon Dr. Ernst Kormann's "Compendium der Kinderkrankheiten," which was translated by him in coöperation with Dr. E. J. Doering, at the University of Berlin. The frontispiece consists of a very good colored diagramatic sketch of the fœtal circulation, which is a wise provision in a book intended "especially for the use of medical students." We believe the book is admirably suited to the requirements of students, being clearly written, and consisting chiefly of definitions and short explanatory passages. This arrangement enables the small size so valuable in a quiz-compend, while allowing the work to embrace all of the chief affections of childhood. It is an excellent synopsis of the diseases of children and as such we commend it to the students for whom it is intended.

ORIGIN, PURPOSE AND DESTINY OF MAN OR PHILOSOPHY OF THE THREE ETHERS. By William Thornton. Boston. Published by the author, 1891.

In this little book of one hundred pages, the author continues the thoughts expressed in his "Rationalism in Medicine" published in 1885. This philosophical essay will not be of any use to the busy practitioner of modern medicine, since one of the conclusions reached, is, that all drugs now commonly administered are positively harmful to the organism, since according to the theory advanced by the writer, nothing should be given in disease except those substances which are normally found in the body. To those who are interested in philosophy, especially as it bears upon the science of medicine, this volume will be found worth a careful reading, particularly the chapters devoted to the "philosophy of the three ethers" and "how to make medicine a science." In fact the whole essay is written in graceful language, and the theories of which the author treats and applies to medical science, are extremely enticing. The writer also devotes a chapter to the subject of the immortality of the *Life*, which his philosophy separates from its "material environment." To thoroughly appreciate the *idea* of the book, it must be carefully perused, since space will not here permit even a clear synopsis of thought advanced.

KOCH'S METHOD TO CURE TUBERCULOSIS, POPULARLY TREATED BY DR. MAX BIRNBAUM. Translated from the German by Dr. Fr. Brendecke. Milwaukee, Haferkorn, 1891, pp. 95.

This brochure consists for the greater part of a popular résumé of our knowledge of the tubercular process in its various manifestations; its consideration of Koch's method of treatment is limited to the republication of Koch's first communication in the medical papers. There is little in the pamphlet that is not much better treated elsewhere; and the success of the translation is extremely doubtful from an English point of view, the failure to dispose of the many Germanisms rendering the text rather unpleasant to readers unaccustomed to such idioms.

Considered as a medical work it is worthless because of the unsoundness of many of its statements and the brevity of the consideration of important points. As a popular presentation of tuberculosis, it is about what might be expected from a writer who confounds lupus with ring-worm, as is repeatedly done in its pages. As a review of Koch's work in the treatment of the tubercular process, there is everything to desire, little or nothing to be found, as the pamphlet was published before Prof. Koch had announced the character of the matter he employs and its manner of manufacture.

PERISCOPE.

THERAPEUTICS.

THE THERAPEUTIC VALUE OF CETRARIN.

Cetrarin is the name which has been given to the active principle of Iceland Moss. The drug is one having several valuable therapeutic properties. Recent experiments show that it stimulates the stomach and also the intestinal peristalsis, it also increases the number of both red and white corpuscles in cases of anæmia, and, finally, acts as a tonic to the nervous system. Kobert, in the *Journal de Méd. de Paris*, April 19, 1891, states that he has found cetrarin of great value in cases of chloranæmia complicated with constipation and loss of appetite. The dose employed was 10 centigramme in any convenient vehicles.

SOZOIODOL.

The comparatively new antiseptic, Sozoiodol has already been brought to the notice of the readers of The Reporter some time ago. It will be remembered that its chemical name is bi-iodo-para-phenyl-sulphuric acid. It is obtained by the action of fuming sulphuric acid on bi-iodide of benzine, which is saturated with carbonate of lead and filtered. The lead salt is decomposed from the mixture by sulphuretted hydrogen, and the aqueous solution allowed to evaporate. The crystals which are then formed are those of Sozoidol. The preparation contains 42% of iodine.

Recent investigations have confirmed the valuable antiseptic properties of this drug. It is similar, yet in many ways far superior to iodoform. Its odor is not unpleasant, and its healing properties more marked. Its action in tuberculous or scrofulous ulcerations is excellent, and it has been used with success in both gonorrhœa and syphilitic sores of the generative organs. A rapid curative action has also been seen to follow its use in various chronic cutaneous affections, in ozena, and in laryngitis. As in antiseptic in surgery, it is very useful,

promoting rapid healing, and keeping the parts free from infection. It may be advantageously dispensed in connection with starch, vaseline, or cerate.—*Journal de Méd. de Paris*, April 19, 1891.

TREATMENT FOR VARICOSE LEG-ULCERS.

Basing his opinion upon numerous experiments and a large number of successful cases, Dr. J. Braun, in the *Allgemeine Med. Central-Zeitung*, May 6, 1891, advocates most highly the treatment of leg ulcers with the following formula:

℞ Zinci oxyd..... 15.0 grammes
Lanolini.....100.0 "
Unguent. moll..... 40.0 "
M.

The ulcer should first be carefully washed and dried and the above salve, thickly spread upon a piece of linen, applied, and covered with a light bandage. The patient should be kept in bed. Almost immediately after application of the ointment all pain and itching will disappear, and the copious discharge will soon lessen.

According to Braun this salve forms a protective covering over the ulcer, and the lanolin absorbs the purulent discharge, while further suppuration is checked. The ulcer will therefore become dry and heal. In discolored ulcers the salve should be applied four or five times a day. In about three or four days the ulcerated surface will assume a healthy appearance and cicatrization will begin. The author has even seen deep and extensive varicose ulcers heal in this way, without any transplantation of skin being necessary. After healing, the author advises that an elastic bandage should be worn for some time over the seat of the ulcer.

This same salve has been found by Braun to be of great service in eczema, and as an application to any granulating surface. In eczema capillittii the addition of a little bichloride of mercury will be found excellent.

BROMIDE OF ETHYLENE IN EPILEPSY.

The *Münchner Med. Wochenschrift*, May 5, 1891, contains the description of a new anti-epileptic, reported by Dr. J. Donath, of Budapest. The remedy advocated is bromide of ethylene (æthylenum bromatum). The drug is of a light brown color and smells something like chloroform. Its taste is sweet, but it leaves a burning sensation in the mouth. At O°C. it freezes to a snow-white crystalline mass, and it boils at 131° C. Its specific gravity is comparatively high, being 2.163, at 21°C. Bromide of ethylene contains 90.9 per cent. of bromine. The fluid is insoluble in water, but is soluble in any proportion of rectified alcohol, and forms a perfectly clear solution in any of the fatty oils, such as oil of sweet almonds.

The drug is best given in the following 5 per cent. oily emulsion:

℞ Aethyleni brom..... 5.0 grammes
Ad. emuls. oleos.....100.0 "
M. Sig.

Thirty drops in a little sugar and water two or three times a day for adults. On the third day the dose should be increased to 40 drops; in three days again to a coffee-spoonful, then to a teaspoonful. In children from eight to ten years of age, the initial dose should only be 10–20 drops. The dilution of the emulsion in water or milk is necessitated on account of its irritating properties, and any gastric irritation is to be avoided. In patients with extremely irritable stomachs, gramme 0, 1–0,2 of the aqueous extract of opium should be added to the above formula. Toxic symptoms following the use of the drug were never observed.

Another simple form for its administration is:

℞ Aethyleni brom. aromati.
Spirit vini rect.....aa.....5 0 grammes
M. Sig. 5, 10 to 15 drops well stirred in ⅓ glass of milk two or three times a day.

Very sensitive persons may take the drug in gelatine capsules, associated with almond oil; each capsule containing three drops of bromide of ethylene and six drops of almond oil. Two to four of these capsules to be taken daily.

Dr. Donath has used the drug in twenty-one cases of epilepsy, and reports fully the history of ten of these cases which were under observation for a long period. It was observed that under the remedy's influence the convulsions occurred more seldom, that they were of shorter duration, and milder. Frequently the disease becomes of a much milder type and the period of immunity from the convulsions increased. In some cases the improvement was so great, that the convulsions only amounted to slight muscular twitchings without loss of consciousness. The general condition of the patients was also greatly improved by the treatment. In many respects the drug's actions are far more favorable than those of bromide of potassium.

IODOFORM IN BURNS.

Rottenberg, in the *Münchener Med. Wochenschrift*, May 5, 1891, speaks of the great efficacy of iodoform in all kinds of burns, and especially those caused by molton iron. His method of treatment is as follows: Through the punctured blisters he pulls a silk thread soaked in a bichloride solution; he then covers the entire surface of the wound with a thick layer of the following salve:

℞ Iodoform.....10 parts
Vaseline.....100 "

This is then covered with rubber or a protective. The salve should be freshly applied daily.

This treatment not only results in a speedy cure, but also relieves almost like magic the burning pains.

THE TREATMENT OF PNEUMONIA BY LARGE DOSES OF DIGITALIS.

We have already on one or two occasions called attention to the mode of treatment recommended by Dr. Petresco of combating pneumonia with large doses of digitalis, and in the *Therapeutische Monatshefte* for February, 1891, this author publishes an additional communication on this subject, in which he offers a number of arguments and reports of a number of cases to support his position as to the value of very large doses of digitalis in this disease. The dose which this author recommends is simply enormous in contrast to that which is ordinarily regarded as the safe dose of digitalis, Professor Pretresco stating that he does not hesitate in single doses to give as much as 180 grains of digitalis-leaves in twenty-four hours, although he admits that ordinarily the dose for twenty-four hours does not exceed 25 grains. He prefers the infusion made with 4 parts of digitalis-leaves in 200 of water, and then adding 40 parts of syrup of orange-peel, the dose then being a tablespoonful every half hour. He states that in general this dose is very well borne, and that he has never met a single case of poisoning. Dr. Petresco meets the incredulity which has been expressed as to the tolerance of these large doses, with the explanation that he can only have employed inferior quality of digitalis-leaves, with a denial, and states that he has employed the leaves obtained from all the best pharmacists in Europe, with, as a rule, the same results. He states that he has obtained the best results in genuine fibrous or croupous pneumonia. In infectious pneumonia he has usually combined it with antiseptic methods. He also states that he has obtained satisfactory results in cases of pneumonia complicated with bronchitis and pleurisy, and he claims in the most positive manner to have cut short undoubted cases of croupous pneumonia, so that within twenty-four to forty-eight hours—the time necessary for the effects of the digitalis to be demonstrated—he has succeeded in obtaining sudden and almost absolute reduction of the temperature to the normal, accompanied with reduction of the pulse, while at the same time this disappearance of fever is accompanied by general improvement in the patient's condition, pain and cough being diminished, the temperature becoming normal, while the healing process rapidly goes on to completion. These large doses, with the exception of but rare cases, are without effect on the digestive canal, although sometimes he has met with vomiting as the result of this method of treatment. The most evident symptom detectable as to the effect of this medication is the marked slowing in the pulse, with increased tension. The author publishes a number of sphygmograms, illustrating the effect of digitalis on the pulse in cases of pneumonia, and concludes his paper with the following deductions:

1. Digitalis has an important antiphlogistic action only in its special therapeutic dose.

2. Its specific therapeutic dose of digitalis amounts to from 75 to 150 grains of digitalis-leaves administered as an infusion in twenty-four hours.

3. This dose may be administered in from two to four days continuously, according to the severity of the case. In some cases from 300 to 375 grains of digitalis-leaves being given in four or five days without symptoms of nausea, or in fact, any toxic effect. Treated with this dose, the temperature in cases of pneumonia falls from 1° to 3° C. after a single dose, and from 5° to 6° C. after three doses, while the pulse is slowed from 40 to 60 beats in the minute after six doses. This reduction in the pulse-frequency and in the temperature lasts from ten to twelve days, by which time the normal condition has been gradually obtained.

4. Simultaneously with this diminution in the rate of circulation and respiration, disappearance of all the local symptoms of pneumonia can be noted.

5. The value of this method of treatment is proved by statistics, the mortality of cases of pneumonia so treated with high doses of digitalis being much less than that observable when any other method is employed.

6. The value and harmlessness of this therapeutic dose of digitalis is established by the author's numerous individual experiments and by the cases reported by his scholars.

7. From studies as to the value of this method of treatment the author concludes that the expectant method of treating pneumonia is not only irrational but even dangerous; that the assumption that there is a definite cycle of progress in pneumonia is not warranted; that pneumonia may be cut short by an energetic rational mode of treatment, especially if the method is inaugurated at the onset of the disease, and that, finally, the claim is supported that the treatment of pneumonia with large doses of digitalis furnishes better results than that obtainable by any other mode of procedure.—*Ther. Gaz.*

THE TREATMENT OF RHEUMATIC HYPERPYREXIA.

Dr. Herbert C. Male, in the *Practitioner* says: The occurrence of hyperpyrexia in acute rheumatism, though happily rare, is a complication of grave import, and demands most active and immediate treatment.

Previous to 1870, cases of Cerebral Rheumatism with extreme pyrexia were mostly regarded as hopeless. In this year however Meding, published a case of rheumatic fever, in which a temperature of 108.6° was successfully reduced by means of cold affusion and iced enemata; and in the following year Wilson Fox further drew the attention of the profession to the subject by his treatise on *Hyperpyrexia*, and described very fully two cases of extreme pyrexia (temp. 107.3° and 110°), where the treatment by the external application of cold was carried out with success. Since that time the value of this method of treatment has been universally recognized.

It has been abundantly proved that excessive rises of temperature, in rheumatism at all events, cannot be kept in check by drugs alone. Quinine has been given in large doses, as much as 120 grains in six hours. In the case reported below, the patient was saturated with quinine; he had been taking 12 grs. *per diem* for a fortnight previously, and on the approach of hyperpyrexia large doses were given and continued without any apparent effect on the temperature. Salicylic acid and its salts are powerless, and the complication has often arisen in patients who have been throughout their illness treated by full doses of this drug. Antipyrin and antifebrin are transient in their effects, and are dangerous to continue from their depressing effect on the heart, which is probably already weakened by the disease. Antifebrin was given to the patient A. H. on November 4; the temperature did not rise during its administration, and it certainly had the effect of causing some moisture to appear on the skin which was previously harsh and dry. Delirium was not relieved. It was not thought advisable, in his weak condition, to continue its use.

Relying therefore solely on the employment of cold in reducing excess of temperature, we must decide at what temperature this treatment must be commenced. Wilson Fox has never seen a case of rheumatic fever recover unbathed after a temperature of 106° has been attained. Merchison has known a case recover after a temperature of 106.5°, but he states that this must be extremely rare.

In other diseases, such as typhoid fever and pneumonia, a temperature of 108° has been reached and recovered from, without special treatment, but Wilson Fox thinks that the "power of sustaining life in acute rheumatism after excessive temperature is less than in other diseases"; therefore we cannot afford to wait so long.

Some ten years ago the Committee of the Clinical Society of London made an exhaustive inquiry into this subject, and in their Report they show the necessity of not allowing the temperature to exceed 105°. In six out of eleven fatal cases (unbathed) the temperature did not reach 106°, and they have shown that the treatment by cold is more successful the earlier it is commenced. Moreover the temperature may rapidly rise when once it begins: in a case mentioned by Fox the temperature ran up from ordinary to 109° in two hours.

There are practically but two methods of applying cold to the surface of the body with the view of reducing temperature; by means of the *bath*, and by the *cold pack*.

When the *bath* is used, it is recommended that the patient be lowered into it in a sheet, at a temperature of 90°—100° F., and that it be cooled down by adding cold water, or preferably pieces of ice, till it is reduced to 60° or 70°.

He should remain in the bath till the thermometer, placed in the rectum, has fallen to 101°—102°, unless any symptom of faintness or shivering require it to be discontinued earlier. In many cases the patient's temperature continues to fall after his removal from the bath. He must be

rubbed dry, and placed in bed lightly covered with blankets; if the temperature fall too low, or the patient is shivering, hot bottles and stimulants are required.

The *cold pack* is best applied in the following way:—The patient remains in his bed; he is stripped of all clothing and a mackintosh is placed under him. Towels are wrung out of iced water and applied to the trunk, head, and limbs. These are changed frequently, and the body sponged over with lumps of ice. An ice-bag should also be applied along the whole length of the spine. The temperature must be carefully watched as before, and the pack discontinued when its reduction has been effected.

The *choice of method* to be employed must depend on the circumstances of the case.

In hospital practice where sufficient assistance and all appliances are at hand, the bath is generally preferred. It is doubtless a more thorough method, and appears to be attended by no greater shock or risk to the patient. On the other hand in private practice it is seldom that the bath can be satisfactorily employed, and for several reasons the pack may be preferred. It can be applied at once, it is less alarming to the friends, it does not necessitate the moving about of the patient, it can be carried out by one intelligent attendant without constant medical supervision, and its effect on the patient can be more readily watched. Moreover it has been proved to be thoroughly successful even in extreme cases of hyperpyrexia. Temperatures above 110° F. have been recovered from after treatment by the cold pack, as well as by the bath.

In some cases one bathing is sufficient to effect reduction of temperature, no further excessive rise taking place. In others it has required to be repeated, and it has been used as often as twenty-six times on the same patient with ultimate success.

The length of time required for reduction varies considerably, and bears no proportion to the severity of the case. In the case reported, the time that the pack required to be used varied from half-an-hour to three hours.

The following facts will give some idea of the proportion of recoveries that may be looked for after this treatment.

Wilson Fox collected a series of twenty-two cases from 1867 to 1871, temperatures ranging between 106° and 111.7°; eighteen were treated by ordinary means without the application of cold, and all were fatal; the remaining four were treated by the cold bath and three of them were successful, the highest temperature being 110°.

The Committee of the Clinical Society of London collected a series of sixty-seven cases during the ten years ending 1879. In thirty-nine of these the temperature exceeded 106°, and in thirty-four the treatment by cold bathing was adopted, and fourteen recovered, the highest temperature being 109°—110°.

Of the more moderate temperatures among these (viz. between 106° and 107°), eight out of eleven cases recovered, over two-thirds. All the cases that were unbathed died.

In the ten years ending 1890 many cases of recovery have been reported from time to time in the journals, and I have been able to find a record of sixteen cases with thirteen recoveries; temperatures ranging from 106° —110.4°. The pack was used in eight of these with two deaths, and the bath in the remaining eight with one death.

It is not possible of course to form an accurate idea of the proportion of recoveries from the study of published cases alone, as it is probable that many unsuccessful ones have not been published, while the majority of successful cases have been put on record. Still there is ample evidence of frequent recovery after extreme temperatures, which under other conditions must certainly have been fatal.

While however recognizing the success that often follows the employment of cold in rheumatic pyrexia, we must ascertain if there are any dangers attending its use.

Bristowe, records a case where the cold bath on two occasions produced such serious faintness, after five minutes' immersion, that it had to be discontinued.

At Guy's Hospital,[2] during 1874 and 1877, death took place on two occasions during immersion; but in these cases the bath was probably too long delayed, and the heart and tissues had suffered too much from the excessive heat to stand the shock.

In several cases violent purgation has resulted after immersion.

In a case previously reported by the writer, tetaniform convulsions, which occurred after the first application of cold, were so exaggerated on the attempted repetition of the pack, that it was impossible to apply it. The patient eventually died asphyxiated during a convulsive spasm. Another case of a similar kind has also been recorded.

These difficulties, however, appear to be exceptional, and it is well to note that the

various visceral lesions, such as pericarditis and pneumonia, so common in acute rheumatism, are no contra-indications to the use of cold. Indeed, as Wilson Fox asserts, intense pyrexia predisposes to congestion of internal organs, and the physical signs of such have been frequently observed to clear up during treatment by cold.

The following case is recorded, not unfortunately, as an example of a cure after cold packing, but to show the marked effect of this treatment in keeping the temperature within bounds over a prolonged period, its reduction being effected on each of the eight occasions on which it was used. It further shows that, on the discontinuance of the treatment, there followed a rapid rise of temperature, with exaggeration of all the symptoms until the fatal termination. The case also illustrates the variability of the time required to effect a reduction of temperature.

The spinal ice-bag was chiefly of service when used in conjunction with the iced towels. When employed alone, it appeared on the first occasion to delay for several hours a threatening rise, and the second time, when the bag was allowed to remain after the removal of the towels, the temperature continued to fall for three hours, and rose again slightly after it was removed. On another ocasion, the afternoon of November 5, the temperature rose rapidly in spite of it.

There was little doubt the patient's life was lengthened for some days by the treatment. It prolonged a period when the efforts of nature might have brought about a change for the better, had other conditions been favorable.

Previous to the onset of hyperpyrexia, the patient's strength was already exhausted. He had been ill for over five weeks, with constant pain and want of sleep. Pericarditis had existed long enough to cause such local organic change as seriously hampered the action of his heart, and this further lessened his chances of recovery.

Such a case impresses upon us the necessity of making a most careful record of temperature in all cases of acute rheumatism, and of recognizing at once the earliest signs of approaching hyperpyrexia.

Should the temperature show an undue rise, we should not waste valuable time by the administration of drugs, but endeavor to check it at once by the prompt application of cold.

The result of such treatment in a favorable case, is most gratifying. The patient may be dying from excess of temperature one hour, and the next may be in comparitive comfort, and with prospects of a speedy recovery. One bathing has frequently turned the scale. The treatment may be applied readily both in private and in hospital practice, and should not be withheld from any patient, in whatever circumstances he may be placed.

MEDICINE.

SALICYLATE OF MERCURY AS AN ANTISEPTIC.

At a recent meeting of the Surgical Society of Paris, Dr. Vacher, of Orléans, read a paper on the antiseptic qualities of salicylate of mercury, which is quoted in the *Bulletin Médical*. He considers the drug an admirable antiseptic, and superier to Van Swieten's solution because solutions of salicylate of mercury need not contain alcohol. Solutions of any strength are perfectly stable and will keep indefinitely. It is non-irritating and a powerful antiseptic. In the treatment of syphilis Dr. Vacher has found it to be of great service, particularly when given hypodermically. The injections produce no pain and cause no local inflammation. The author has used the drug in solution hypodermically in over one hundred cases of syphilis and with the best results. Salicylate of mercury is always well tolerated.

NOVEL TREATMENT OF GONORRHŒA.

Dr. Hanicka, in the *Reichs-Medicinal-Anzeiger*, May 15, 1891, speaks highly of the following novel treatment for gonorrhœa: A powder composed of equal parts of tannin, iodoform, and sulphate of thallin is applied to the urethra by means of a catheter-like instrument until the former is entirely full of the remedy. Prompt healing is said to take place in every instance.

NINETY CASES OF PARETIC DEMENTIA.

Dr. G. R. Trowbridge, in the *Alienist and Neurologist*, writes: The very fact that this disease was practically unrecognized in this country forty years ago, and to-day ranks among the worst forms of insanity, is sufficient reason to make statistics on the subject both of considerable interest and value. In all probability there were cases of paretic dementia before the time of Bayle, and although he is credited, I believe, with first having accurately described the signs

and symptoms of it about the year 1825, it is scarcely probable that the inhabitants of this world were exempt from it though it was not recognized and understood as it is to-day.

History is indirectly contradictory to this, and if we are to believe the facts as recorded there were certainly sufficient causes in the Middle Ages to produce a generous supply of paretic dementia, and I have not the least doubt but that it existed to a considerable extent among the so-called nobility of France, England and other European nations, whose ideas of morality and moderation were somewhat at a discount. The same causes which are producing it to-day were in working order then, though perhaps not to so great an extent; and granting that the mental, moral and physical conditions of two centuries ago were practically the same as those of the nineteenth century, it is fair to conclude that this age is not entirely responsible for this disease.

That paretic dementia is increasing in this country with alarming rapidity there is no room for doubt, as the reports of our institutions for the insane show. It is, however, only another indication of the "fast" age in which we live; and this yearly increase of the disorder is not a thing of which the American citizen should be proud, but on the contrary, it should be looked upon as a veritable curse, as it only proves that those vices and immoralities which are the cornerstone of general paresis, are increasing and causing the moral, physical and mental wreck of our fellow-citizens. No one can realize the truth of this better than the medical officers in our hospitals for the insane. In a large number of cases of paretic dementia admitted to hospitals for the insane, causes for the disease are given which are ridiculous in the extreme; and though either through ignorance or unwillingness on the part of friends, or delicacy on the part of the physician, the real and true cause cannot be ascertained, yet in three cases out of five it would be a comparatively easy matter to guess it, as the real causes of paretic dementia can be sifted down to an extremely small number.

The following statistics of ninety cases were compiled from the registers of this hospital, and though they are more or less defective, they present some interesting points.

Of the 3,518 admissions to this hospital, 90 were cases of paretic dementia; 77 of these being males and 13 females. This is about two and one-half per cent of the entire number admitted.

In the State Hospital for the Insane, at Independence, Iowa, of 3,700 admissions, 40, or a little over one per cent, were cases of paretic dementia.

Of 2,297 male patients at the Pauper Asylum of N. Y. City, 284, or a little over twelve per cent, were paretic.

First among exciting causes is the excessive use of alcohol. This is acknowledged, I believe, by the majority of writers to be a great producer of general paralysis. In close relation to it, both socially and as an exciting cause, is syphilis. It is claimed by some that syphilis is not an exciting cause of paretic dementia, but there are cases of general paralysis which cannot be traced to any other source, and the symptoms of this form are so identical with the regular general paralysis that it is stretching a point to claim another name for the disease. It is a distinction without a difference. This, however, does not mean that syphilis always produces paretic dementia to the exclusion of other insanities.

The excessive indulgence of vicious habits, as a rule, is likely to produce some impairment of the mental faculties, and in the majority of cases of paretic dementia, were the truth known, alcohol and syphilis would occupy the first place as exciting causes.

Here, again, the question reverts to one of social standing. Alcohol and syphilis are luxuries which are placed within the reach of everybody, from the laborer to the millionaire, but we find in my ninety cases, on a close comparison, that as the number in the exciting causes lessens, the cause itself becomes more respectable. I found that intemperance was given as a cause, especially among laborers and miners, and the same was true of syphilis, whereas the occupation, being a little better, the cause appeared as overwork, or was unknown.

Paretic dementia, as a rule, does not attack vigorous and well-balanced minds, unless, perchance, heredity plays a part, but is found among the class whose morals are of such a low grade that regard for themselves or others is completely destroyed, and they give themselves up to immoralities and vices which are the exciting causes of the disease. Thirty-four of the seventy-seven cases were due to either alcoholism, syphilis or heredity, or a combination of two or more, and I venture to say that in the twenty-six cases in which the cause was unknown, these three factors would be in the majority. Heredity plays an important part in the causation of paretic dementia,

though I do not think as important a one as alcohol and syphilis, as it acts more as a predisposing cause.

The disease, as a rule, does not attack either extreme age or youth, but on the contrary seems to select individuals in the prime of life. In summarizing these ninety cases, I find that among the men, the youngest case when attacked was 26 years old, and the oldest 63 years; the average of the 77 cases being 41 years and 8 months.

Among the 13 females, the youngest was 21 years of age, and the oldest 56 years, the average being 41 years and 6 months.

In regard to duration, my cases show that among the males (50 cases) the longest time for the disease to run its course was ten years; the shortest, six months. Average of the fifty cases, two years and seven months; and among the females (8 cases) the longest was six years; the shortest, one year and six months; average, two years and eight months. Average of fifty-eight cases, male and female, two years, eight and one-half months.

I have here only taken those cases in which the disease has completed its course, *i. e.*, resulted in death, as some are still here, and others were, for various reasons, discharged.

I think a fair average of the course of the disease is from two and one-half to three years, though, as we have seen, the course in single cases may be varied to either extreme.

The time spent in the hospital by these patients is as follows—and here, again, I shall only consider those cases resulting in death, omitting those which are still here, and those which have been discharged. Among the fifty male cases, the longest residence in the hospital was seven years, the shortest, eight days; average, one year and nine months. Among the eight female cases, the longest residence was three years and two months, shortest, three months; average one year and six months. Average for the fifty-eight cases, one year and seven and one-half months.

The average duration before admission was, males, one year and one month; females, one year and two months.

The ages at deaths were as follows: Males, oldest, 65 years; youngest, 29 years; average, forty-four years, three months. Females, oldest, 58 years; youngest, 26 years; average, forty-four years and two months.

I shall not draw any conclusions from these cases, as I would only repeat those of other writers, but leave that to my readers.

We must realize that if this disease continues to gain ground, and go on increasing, we will have another powerful factor which will aid in the mental, moral and physical deterioration of the American people as a whole.

There is room for improvement in our mode and manners of life, and the sooner we realize it the better it will be for this and future generations.

THE STATUS EPILEPTICUS.

Dr. Robert T. Edes, in the *Virg. Med. Month.*, says: The name "status epilepticus," is, or was, applied to a continuous succession of epileptic fits, coming so rapidly that one does not end before another begins; that is, if we count as a fit not only the period marked by active convulsive movements, but the stage of unconsciousness succeeding it.

This is the usual condition, but it is probable that the same, or a similar, pathological state prevails, and may very properly bear the same name where the convulsions are not all very well marked, but are indicated, or at least some of them are so, simply by muscular twitchings not developing into general convulsions.

Rise of temperature, pulse and respiration are characteristic symptoms; and some others noted in my case, as the extremely dirty tongue, and the rapid supervention of sloughing of the nates, have been commented on before.

In the more typical cases, the status epilepticus is divided into two stages—one marked by the severity of the convulsions, and a second comatose, delirious, or collapsing, which has been termed, though improperly, the meningitic stage.

In looking over the recommendations of authors for treatment, one finds that they agree chiefly on one point, the uselessness of a large number of drugs.

Nitrite of amyl, however, seems to have been of considerable value. It was tried, but not very successfully, in our case first reported. In the other, it was of decided advantage. Amylene hydrate has also been highly spoken of.

In one case he was confident that ether had a decided effect in postponing the attacks, and chloral hydrate, in not excessive doses, by the rectum, was even more efficacious. How far chloral, if used early and freely, might have been efficient, not merely in checking the convulsive movements, but in preserving life, is not so easy to say. It

certainly seems to me that, either alone or combined with bromide, it gives the best chance of attaining this object.

It is not, however, so easy to be certain of this, for the reason that in some cases, and some fatal cases, the severe muscular contractions are not the most prominent features, but the coma and fever, with a few well-marked convulsions, and a more or less constant, but not violent muscular twitching, seems to constitute the disease.

In the comatose stage, or that of collapse, chloral would certainly not seem indicated. He was surprised not to find it even mentioned in either of two monographs * founded on an apparently thorough study of the subject.

A phenomenon, which is sufficiently often seen to have been considered by some writers essential, or even diagnostic, is a moderate and usually evanescent hemiplegia. This has been wrongly attributed to some gross permanent lesion in the brain, which by no means invariably exists.

In one case, nothing of the kind could be observed, although repeatedly and carefully looked for. The only possible indication of any unilateral affection was the turning of the eyes and head to the right for a few seconds at the beginning of a fit.

In another case, there were differences of sensation and slightly of motion in the two sides, but the only gross lesion noted was in the median line.

A CASE OF PSEUDO-CHOREA.

When first seen at the out-patient department the most conspicuous features about the case were clonic movements of some of the muscles of his trunk, which jerked the latter forcibly to the right side, the diaphragm being affected at the same time, so that a grunting inspiratory sound was produced which often interrupted his speech in a quite characteristic manner. His gait was hemiplegic and the muscular strength was found to be distinctly subnormal on the entire right side, the movements were confined to the trunk and followed each other in quick succession. The motions of the limbs were found only to be communicated. The man was totally unable to walk alone.

As regards his family history, we were told that the patient's father had died with an acute brain-trouble, the exact nature of which, however, could not be ascertained. The patient had been well and strong. No excesses *in Baccho aut Venere.* No syphilis. In 1888 he entered the army. In 1889 he was in Washington Territory with his regiment and much exposed to wet and cold. During the next summer, following a good deal of exposure, he was attacked with severe pain in his back, which shot down into his legs, especially the right one to the toes. The joints were neither swollen nor red, but the attack was of considerable severity, so that, as he states, he was unable to walk for between two to three months. While still at the hospital, he had an attack of the same nature as the present one, which persisted for four months and gradually disappeared. With the exception of a very slight return in the spring of 1890, he remained perfectly well until 15 days before he was first seen. While driving a wagon the axle broke and he was thrown out. He was not hurt, but two hours later the jerking movement referred to above suddenly appeared.

Two days after presenting himself at the dispensary he was admitted to the hospital, the condition was then slightly better. A more careful examination was made. The latissimus dorsi., the rhomb., the serrat., were found to be especially affected. The pectoralis less so. Of the abdominal muscles the rectus. The diaphragm as stated above. The weakness of the right side still well marked. Some tenderness over the errect. spinae.

About the movements the note, which was dictated by Dr. Lafleur, says: "the movements are of great rapidity and have almost a rhythmic character jerking his body to the right in a manner which reminds one somewhat of the canine chorea."

The viscera showed no changes.

He was found to have dulling to sensation of pain (not of touch or of heat) in the whole right side with the exception of the face. There is diminution in the reflexes on that side. The perimetric fields of both eyes were equal and normal. The special senses are in no way affected. Electrically there was no change found.

The patient was placed in a room by himself and no medication save a placebo was given.

The improvement was rapid and remarkable. He slept comfortably, the jerks diminished in frequency and four days later only occasional movements were observed, and still three days later they had almost completely ceased. Now the only features remaining are the sensory changes and the changes in the reflexes. The resemblances

* Hertz.—Status Epilepticus. *Inaug. Dissert., Bonn, 1877.* Lorenz, *op. cit.*

to Sydenham's chorea exist of course only in a rough way. The points which are unlike the true chorea, are: (1) the almost rhythmical character of the movement; (2) the electric-like character of them; (3) the fact that they were confined to the trunk; (4) the sensory changes; (5) the fact that in a quite short time the movements reach the greatest severity.

The case, therefore, must be classed under the head of Pseudo-chorea, which belongs under the large heading of Hysteria.—Dr. Hoch in the *Johns Hopkins Hosp. Bull.*

SURGERY.

MICROCIDIN—A NEW ANTISEPTIC.

At the meeting of the French Academy of Medicine, held in Paris, April 28, and reported in the *Bulletin Médicale*, April 29, 1891, Dr. Polaillon read a paper on the subject of microcidin, a new antiseptic which has recently been discovered by Dr. Berlioz.

A quantity of *B* naphthol is heated to the melting point, and the half of this quantity (by weight) of caustic soda is added and the mixture allowed to cool. The result will be a white powder composed largely of naphthol and soda, but besides this composites of naphthol and phenol, which give the substance peculiar properties which seem to justify the name of microcidin, which Berlioz has given it.

The substance is soluble in three times its weight of water. Concentrated solutions are of a brown color, while the weak solutions are almost colorless. It is but very slightly toxic. Its antiseptic properties are weaker than those of bichloride of mercury and naphthol, but it is ten times as strongly antiseptic as carbolic acid in solutions of similar strength. The toxicity of microcidin is less than that of naphthol, and, of course, infinitely less than that of bichloride of mercury. The substance is almost entirely eliminated through the urine.

Regarding the clinical value of the preparation, Polaillon has used a 3 per cent. solution of microcidin with excellent results in leg ulcers, various suppurations and suppurating wounds. The solution is non-irritating, promotes healing, and keeps the wound clean.

SURGICAL AND CLINATIC TREATMENT OF PHTHISIS.

An interesting monograph on the above subject has been recently published in German, by Dr. C. Spenglar, of Davos (Switzerland).

The author claims that neither cavities, empyeman or pyo-pneumo-thorax can heal unless the necessary mechanical conditions are brought about. Arguing from this point Spengler advocates the establishment of an open pneumo-thorax, by a free resection of ribs. In advocating this procedure he places himself on the same stand as Schede and Immermann. In young subjects the method promises better results than in older patients. The principle consists in the hypothesis that the atmospheric pressure on the lung would cause a shrinking of the thorax. Of course, there is always more or less displacement of the organs of the chest, especially the heart, but not enough to cause any untoward effect. This treatment should be supplemented by a careful dietary, hygienic and climatic treatment—high altitudes being preferable. Finally, Spengler cites many cases which show the efficacy of the treatment, although in many cases sufficient time had not elapsed to warrant a more than improved condition.—*Centralblatt für Chirurgie*, April 25, 1891.

SURGICAL TREATMENT OF APPENDICITIS.

Dr. Randolph Winslow, in approaching this subject from a surgical standpoint, states that there was great difficulty experienced from the confusion in the nomenclature applied to the inflammatory troubles in the right iliac fossa, and that this confusion in nomenclature meant an equal obscurity in our ideas of the pathology of these affections.

The terms typhlitis, perityphlitis, and paratyphlitis, are used more or less indiscriminately for painful inflammatory affections of the right flank, which may be widely different in character.

Typhlitis is an inflammation of the cæcum, which may be limited to its mucous coats, or may penetrate more deeply, until the peritoneal coat is reached, when the resulting peritonitis, with its accompanying exudation, is called *perityphlitis;* and if pus forms, a *perityphlitic abscess* is said to be present.

It was supposed until quite recently that the cæcum was only partially covered by peritoneum, leaving a large part of its walls with no peritoneal coat, and in immediate relation with the post-cæcal connective tissue. This is an error, the cæcum has a distinct mesentery in the vast majority of cases, and floats quite freely within the

peritoneal cavity. And when an abscess forms, it is almost invariably found to have its primary seat within the peritoneal sac—the diffusion of the pus being prevented by adherent coils of intestines. Sometimes, as a secondary result, the peritoneum is destroyed and the pus escapes into the post-peritoneal connective tissues. It would be much better to use the terms cæcitis and appendicitis to describe inflammations of the cæcum and vermiform appendix, and to discard such expressions as typhlitis, perityphlitis, and paratyphlitis, as being obscure and obsolete. *Cæcitis or typhlitis* is a disease amenable to medical measures, and but seldom calling for surgical treatment, whilst *para-* and *peri-typhlitis*, meaning thereby an inflammation of the post-cæcal connective tissue, but seldom occurs.

As the various inflammatory conditions within the female pelvis are usually found to depend upon disease of the Fallopian tubes, so the inflammations found in the right iliac fossa usually have their origin in diseased conditions of the vermiform process. It is very important, therefore, that we should have correct ideas about this very troublesome and apparently useless bit of anatomy.

The *vermiform appendix* varies in size, length, and position; sometimes it has quite a distinct mesentery, but generally it is quite free, and may be found occupying almost any relation to the cæcum. Its tip may be found in the pelvis or turned upwards and attached to the abdominal wall or some of the viscera, or the whole process may be found behind the cæcum, or in fact occupying almost any relation to this gut.

It is probable that the appendix is frequently diseased without producing very decided or distinct symptoms, and that recoveries occur both with and without treatment.

When, however, *acute appendicitis* sets in, the symptoms are generally quite characteristic; but it is not every case of acute appendicitis that demands operative treatment. When the symptoms are not very severe, the pain not intense, and the fever not high, and especially if no tumor is to be felt, reliance should be placed upon medical treatment; a careful watch should, nevertheless, be kept for evidences of the development of more threatening symptoms. Even where there is a swelling found in the right iliac fossa, it does not necessarily demand operation. He has seen a number of cases recover after a decided exudation had occurred, without operation or any appeciable discharge of pus.

It has been recommended, and in many cases carried out, to aspirate the suspected region. Whilst this method has yielded good results, he is unable to approve its employment, as it is excessively hard to properly disinfect an aspirating needle, and a serious accumulation may become converted into a purulent one, besides the risk of penetrating the intestines or some blood vessel. When the diagnosis must depend upon the detection of fluid within a circumscribed space, it will be less dangerous to make an incision down to the seat of disease, than to aspirate.

When a decided lump is found in the right iliac fossa, which is hard, tender, and painful, and the fever keeps up, and especially if this lump increases in size, an incision should be made both for purposes of exploration and treatment. This incision should not be too long delayed, as the pus may break through the adhesions which circumscribe it, and set up a general suppurative peritonitis. It is not safe to wait until the sign of fluctuation can be detected, as this may never occur, or may occur only at a late deriod. The earlier the operation is performed the greater the probabilities of a successful termination. It may be stated that operations, when indicated at all, ought to be made as early as the fifth or even the third day.

When the symptoms of perforation come on, as sudden and intense pain with collapse, operation ought to be performed as soon as there is sufficient re-action to justify it; otherwise a generalized peritonitis will probably set in and terminate fatally. There are a few cases of perforative appendicitis, which present such obscure symptoms, that the nature of the disease is not suspected until a fulminent peritonitis is set up, with pus-bathed intestines and viscera, when it is too late to save the patient by laparotomy.

Dr. Winslow thinks we should emphasize the fact that the exudation, or pus, in a case of suppurative appendicitis, is found within the peritoneal cavity, and not in the post-peritoneal connective tissues; hence, the great danger that the adherent coils of intestines may become separated, and fatal general peritonitis occur.

Having determined to operate, the seat of incision is usually over the swelling, as thereby the most ready access to the abscess cavity is gained. The tissues are divided by a straight or curved incision in the right flank until the transversalis fascia is reached, when an aspirating

needle or hypodermic needle may be thrust in various directions into the swelling, if there is any doubt about the presence of pus, or the tissues may be cautiously divided until the peritoneal cavity is opened, when the exudation of pus or serum will be reached. If the appendix is perforated, or even if it is manifestly diseased, it should be ligated close to the cæcum and cut off. Sometimes the appendix will not be found—it has sloughed off and disappeared. It is usually better not to irrigate the abscess cavity, as there is danger that by so doing pus may be forced into the general peritoneal cavity. Free drainage should be secured, and as far as practicable, antiseptic treatment adopted; but this will be difficult, as the discharge is of an especially septic character.

As surgeons, we are also called upon to open the abdomen in those cases where the pus has set up a general peritonitis, though with but slight hope of success. Here the incision should be placed in the linea alba, with perhaps incision for drainage for one or more other points. The peritoneal cavity should be thoroughly cleansed, the intestines sponged off or washed, and free, and if possible, continuous irrigation with warm water, or a weak antiseptic solution kept up—several drainage tubes being placed in favorable situations. One or two cases have been recorded of recovery after continuous irrigation for several days.

A certain quite large number of cases of appendicitis recur after having apparently healed, and not only give rise to considerable local reaction, but even to danger.

Treves, of London, and Senn, of Milwaukee, recommend the removal of a diseased appendix during the intervals of quietude from acute outbreak, and report several successful operations in such cases. Dr. Winslow is strongly inclined to the opinion that this is correct surgical doctrine, notwithstanding the protest of Dr. Dennis, of New York, against it; and he will certainly carry it out in practice in appropriate cases. Dr. Winslow referred to a patient who has had two attacks of painful febrile affections on the right side of the abdomen, the first of which was recovered from under medical treatment, and the last, after incision, who is determined to have the more radical operation performed if he has another recurrence.

In conclusion Dr. Winslow submits the following propositions:

1st. Inflammatory affections in the right iliac fossa are atmost invariably due to diseased conditions of the appendix vermiformis.

2nd. When an abscess forms in the course of such affections, the pus is found, primarily, within the peritoneal cavity, and not in the post-cæcal connective tissue.

3rd. Many mild, and some severe attacks of appendicitis are recovered from without operation.

4th. When there is severe localized pain, tenderness, and a tumor present in the right iliac region, with the constitutional suppurative inflammation, an early operation is demanded to evacuate the pus. This should be done as early as the third day when possible.

5th. Delay is more dangerous than operation, as the adhesions circumscribing the pus may give way, and a rapidly fatal peritonitis may be set up.—*Virg. Med. Month.*

GYNÆCOLOGY.

INCISION VERSUS RAPID DILATATION FOR STENOSIS OF THE CERVICAL CANAL.

Dr. James H. Reilly in a paper before the *Vermont Medical Society* said: I feel that I owe the society an apology in claiming that better results can be obtained in the treatment of constriction of the cervical canal for dysmenorrhœa and sterility than by the more modern procedure, rapid dilatation, as advocated by Goodell and other eminent gynæcologists; but after an experience in the treatment of forty cases, my statistics force me to take the stand that I have taken.

When cases of this kind first came under my direct observation for treatment, I resorted to the operation by means of rapid dilatation as a means to produce a radical cure. I assisted at the operation a great many times during my service as hospital interne, and whilst I looked upon the operation as a barbarous procedure, it evidently accomplished the dilatation to such a marked degree that I reconciled myself with the idea that the end justified the means. That the canal could contract again to the same degree as before operation appeared at that time to me an impossibility, but it was not my privilege to watch the progress and termination of these cases after leaving the hospital, and, not hearing of any unsatisfactory results, I concluded that the operation must have been very gratifying to the operator as well as to the patient. After entering practice, when cases of this nature

presented themselves to me, the first operation that suggested itself was that of rapid dilatation; and after meeting with cases where, after dilatation to the maximum extent (suggested by enthusiastic advocates of the operation), and carrying out the after-treatment in the manner advocated by them, the contraction was as marked as before the operation, if not to a greater extent, I have concluded that the operation does not overcome, to a permanent degree, the contraction of the cervical canal.

The causes for which we are called upon to do this operation generally are dysmenorrhœa and sterility. When I say dysmenorrhœa and sterility, I do not mean to say that all cases of painful menstruation are due to a constriction of the cervical canal, nor that all cases of sterility are due to this condition. I have only reference to those cases where every other reason is excluded and a stenosed condition of the cervical canal exists. When called upon to treat a case of sterility, I think we are justified in operating if this condition is found to be present, although history of dysmenorrhœa is not associated with the case, a condition not at all uncommon; in fact, the only case of sterility which I have successfully treated by rapid dilatation is that of a woman who presented herself to me for treatment with the following history: She had been married eight years, was twenty-one years of age when married, and had never had any serious sickness. She was very anxious to have children, and stated that if the fact that she had none was due to any condition that could be corrected she wanted to have it done. She menstruated regularly, and never had severe pains immediately before or during this period. There was no ulceration around the external os. On passing the sound it met with considerable resistance at the internal os, and was forcibly passed through. The uterus was found to be in its normal position. The only condition about her that I found to which her sterility could be attributed was this apparent constriction at the internal os. I dilated this rapidly under ether, passed a sound at short intervals for a month, after which I did not see her for four or five months, when I was called to see her for some of the disagreeable symptoms of pregnancy, and in a year from time of operation I delivered her of a twelve-pound boy.

Of the forty cases that I have operated upon, ten were for sterility and thirty for dysmenorrhœa. On the first ten cases that came under my observation for dysmenorrhœa I operated by rapid dilatation, and of these but four were relieved permanently. The condition of six others, after periods varying from three months to a year, was as bad, and in two cases worse, than before operation. They underwent a secondary operation by incision, and after a period of from one to two years I have yet to hear of an unfavorable result. Of the remaining thirty cases operated on by incision, permanent relief followed in every instance. Within the last six months I have operated on three cases which I have not included in my statistics, as I do not regard a case permanently relieved until they pass a period of one year without a recurrence of the trouble. Of the ten cases operated upon for sterility, six underwent the rapid dilatation operation. This operation proved effectual in but one case, and that as reported. After one year's time the contraction was as marked as before the operation. They underwent a secondary operation by incision. Two of them have borne children, and one other is well advanced in pregnancy, and in one the constriction is as marked as before the operation. The other patient passed from under my observation about six months after the operation. She was not pregnant at the time. On four patients I have done the operation by incision during the past year; two are now pregnant—one two months after the operation, and the other four months. On two I have operated within the past three months, and they are still under my observation.

The constriction in every case that came under my observation has been at the internal os. In not a single case have I met with any resistance with the ordinary sound until I came to the internal os, and in every instance the constriction has been so marked that an ordinary probe could not be passed unless considerable force was used. What we accomplish by dilatation is a paralyzation of the sphincter muscle surrounding the internal os, but it is only a temporary paralysis, and will gradually resume its functions again in the same manner as the sphincter ani, and after forcible dilatation for diseases peculiar to the rectum. The great tendency for this muscle to contract again after dilatation is not at all surprising. Very true, the muscular fibres that are ruptured by the dilatation lose their power of contractility, but it is almost an impossibility to rupture them all with the instruments devised for rapid dilatation, and I doubt whether we will rupture any of the fibres if only carried to the extent

advocated by some authors. When we reflect and consider how soon after labor, where the muscle surrounding the internal os is put upon a stretch to an extent of six times as great as can be accomplished by any of the dilatation instruments now in use, and how soon after it resumes its power of contractility, it is inconsistent to expect to deprive the same muscle of its function under the force of the instruments devised for that purpose. The operation by incision is not attended with any more danger than by rapid dilatation. A number of instruments, called hysterotomes, or metrotomes, have been devised to do the cutting. The objection to these instruments is that they do not incise deep enough. In my hands the long, blunt-pointed bistoury has accomplished the desired result without any trouble.

Pelvic peritonitis or cellulitis is a contra-indication for the operation; in fact, it is essential that any inflammatory trouble peculiar to the pelvis should not exist to have the operation successful. If the operation is done and any inflammatory trouble exists, the operation is certain not to be a success, but the inflammatory condition aggravated. This does not include endometritis; but, on the contrary, when this disease exists, which it does very often in consequence of a stenosed condition of the internal os, the cure of it is facilitated by the opening of the os.

The operation should be done as soon after the menstrual period as possible. This will give the tissues sufficient time before the next period to become completely healed. If the tissues are in an inflamed condition at the subsequent period, contraction is very sure to follow; for this reason a patient should not be operated upon close to a menstrual period.

A mild cathartic is given the night before the operation. If this does not prove effectual by time of the operation, the bowels are unloaded by means of a rectal enemata. A vaginal douche is given the morning of the operation; this leaves the parts in a proper condition for the operation. The various steps in the operation are as follows:

The patient is anæsthetized and placed on a table, and a bivalve speculum introduced, or a Sims, whichever is preferred by the operator. The cervix is grasped by the forceps tenaculum and held in a fixed position. A dilator is passed to open the os up to a degree large enough for the bistoury to enter. After passing the bistoury, the next step is to make the incisions. I resort to the crucial incision, one anterior and one posterior and two lateral incisions. A blunt-pointed, double-edged bistoury has been devised to simplify the operation by avoiding turning the instrument. I use the single-edged one, and do not experience any difficulty in turning it from one wall to the other. The depth of the incision is governed by the experience of the operator. The danger of a deep incision lies in the severing of the circular artery. As near as I can determine, the depth of the incision I usually make is about three-eighths of an inch. The hæmorrhage is controlled by compression with absorbent cotton passed into the canal on an applicator. Occasionally I have found it necessary to resort to applications of the persulphate of iron to control the bleeding. A douche of hot water is again given, a stem pessary introduced and held in place by tampons saturated with a solution of glycerine and carbolic acid (ten grains to the ounce), a hypodermic given, and cold applications are kept over abdomen for about four days. A vaginal douche is given once a day for about ten days. If symptoms of pelvic inflammation develop, the pessary is taken out and a sound or dilator passed every few days, and hot applications are to be made instead of cold. It is the exception for inflammatory symptoms to develop. The patients generally make uninterrupted recovery, and are able to be around the tenth day. The pessary can generally be left in for three weeks before removing. If the period is due before that, it will be essentially necessary to remove it at the expected time. The patients are instructed how to place tampons themselves. If the operation is for dysmenorrhœa, sounds should be introduced a few days before the expected period; if for sterility, I generally wait until after the period before their introduction. If the patients are not carefully observed and dilatation kept up for a year after operation, it is certain not to prove effectual.

DRAINAGE OF THE ABDOMINAL CAVITY AFTER LAPARATOMY.

While the majority of German gynæcologists practice the immediate and complete closure of the abdominal wound after laparotomies, a number of the foremost operators, both in England and America, speak in favor of abdominal drainage. Dr. M. Sänger, has recently performed fourteen laparotomies in which he has used drainage, and he claims to be forced to the conclusion that the course of such cases is much safer and less

critical than when drainage is omitted. Finally, the danger of poisoning by blood ferments is entirely obviated. There are three forms of abdominal drainage: first, the tubular drainage, with straight or bent glass tubes; second, the intra-abdominal tampon, with absorbent gauze; third, a combination of the glass tubes and absorbent gauze.

In eleven of the cases reported by Sänger, in the *Deutche Med. Wachenschrift*, the last named method was employed. A most carefully cleaned and sterilized bent glass drainage-tube was used, its sides being perforated with a number of small holes. After closure of the abdominal wound, several strips of absorbent gauze were placed in the tube by means of a similarly bent copper sound. Over all this an antiseptic and if possible an hermetically closed bandage dressing was applied. The dressings were renewed in twenty-four hours.

OBSTETRICS.

STRYCHNIA AND THE HOT DOUCHE IN THE PROPHYLAXIS OF PROTRACTED LABOR.

The following observations on the use of small doses of strychnine, given for a period prior to labor, may prove interesting. From a therapeutic point of view they are certainly useful.

I have given strychnine in one hundred cases, and the effects, as far as the children were concerned, were very gratifying. Out of the entire hundred births there were only two children still-born. One of these had evidently been dead in utero for some considerable time, and was quite macerated and softened. The other was lost by the twisting about the neck of a short cord.

With regard to the mothers, the strychnine acted as a bitter tonic and improved the appetite; its use stimulated the movements of the bowels, and to some extent prevented the constipation that is so general in pregnancy. At the time of labor not one of the patients treated with the strychnine had convulsions, so that it cannot be regarded as unsafe for this reason. Its action on the uterus was satisfactory, the contractions being regular and normal, and entirely free from any tetanic condition, as is sometimes seen after the administration of ergot during labor.

The state of uterine tone was improved by the strychnine. The contractions of the uterus were longer maintained, more regular and satisfactory, than in the case of those to whom the strychnine had not been given. The after-contraction of the uterus was better, and after-pains were greatly lessened, as the firm condition of the uterus prevented the formation of clots and the occurrence of jerky, twitching, clonic uterine action that is often so distressing to the patient. The amount of hæmorrhage was reduced. There is an impression in the minds of many that the bleeding after labor is arrested by the formation of clots in the uterine sinuses. Such, however, is not the case. The uterine vessels are surrounded by the interlacing muscular fibres of the uterus. It is the steady, firm contraction of this muscular tissue that must be regarded as the true hæmostatic, and not dead, inert clots.

Another feature well noted in the cases where strychnine had been given was that the recovery was quick and better than the average. There are several reasons for this. The shorter period of labor must have had some influence. Then the fact that there was less blood loss is important. The firm tone of the uterus, effecting speedy and good involution and controlling the after-pains, also had its share in aiding the recovery. Good, firm uterine tone lessens the risk of septic absorption, and by so much favors the patient's recovery.

Concerning the duration of labor, the following figures may assist in conveying an idea of the general usefulness of the drug. It should be remarked the treatment was adopted in cases where previous labors had been protracted owing to uterine inertia, irregular and crampy pains. Primiparæ were excluded in all cases. The one hundred cases treated with the strichnine gave an average of nine hours, whereas the average of the previous protracted labors, in the same one hundred patients, was seventeen hours. Here we have an average gain of eight hours on previous tardy deliveries, the second stage being much shorter.

The dose of the drug varied with the susceptibility of the patient. One could not tolerate more than the sixtieth of a grain. A number had reached their maximum dosage when taking one-fortieth three times daily. About one-half of the entire number bore the thirtieth of a grain well. The largest dose given in any case was the sixteenth of a grain three times a day. This amount was administered to one patient, who, during two prior labors, had almost complete uterine inertia.

It is quite possible that other tonics, such

as iron and quinine, would exert a beneficial influence where there was anemia and debility.

As a means of prophylaxis against a protracted first stage caused by a rigid and undilatable os, I strongly recommend a hot douche. All are familiar with the excellent effects of this measure in the first stage of a lingering labor, but it has not been used as prophylactic against a tedious first stage due to rigidity of the maternal tissues. The plan I have adopted is to take a new tin pail holding about two gallons, and have a small spout put on the side near the bottom. To this are attached a few feet of rubber tubing carrying a good vaginal nozzle. The pail is filled with water at 105° to 110° F. The patient sits over a receiving vessel; the nozzle is then introduced and the flow started. In this way the cervix and vagina are thoroughly douched. One caution is needed —that the hydrostatic pressure be not too great. All that is requisite is just enough to make the water flow.

It may be said that the use of the hot water will induce labor before the full term has been reached. Such, however, has not been the case in my experience. But grant that it should come on a few days sooner than it would if the douches had not been used, what harm could there possibly arise from such a circumstance? If there is not too great force in the water flow, so as to effect some separation of the membranes, there need be no fear on this score.

The douche ought to be used twice a day for a short time before labor, a week or ten days being sufficient to soften and relax a very rigid os. The local application of the hot water stimulates the blood supply of the pelvic viscera, increases the activity of the glands, and allays much of the sensitiveness of the cervix. When labor sets in the os yields sooner, is less tense and less liable to tear. The first stage is in this way very materially shortened. The abundant secretion of mucus aids the second stage. The second stage is also shortened by the relaxing action of the douches on the perineum; it, like the os, is found to yield to the pressure of the advancing head, and time and suffering are saved.

These douches may be ordered with advantage in all cases where rigidity and slow dilatation is probable, as in primiparæ, or where previous tedious labors have been known to be due to tense and rigid structures. Many patients of this latter class have gone through subsequent accouchements with comparative ease and rapidity after the use of the hot water for ten days prior to term.—*Dr. John Ferguson, in Amer. Jour. Obstetrics.*

RETAINED PLACENTA IN MISCARRIAGE—HOW SHALL WE TREAT SUCH CASES?

Dr. A. J. Swaney in the *Southern Practitioner* writes:

The reasons given for active interference are the frequency of these dangers in prolonged delivery of the placenta. The almost constant possibility of manual extraction which at once assures the woman's safety from the dangers of hæmorrhage and septic poisoning, Simpson, Munde and Grandin are perhaps the most active partisans for interference. Simpson directs if the cervix is dilated, or patent to act at once, if it is not dilated, he dilates at once. The woman is first anæsthetized, the uterus depressed as much as possible by the external hand and with the index finger of the other hand, he removes the placenta and membranes. If he cannot sufficiently depress the uterus with the hand, he does not hesitate to forcibly drag it down by a double tenaculum fixed in the cervix. Mundé and Dr. E. H. Grandin, of New York, go still further, and currette the cavity of the uterus with special instruments made for the loosening of adherent placenta and its removal from the uterus. These curettes have no cutting edge and are applicable to cases where there is a large mass to remove, and where in consequence nearly always the cervical canal is open and will admit them. When dealing with shreds and the os is less patent, the dull curette of Thomas answers every purpose. They place the woman in the left lateral position and the removal is through a Sim's speculum. Dr. Grandin then directs, after the removal of the placenta, that the cavity of the uterus should be carefully dried by cotton applicator and tamponed by a slide applicator, the cotton on which has been saturated with the compound tinct. of iodine. The compound tinct. of iodine is used as a gentle styptic and disinfectant, or if there is much fetor iodoform is preferable. The authorities who counsel waiting for serious complications before interfering are just as many. We mention Ramsbotham, Davis, Burns, Fleetwood Churchill, Grailey Hewitt, Charpentier, and many others. Charpentier, in his *Cyclopœdia of Obstetrics and Gynœcology*, says:

"If the woman miscarries in two stages, if the fœtus has been expelled and the placenta remains, what is to be done? Usually nothing: nature can do the work.

The placenta may remain days before being expelled; whilst there are no complications, wait at least till the placenta is engaged in the cervix and detached from the uterus, and then extract. If the placenta is not engaged and the cervix is closed, wait, and in case of hæmorrhage tampon, give ergot, never the ergot alone. If the placenta is still adherent, and is in part engaged in the cervix, give ergot, for the cervix cannot contract, since its canal is filled by the placenta. If the placenta is at the fundus and adherent, wait in case there are no complications, but interfere in case of accident. If it be hæmorrhage, the tampon and ergot. If it be putrefaction of the placenta, recognize this and extract at once; we must not hesitate, but we must immediately extract the placenta or secudines, and this, it is understood, is all the more difficult, the more completely the cervix has closed. If the cervix is permeable to the finger or instruments, the operation is easy. If closed, then we must dilate at once with sponge, branched steel dilators, or with Barnes' bags. Dilatation once accomplished, we must proceed to extraction, and this must be done by the finger or instruments, according to the case. He directs after the cervix has been dilated, and the woman on her back, to depress the uterus with the left hand as much as possible, and with the index finger of the right hand introduced into the cavity of the uterus, or as deep as possible, the adherent remnants are detached and brought away. If this does not suffice he resorts to instruments."

Septicæmia being one of the dangers from putrefaction of the retained placenta, how are we to recognize this. The first symptom is fetor of the lochial discharge. The discharge further loses its normal character and diminishes in quantity, becoming in color black or brown. It is no longer bloody or sero-sanguinolent, but is composed of reddish-black detritus, the debris of the retained mass, involution ceases and the uterus becomes sensitive to pressure. At times tympanitis supervenes with or without diarrhœa. The woman has chills. Sometimes the chills are violent and single, at other times many, separated by intervals of one or two days. There is fever, the temperature rising to 104°, 105° F. The pulse ranges to 120 or more. The temperature shows a marked remission, but the pulse remains high, and thus it may be day after day until the woman dies, or the fever may be continuous. The general condition alters for the worse. The eyes are sunken, anorexia and vomiting exist, the woman grows weaker, and if we cannot suppress these symptoms, dies of septic poisoning.

Has the physician any business to allow a woman with retained placenta to enter such a state as this? Is he doing his duty to sit calmly waiting for the onset of sepsis? He knows what he ought to do in case of sepsis, but action then, no matter how prompt, may fail, and the woman die of septicæmia. Then, as we cannot tell in any given case of retained placenta or secundines whether or not sepsis may develop, which is the wise course to pursue? To sit calmly waiting for the approach of these dangers, as advised by Charpentier, Ramsbotham, and others; or to act promptly, as advised by Mundé, Grandin, and others? I believe with Munde and Grandin, that active interference in the removal of the retained placenta is safe, easy, and forthwith guarantees the woman against sepsis. Active intervention does not mean unnecessary intervention. Nature is ever to be given a chance, but when we see her efforts are futile, certainly it is but rational to assist her, and this should be done as directed by Mundé and Grandin, by placing the woman in the left lateral position, and with a dull wire curette remove the placenta or any part of the secundines that may remain through a Sims speculum. This is far better and easier than the method advised by Simpson, of dragging or pressing down the uterus and introducing the finger into the uterine cavity. The uterine cavity should then be washed out with hot water slightly carbolized through a Jamson uterine douche, and repeated every six or eight hours until all fetor disappears from the lochial discharge.

I am painfully aware of the fact that a very large majority of physicians follow and practice the expectant or do-nothing plan, being satisfied with giving ergot and vaginal injections. It would doubtless be a surprise to many if we could ascertain the number of valuable lives that have been lost and the amount of suffering entailed upon women from the neglect of removing the retained placenta. Who of us with much experience has not seen such cases?

Shall we give ergot in retained placenta? This is another practice which should be relegated to the past. Engleman says never give ergot until the uterine cavity is cleared. The contractility evoked by ergot is notably different from that which is peculiar to the uterus; it is a species of tetanic contraction which, when it affects the cervix, not only

does not cause dilatation, but produces rigidity. Ergot may then act directly opposite to the end desired, and by interfering with dilatation of the cervix shut up the uterine cavity. Hæmorrhage after miscarriage, even when we believe the placenta and membranes have been removed, invariably means retention of a part of the placenta or secundines. Profuse hæmorrhage may occur for weeks from this cause. In such cases we should boldly explore the uterine cavity and remove any offending matter that may be present.

In the first twelve weeks of pregnancy, the dangers from hæmorrhage and septicæmia are not so great, and the expectant plan is more justifiable. After the third month it is criminal negligence to wait and subject a woman to the dangers arising from retained placenta, when she can be relieved by an operation, which, if properly done, can do no harm and spare her the risk of hæmorrhage and septic poisoning.

Again, with Mundé and Grandin, I repeat. The early removal of the secundines is easy, safe, and forthwith guarantees the woman against the dangers of hæmorrhage and sepsis.

It has been said that necessity is the mother of invention. I now show you an instrument improvised and made fifteen years ago by Dr. Thomas M. Woodson, of Gallatin, Tenn. As you see, it is simply a wire doubled and twisted together, leaving an open space at the end, as the wire is brought back. This opening is about one-half to three-quarters of an inch wide and two inches long, and is then again bent to resemble a spoon. This is as good a curette as Tieman can make, and was devised and used by Dr. Woodson to extract a retained placenta in a miscarriage of five months pregnancy. He has used this frequently and successfully, and in case of emergency it will answer every purpose. Some months ago I saw a lady who had miscarried at five months. Five days after the fœtus passed, a retained placenta was passed by the unaided efforts of nature; four days after this, I saw her in a dying condition with septicæmia. Was it proper to allow the placenta to remain such a length of time? Was this a wise course to pursue? Who can say: "This valuable life might not have been saved by the early removal of the retained placenta?" This case prompted me to present this paper for your thought and consideration.

TREATMENT OF POST-PARTUM ECLAMPSIA.

Dr. Strisover contributes a most interesting article on the treatment of post-partum eclampsia in a recent number of the *Journal de Méd. de Paris.* The treatment advocated by him, and used successfully in every case (ten) in which he has had occasion to try it, consists in hypodermic injections of the following solution:

℞ Chlorhydrate of Pilocarpine, gramme.....o. 05
Water.....4. ∞

Each injection to consist of a Pravaz syringeful of the solution.

The author closes his article with the following conclusions:

I. Chlorhydrate of pilocarpine is undoubtedly a trustworthy remedy in post-partum eclampsia.

II. Cardiac weakness is not a contra-indication for the repetition of the injections of pilocarpine if the eclamptic spasms reappear.

III. A return of the pupils to the normal size is an indication that the morbid process has not yet been conquered, and that the convulsions are about to recur.

PÆDIATRICS.

ETHERIZATION IN CROUP.

Dr. F. Betz contributes an article to the current issue of *Memorabilien*, which, though founded on only one case where etherization was tried as a treatment for croup, is yet of sufficient interest to merit notice. He commenced by pointing out that in croup the tendency towards death is by no means commensurate always with the morbid condition of the larynx anatomically considered, the nervous system often playing a considerable *role.* The case he describes was that of a child thirteen months old, to whom he was called by another practitioner in order to assist in the performance of tracheotomy. The child was breathing with the greatest difficulty, expiration and inspiration being equally noisy; the hypochondriac regions were strongly drawn in at each inspiration, also the lower intercostal spaces anteriorly; the alæ nasi were working strongly, and the child kept clutching at its throat, where the larynx was very prominent, and at its ears, and twisting its head round as if there were both pain and a sense of obstruction. It would not drink or stay in bed, the face wore an anxious expression, and the head was retracted. No membrane could be detected in the throat, and there was no sound of air entering the lungs when auscultated from behind. On the left side

percussion was dull from want of expansion of the lung. Altogether the case was apparently hopeless. Notwithstanding the dangerous character of tracheotomy in children so young, preparations were made for its performance, when the writer suggested that ether inhalations should first be tried. A mixture was ordered of three parts sulphuric ether, one part acetic ether, and one-tenth part menthol, of which three drops were given as an inhalation on a folded handkerchief every quarter of an hour. The idea was by means of the vapor of ether and menthol to act on the mucous membrane of the larynx, which, as is well known, lies somewhat higher than usual in croup, and thus to contract the bloodvessels, to lower the temperature of the part, to decrease the œdema, to lessen secretion, and to allay the irritation in the larynx by the production of some amount of local anæsthesia. In addition to these, Dr. Betz had the further object in view of inducing partial general anæsthesia so as to give the child rest, and to allay the spasmodic contractions of the muscles connected with respiration. In a couple of hours a decided change for the better had taken place, the child being quieter, and some air evidently entering the lungs. The inhalations were continued, therefore, but at intervals of half an hour. Six hours later the respiration had become much less noisy, the contractions less, and the dyspnœa far less urgent, enabling the child to drink. The face had regained its proper color, and the child was apparently pretty comfortable, so that there was no longer any need to think of tracheotomy. The regular administration of the inhalation was stopped, but another mixture of somewhat similar character, containing three-tenths of a part of menthol, was ordered, in case of any recurrence of the alarming symptoms. Fortunately the subsequent progress was so uniform that no recourse to this was required. The object of increasing the menthol was to obtain greater refrigeration and to enable it to penetrate further into the air passages. The writer remarks that Trousseau used to prescribe chloroform inhalations in croup, but he is disposed to prefer his own mixture of ether and menthol. Whether such etherization has any power to loosen false membranes further experiments must show; but when tracheotomy or intubation is for any reason inadmissible in undoubtedly membranous croup, this treatment may, he thinks, very fairly be tried. The inhalations ought not to be continuous, but intermittent, and the medical man should for the first hour or two administer them himself.—*Brit. Med. Jour.*

HYGIENE.

PROGENY OF LEPERS.

In an analysis of 118 cases of leprosy in the Tantaran Asylum, in the Punjab, reported by Gulam Mustafa and read before the Epidemiological Society of London, by Dr. Phineas S. Abraham, we find the following relative to the progeny of lepers: Seventy-three of the total number appear to have been married before the onset of the disease, viz., forty-three males and thirty females; and whilst still in the healthy condition, the males are credited with seventy-one children, now or lately living, and in most cases free from the disease, and the females with sixty-five; total, 136. Only four females are stated to have given birth to offspring, five in all, after the disease had declared itself. Until recently, it was the custom to allow the patients to intermarry. Thirty-nine of those whose histories are recorded, viz., sixteen males and twenty-three females—availed themselves of the privilege, and seven of them married more than once; thus, one man united himself with no less than five leper wives, one after the other, and several other patients were married two or three times. Altogether, the number of marriages contracted by the men in the list amounts to twenty-six, and those of the females to twenty-nine. Only five of the men proved prolific, with a result of ten children and eight of the women with a result of fifteen children. Four of the children are dead, so that we have left twenty-one as the progeny of fifty-five marriages. As the notes give no information as to the names of the leper or lepers which each man or woman married, it is impossible to say whether the children and the marriages are not counted twice in the above collection. It is probable that the actual sterility is even greater than these figures indicate.—*St. Louis Med. and Surg. Jour.*

TRANSMISSIBILITY OF SYPHILIS.

As published in his magnificent *Atlas of Venereal and Skin Diseases*, Prof. Morrow's conclusions in reference to the hereditary transmissions of syphilis are:

1. A syphilitic man may beget a syphilitic child, the mother remaining exempt from all visible signs of the disease;

the transmissive power of the father is, however, comparatively restricted.

2. A syphilitic woman may bring forth a syphilitic child, the father being perfectly healthy; the transmissive power of the mother is much more potent and pronounced, and of longer duration, than that of the father. When both parents are syphilitic, or the mother alone, and the disease recently acquired, the infection of the fœtus is almost inevitable; the more recent the syphilis, the greater the probability of infection, and the graver the manifestation in the offspring.

3. While hereditary transmission is more certain when the parental syphilis is in full activity of manifestation, it may also be effected during a period of latency when no active symptoms are present.

4. Both parents may be healthy at the time of procreation, and the mother may contract syphilis during her pregnancy, and infect her child in utero. Contamination of the fœtus during pregnancy is not probable if the maternal infection takes place after the seventh month of pregnancy.

MEDICAL CHEMISTRY.

SOLUBILITY OF IODOFORM IN OLIVE-OIL.

The solubility of iodoform in the fixed oils is stated somewhat variably. Squire gives 1 to 30 of olive-oil; Martindale "1 in 60 of vaseline and oil of almonds, and about the same in fats and other fixed oils." F. Klingmann (*Apoth. Zeit.*, 1891, 70) has recently determined the factor with care. Five grammes of iodoform were added to 30 grammes of olive-oil, the whole been shaken for twelve hours by means of a small turbine. Then it was filtered, and the saturated oil was found to contain between 2½ and 3 per cent. of iodoform. With due allowance for specific gravity, this shows the solubility of iodoform to be 1 part in 39 fluid parts of olive-oil.

UROLOGY IN CONNECTION WITH INFANTILE DISEASES.

Albuminuria.—The citro-picric acid reagent of Esbach is approved. First, filter the urine, then pour a few centimeters of it into a tube, and then an equal quantity of the reagent. If there is albumen the mixture will become opalescent, or there will be a precipitate. Frequently it may be necessary to reach the boiling point before the precipitation will take place. Examinations for albumen were made in two hundred and fifty cases. In twenty-seven cases of pneumonia and broncho-pneumonia, albumen was found in large or small quantity. Albumen is usually associated with febrile oliguria; it disappears with defervescence and increases in the urine. It is a characteristic of all infectious diseases, though the rule is less absolute in children than in adults. In measles, albuminuria was present in 33 out of 34 cases, in scarlet fever in 34 out of 43, in erysipelas in 4 out of 5, in febrile roseola in 1, in typhoid fever in 5, in diphtheria in 36 out of 40; it was absent in 1 case of mumps and 2 of false croup. Albuminuria is transitory and not intense in most diseases with the exception of diphtheria, though in scarlatina it is present in a serious and rather permanent form in the secondary nephritis, which may occur as a complication. The albuminuria of diphtheria has no relation to the existence or intensity of the fever. It is present in fifty to seventy-four per cent of cases. In 10 cases of pulmonary tuberculosis albuminuria was present in 5, and in 4 out of 6 cases of tubercular meningitis. In 6 cases of whooping-cough it was found only once, in 1 case out of 3 of athrepsia in very young children, in 2 out of 3 cases of scrofulous cachexia with adenitis, in 1 case of acute perityphlitis, and in 1 of extensive burning. In 21 cases in which there was suppuration, especially in connection with carious bone, there was albumen in 11. Of 27 cases of nephritis, 21 occurred with infectious diseases, and 6 as chronic nephritis.

Peptonuria.—The peptones are hydrated albumens, soluble in water, diffusible, dialyzable, and not precipitated by heat, nitric acid, ferro-cyanide of potash, and acetic acid. They are easily precipitated by most of the reagents which precipitate the alkaloids, the precipitate being redissolved by heat and reappearing with cold. The reagents which are most frequently employed are phospho-tungstic acid, phospho-molybdic acid, tannin, iodo-iodurated solutions, iodo-mercuric and citro-picric solutions. The search for this substance is made in the same way as for albumen. If a precipitate is obtained it may consist of albumen, peptones, alkaloids, or urate of sodium. If it should be albumen, it will not be dissolved when heat is applied. If it should consist of alkaloids or peptones, heat will dissolve it, but the alkaloids, and quinine in particular, will respond to particular reactions for such substances. The acid urate of sodium forms a finely granular precipitate

which appears more slowly than a precipitate of peptones; the latter will also give an opalescent appearance.

If there is any doubt remaining, it may be settled by the murexide test. If the urine is albuminous, the albumen may be eliminated by Hoffmeister's method. Eichwald and Gerhardt were the first to determine the presence of peptonuria, in cases of pneumonia, diphtheria, phosphorus poisoning, tertiary syphilis, petechial typhus, and dothinenteritis. Jaksch discovered it in certain conditions in which there was change in the blood, scorbutus being one of these conditions. In the general infectious diseases it is usually absent. Peptonuria has been divided into the following groups: nephrogenic, pyrogenic, puerperal, hæmatogenic, enterogenic, hepatic, and urogenic. The blood normally contains no peptones, hence its presence indicates a non-assimilable material which the kidney should eliminate. Peptones were sought by the author in 248 cases of disease in children, and were found in 34. It was found in 5 cases out of 28 of pneumonia and broncho-pneumonia, in 1 case out of 2 of purulent pleurisy, in 1 case of severe febrile roseola, in 10 cases out of 37 of diphtheria, in 3 cases out of 21 in which there was suppuration, in 1 case out of 6 of athrepsia, in 13 out of 23 of nephritis. In the 34 cases of peptonuria there were 32 in which there was also albuminuria. The methods of investigation now in use are not yet sufficiently exact.

Diaceturia.—If to normal urine a solution of perchloride of iron is added, there will be a precipitate of phosphate of iron; if perchloride of iron is still added, the precipitate will be dissolved and the urine will assume an amber color, or, in other cases, the color of red wine, which will become less marked by boiling, and will disappear if acids are added. These reactions will not take place if the urine is first submitted to prolonged boiling. Jaksch considers this reaction due to aceto-acetic acid or its ethers, and he has given the name diaceturia to the elimination by the urine of its acetic acids, its salts, and its ethers. He has determined its presence in diabetes and in several febrile diseases, and has also found that it might exist as the expression of a particular auto-intoxication. Febrile diaceturia is of frequent occurrence but is not of serious prognostic significance.

In diabetes it is a grave symptom, and frequently announces the advent of coma. In 150 examinations the author determined diaceturia in 69. It was found 19 times in 23 cases ot pneumonia and broncho-pneumonia, in 16 out of 26 of measles, in 27 out of 34 of scarlet fever, in 4 cases of erysipelas, in 11 out of 31 of diphtheria, in 2 out of 13 cases of suppuration, in 2 out of 4 of typhoid fever, in 2 out of 4 of tubercular meningitis, in 1 of acute perityphlitis, in 1 of extensive burning, in 2 out of 15 of acute nephritis, in 1 of solid tumor of the iliac fossa. Diaceturia may be considered as of frequent occurrence in infectious febrile diseases, and particularly in scarlet fever. It occurs exceptionally in uncomplicated diphtheria.—Binet's—*Rev. Mens. Mal. Enf.*

NEWS AND MISCELLANY.

Result of Koch's Treatment.—According to the *British Medical Journal*, 708 cases have been treated in external tuberculosis, 15 cured, 148 substantially improved, 237 improved, 298 unimproved and 9 died.

MODERN DISCOVERIES OF NEW CURES.

With painful and patient pen we record the birth of a new treatment for phthisis, the sixth in four months. The hopeful author and discoverer this time is Dr. Tranjen, of Sistow, Bulgaria. He doesn't seem to have any front name, but that may be the fashion in Sistow. Professor Dr. C. A. Ewald writes a supplement to Dr. Tranjen's communication and also publishes the details in all their rosy tabulated promise in the *Berliner Klinische Wochenschrift*, an organ for practical doctors. The refrain which Dr. Tranjen plays upon Professor Ewald's organ is like that of other discoverers. We are having prepared a lithographed form for the benefit of future ingenious therapeutists in this same line. It will read like this:

"*Form* I.—Dr. —— has discovered a new remedy for phthisis. He reports . . . cases. The results have so far been very satisfactory. In early stages it produces decided improvement and sometimes cure. In later stages it does not do so much good, but sometimes causes remarkable improvement before the patient ultimately dies. Dr. ——'s new treatment promises to be a useful addition to our therapeutic armamentarium, and deserves further trial."

We shall be very glad to furnish "discovery blanks" of the above type to our clinical workers.

But meanwhile we had almost forgotten to say that Dr. Tranjen's new discovery consists in the hypodermic injection daily, for seven to ten days, of a solution of thymoloacetate of mercury, at the same time giving the patient iodide of potassium. The results are accurately described in Form I, as given above.—*Med. Rec.*

ARISTOL.

While possessing all of the virtues of iodoform, and many properties not claimed for the latter **ARISTOL** has **NO TOXIC INFLUENCE AND NO DISAGREEABLE ODOR.**

The efficacy of **ARISTOL** has been widely tested by physicians and surgeons. As a simple dressing it now **HEADS THE LIST OF LOCAL REMEDIAL AGENTS,** and the results obtained in the **GREAT VARIETY OF MORBID LESIONS** for which it has been employed, have been wholly satisfactory.

ARISTOL has been widely commended for its special adaptability to all surgical and pharmaceutical requirements. It may be used in the form of **OINTMENTS, CRAYONS, SUPPOSITORIES, BALLS, OILS, SPRAYS, COLLODIONS, POWDERS, PLASTERS,** Etc., while it is equally suitable for **TAMPONS, BANDAGES, GAUZE,** and other topical appliances. Used as a powder, it forms **AN IMPERVIOUS ANTISEPTIC COATING,** which gives it an exceptional value in **ULCERATIONS, BURNS,** Etc.

ARISTOL has been used with unqualified satisfaction by able and experienced clinicians in **DERMATOLOGY, SYPHILOLOGY, GYNÆCOLOGY, OPHTHALMOLOGY,** Etc., and in all of those diatheses in whose course such lesions supervene as call for **ACTIVE, LOCAL MEDICATION.**

ARISTOL is demonstrated to possess **EXCEPTIONAL EFFICACY AS A CICATRISANT.** In **ULCERATIONS,** of whatever character they may be, in **BURNS,** and in **ALL OPEN LESIONS,** the efficacy of **ARISTOL** cannot be overestimated.

Hence its great value in the **DERMATOSES,** the **SOLUTIONS OF CONTINUITY** dependent upon **PHTHISIS, SCROFULOSIS, SYPHILIS, VARIX** and accessible **TRAUMATISMS,** and in the **SUPPURATIVE LESIONS** following many inflammations. Its value in **BURNS,** as in all the operations of **MINOR SURGERY,** is exceptional, while in **DENTAL SURGERY** it has given very valuable results.

Applied to the **MUCOUS SURFACES** of the **NATURAL CAVITIES,** in such conditions as **PHARINGITIS, RHINITIS, OTITIS METRITIS, URETHRITIS,** etc., etc., **ARISTOL** gives the same excellent effects as in tissue lesions.

☞ Physicians are respectfully requested to test for themselves the accuracy of these statements, while reading in our pamphlet of the results obtained by others. *Pamphlet mailed to applicants.*

The preparation of **ARISTOL,** theoretically simple, involves the greatest care and experience, and the word **"ARISTOL"** is the registered property of *The Farbenfabriken, vormals Friedr. Bayer & Co., in Elberfeld.* In order, therefore, to secure the desired effect of **ARISTOL,** it is important that the physician be certain that the article used bears the name of these manufacturers, together with the name of W. H. SCHIEFFELIN & Co.

W. H. Schieffelin & Co.,

NEW YORK.

JOHN C. BAKER & CO.'S
STANDARD PREPARATIONS.

Messrs. JOHN C. BAKER & Co.

Gentlemen:

It affords me pleasure to have the opportunity of recommending your Cod Liver Oil to the medical profession. I feel satisfied that a purer and more efficacious article can not be obtained in the market.

Yours, with respect, JOSEPH LEIDY,

Professor of Anatomy in the University of Penna.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

Baker's Cod Liver Oil and Malt Extract.

SOLUTION FERROUS MALATE,
SOLUTION SALICYLATE IRON,
BARLETT'S PILE SUPPOSITORIES.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,
OFFICE AND LABORATORY
815 FILBERT STREET,
PHILADELPHIA.

DR. GARRETSON'S work on the *Diseases and Surgery of the Mouth, Jaws, Face, Teeth and Associate Parts* is the only thorough treatise on the subject. So much new matter has been introduced in the *Fifth Edition*, recently issued, as to make it obligatory upon every dentist, who desires to keep abreast of the advance of thought, to add this standard work to his library. Price in Cloth Binding, $9.00. Sheep, $10.00.

DR. J. M. DACOSTA'S *Medical Diagnosis* furnishes some of the most entertaining medical reading to be found in our modern literature. So much of the text has been rewritten and so much of intrinsic value has been added to this new *Seventh Edition* that the practicing physician can not well afford to be without the work. In Cloth Binding, $6.00. Sheep Binding, $7.00.

For sale by all Booksellers, or, will be sent, free of expense, on receipt of the price.

Clinical Lecture.

SYPHILIS WITH LESIONS OF THE HEART AND KIDNEYS.

BY CHARLES G. STOCKTON, M. D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE, UNIVERSITY OF BUFFALO—VISITING PHYSICIAN TO THE BUFFALO GENERAL HOSPITAL.

This is not an easy case to diagnose by exclusion, and I shall, therefore, go directly to the ultimate cause of his difficulty and then we will try to account for his more immediate troubles.

A few months ago, this man acquired syphilis, and he is now suffering with the secondary manifestations of that disease, feverishness, weakness, mucous patches in the mouth, and specific pharyngitis and laryngitis. You have seen him in the wards and you understand that while these are manifestations of importance, they are conditions that can usually be readily relieved by the use of mercury, and the symptoms pass off under a careful administration of this drug in a comparatively short time, particularly if the patient is, at the same time, well cared for, well fed, not allowed to worry, not allowed to drink alcoholic beverages, and compelled to keep regular hours. Under this treatment the man has done badly, he very soon showed tenderness of the gums and salivation, so that the mercury had to be withdrawn, and his throat trouble became worse. Then mercury hypodermically was tried and injections of the bichloride were made once daily until the effects in the mouth were shown and then it was discontinued to be tried again after three or four days. Once in two or three days is often enough for hypodermic injections of mercury if you use large enough doses. We used in this case one-eighth of a grain daily. You may give a half a grain and allow two or three days to elapse before the next dose. Under this treatment the man has gotten the good effects of mercury but he has had considerable throat trouble, and one night he had indications of œdema of the glottis, a croupy cough, the symptoms of laryngismus stridulus, and we felt it necessary to have means at our disposal for relief if the condition became worse. The O'Dwyer tubes were put in readiness, but under the use of an alkaline steam-spray, he improved, and, while he is yet voiceless and yet suffers to some extent from cough, he is decidedly better. Not getting any relief for his throat symptoms by the use of Gross's mixture, which we gave first, nor by the use of mercury hypodermically, I began giving him mercury in the form of the green iodide by the mouth, and under that, I think, he is doing better, so far as his throat is concerned, than he did under the hypodermatic use of mercury—a matter of therapeutic interest because it is contrary to what is generally stated in regard to the relative value of different modes of employing mercury.

I bring the man before you this morning, not in regard to his ultimate disease, but on account of certain manifestations of the disease in the viscera. He is very anæmic; he is eating and digesting very little. He has great prostration and I discovered some time since that he had a curious pulse. It was a pulse suggesting the Corrigan pulse and yet not well enough sustained in the beginning to make a true Corrigan pulse. It was frequent, very compressible and vibratory. My attention was naturally directed toward the heart and I found that the man was suffering from a present endocarditis which showed itself by the soft bruit, the somewhat tumultuous action of the heart as well as the curious character of the pulse. This endocarditis was located in the left side of the heart where it almost invariably occurs in adult life, and affecting especially the mitral and aortic orifices. Later I found that this man was suffering from œdema. His hands are somewhat puffy, the fingers seem large

in proportion to the size of the hand and the skin is distended and glossy. Before saying that this was the result of the disease of the heart alone, I asked that the urine be examined with a view to learning whether there was also kidney disease present and it was found that there was a large amount of albumen in the urine. We have here not only secondary syphilis with serious throat trouble, but a present endocarditis and nephritis. The form of nephritis which he has, I cannot state to you without making a careful microscopic examination of the urinary sediment, estimating the urea, studying the relation between the quantity of urine and the albumen, but in all probability it is an acute desquamative nephritis, coming on, as the heart trouble has come on, since his entrance into the hospital, and, therefore, secondary to the attack of syphilis. Why do I make a diagnosis of *acute desquamative* nephritis? The large amount of albumen and the brevity of the duration of the symptoms make me think that the case is an acute one, and if so, it is probably of the parenchymatous form.

Let us look at the patient generally, before we study more carefully the condition of his heart and kidneys. The œdema is seen very plainly in his legs, his feet are swollen and are quite red, showing a congestion which is unusual in œdema. There is no dermatitis, either simple or syphilitic and it is not a temporary condition, due to the recent application of heat. The congestion of the capillaries is probably due to some affection of the sympathetic system.

The œdema is undoubtedly due to the heart and kidney lesions. The state of the blood might add to the condition. You may ask if the liver may not have something to do with causing the œdema. That is possible, although general anasarca we refer, as a rule to disease of the heart, kidneys or blood. Dropsy due to the liver, is usually an ascites, and not a general anasarca, unless the hepatic trouble acts to interrupt the general circulation in some very marked way, or unless it gives rise to serious blood changes such as take place in cancer of the liver. An acute neuritis might give rise to an œdema, but our patient has no evidence of neuritis. Anasarca may also be due to the obstruction of the flow of blood through the lungs by disease of the lungs, but this man shows no further trouble in the lungs than the overfilling of the vessels with blood, which is readily explained by the heart disease.

The endocarditis, being acute, will probably get better in course of time; just how much deformity of the valves will remain, it is impossible to say. The apex-beat is in the fifth intercostal space, about an inch and a quarter below the nipple and a trifle to the right of the nipple line. At the apex I find a bruit which precedes the ordinary systole of the heart, and is, therefore, a presystolic bruit. It is accompanied by a considerable thrill at the apex and just above it. The presystolic sound is heard in the same locality with the greatest intensity. It is caused by an obstruction and narrowing of the mitral orifice due to swelling, possibly œdematous, of the leaflets of the valve. If the man improves, this condition may entirely subside, or it may leave behind a permanent narrowing of the mitral orifice. It may leave merely a shortening of the valves and an insufficiency. There is also a systolic bruit. The presystolic bruit ends in the systolic bruit in the somewhat excited state of the heart at present. The blood is forced down by the contraction of the auricle making the presystolic sound and, on account of the insufficiency of the valve, some of the blood is immediately returned by the contraction of the ventricle giving rise to the systolic sound. Both the presystolic and the systolic sounds are soft and cooing in character, and when the patient is lying down at rest there may be heard very distinctly, three sounds at the apex instead of two. The first two sounds come nearer together. The first sound is the murmur produced by the contraction of the left auricle; the second the regurgitant murmur produced by the contraction of the left ventricle, and the third sound is the ordinary second sound of the heart caused by the closure of the aortic valves. None of the heart sounds have their natural accent, they are all obscure and have a certain bluntness, a certain muffled character which is the result of the œdema, which is present in the heart. The systolic sound is carried upward and to the left as we would expect, and, while I can not hear the sound behind, it is simply because it is not distinct enough to be propelled to that distance.

The man has also disease at the aortic orifice and that I know by the character of the sounds at the base of the heart. There is heard, with the first sound of the heart, a soft bruit, which travels upward into the vessels of the neck and which is also muffled and obscure. The second sound of the heart is nearly normal. There is a sharp accentuation to it now because the man is somewhat excited and his arterial tension is

higher than normal. When he is in bed this sound, too, is muffled and with it there is a slight murmur of insufficiency. He has disease at the mitral and aortic orifices, both obstructive and insufficient in character, which may be entirely temporary, which is produced by an acute endocarditis and also by a profound anæmia which causes softness and relaxation of the cardiac tissues.

This man has an acute inflammatory degeneration of the kidneys as the result of syphilis. I have no doubt of the syphilis possibly involving the blood-vessels of the kidney, and also directly attacking the epithelium and giving rise to a cloudy swelling and softening and desquamation of the epithelium. Tube casts are produced, epithelial, hyaline, granular and, probably, to a certain extent blood-casts. The amount of urine is doubtless small and the urea is decidedly diminished. Those waste products which are normally formed in the blood and which are formed to an abnormal degree in this man's case, are not thrown off properly by the kidneys and the man has a uræmia, strictly speaking, and other toxæmias also.

What are we to do for the patient? We must deal with the cause certainly. The syphilis must be treated and the most important remedy in the treatment of the secondary stage of syphilis is mercury. He does not bear mercury well and he already has the mercurial breath which you will learn to recognize instantly so that you can tell it on first entering a house in which there is a patient with mercurial stomatitis. It is my belief that we will have to overcome the syphilis by the moderate use of mercury. It does no good to force mercury beyond the point of tolerance. The present tenderness about the teeth will pass away in a few days and we must continue with such a dose of mercury as to keep his gums slightly tender.

We must attend to his fever and relieve it, especially by baths. We must nourish most carefully, avoiding alcoholic stimulants if possible. The patient's diet will be chosen from the following list: milk, eggs, peptonized beef, peptonized milk punches with just enough whisky to give a flavor, oyster broth or oysters themselves peptonized, forcing nutrition as far as we can.

The utmost attention must be paid to the bowels. While we are doing this we must bear in mind that what he takes must come out of him in some way. If he takes food and it is assimilated, it passes into the blood and the waste products from the blood pass out chiefly through the kidneys normally, but in his condition, the waste products will not pass off through the kidneys. This is one of those cases which tax the skill of the physician and on which physicians so often go wrong. We must treat this man as being sick, as having syphilis, as a patient with Bright's disease, not forgetting that he has a heart trouble.

How shall we treat him for the Bright's disease? Would there be any objection to giving this man vapor baths to stimulate the skin to the utmost and thus get rid of the waste and relieve the kidneys? There is only one objection to that and that is the possible effect on the heart. I shall put this patient upon a treatment of the skin by diaphoretics and diaphoretic measures rather than diaphoretic drugs. He shall have sweats, he shall be kept still in bed, we will try to unload this accumulation of fluid in the subcutaneous tissue and when we get rid of the œdema, we shall know we are helping the kidneys. In the meantime, is it right to force the nourishment as hard as we can? No, we must not force the nourishment till we can provide for getting rid of the waste. The first thing to be thought of after the mercury is not so much forcing nutrition as looking after the kidneys. Many a case of Bright's disease is lost for the reason that nutrition is looked after to the conclusion of the waste products.

With reference to the heart. It is not always a good plan to produce diaphoresis and relaxation of the skin when the heart is weak, because thereby, blood pressure is lowered and the patient feels the worse for it. I should, however, advise moderate diaphoresis here for reasons already stated and should attempt to sustain the heart by cardiac tonics. The heart tonics are in no way antagonistic to syphilis and some of them are irritating to the kidneys. In this form of Bright's disease, by maintaining the blood pressure, we shall relieve to some extent the congestion of the kidneys and we shall enable the urine to pass out in larger quantities and get rid of urea and other toxic principles in large measure. What heart tonic shall we administer in this case? I should say digitalis in the form of the infusion given in teaspoonful doses and repeated every three or four hours, gradually increasing it if necessary till we have a steady quiet action of the heart and at the same time keeping up the diaphoretic measures.

If his urine is at all irritating owing to

the large amount of acid it contains, I should give him alkalies. An alkaline diuretic is the only one that should be given in a case of acute Bright's disease. Stimulating diuretics are altogether inadmissible since they irritate and damage the kidney. Potassium acetate or a mixture of potassium nitrate, sodium bicarbonate and the double tartrate of potassium and sodium given twice a day will produce alkalinity of the urine quicker than almost any other combination.

If we find that the urine is still scant in quantity, that the amount of urea given off is very small, we will often afford greater relief by giving the acetate of potassium than by giving this alkaline mixture.

Such patients are disturbed by iron. The liver is irritated, the appetite is diminished, the patient becomes despondent and depressed by the use of iron. When his digestion is restored to normal, I should give iron in the form of the tincture of the chloride. In cases of rather chronic Bright's disease, the acid preparations of iron are more useful than the carbonate, albuminate or the other preparations which we select in common cases of anæmia. We may give him bitter tonics, such as quinine and strychnine by and by.

So far as the fever is concerned, aside from the baths already mentioned, we will control that entirely by the diaphoretics.

CHRONIC PHTHISIS.

BY R. C. M. PAGE, M. D.,

PROFESSOR OF DISEASES OF THE CHEST AND GENERAL MEDICINE AT THE NEW YORK POLYCLINIC—VISITING PHYSICIAN AT THE NORTHWESTERN DISPENSARY, ETC.

Gentlemen:—The patient I present to you this morning is a man 47 years of age, who is a laborer by occupation. He was, he says, in good health up to a period of some sixteen months ago, when he began to have a cough, and to lose flesh and strength. He has now some dyspnœa and nightsweats.

As you look at this man and listen to the tone of his voice your suspicions are at once directed to either tubercular or syphilitic laryngitis as present in his case. We suspect, from the subjective symptoms of the patient, as related by himself, that he has phthisis, but to what stage this disease has progressed in his case, physical examination will alone enable us to determine.

Phthisis, as now generally understood and accepted by the profession, not only means tuberculosis, but it also signifies pulmonary tuberculosis. It may be acute or chronic, but whatever form it may assume, whether it be slow or rapid in its progress, it is in every case tubercular.

Acute phthisis may commence as a lobar pneumonia, and instead of resolution taking place, as usual, there are signs of softening in the lungs, followed by excavation, rapid emaciation and death in the course of a few weeks. Acute phthisis may also be a part of that form of the disease known by the name of general tuberculosis, affecting the various organs and tissues of the body at the same time. The physical signs of pulmonary disease are those of bronchitis. This disease is nearly always secondary to some tubercular lesion from which the bacilli are absorbed into the blood, the circulation of the blood in the lung favoring their lodgment in that organ, as the tubercle bacilli do not proliferate readily in the circulatory fluid.

Chronic phthisis may be reduced to two varieties, though variously described under different forms, and these two varieties are known by the name of the catarrhal and the fibroid. Catarrhal phthisis is that form of chronic phthisis most frequently met with in practice, and usually appears at the apices of the lungs. It begins in the apices of the lungs, because those parts are the most liable to traumatism from exposure, and injury to the vessels from imperfect circulation and stagnation of blood. There is also less respiratory motion in this portion of the lung and consequently imperfect ventilation, and less tendency to the absorption of exudation and disturbance of the bacilli.

Fibroid phthisis, the second variety of the chronic disease, is in reality a tuberculous interstitial pneumonia. Like chronic interstitial pneumonia, it leads to bronchiectasis and shrinkage. Before the discovery of the bacillus by Koch, in 1882, chronic interstitial pneumonia and fibroid phthisis were regarded as the same disease. After the discovery of the bacillus these two diseases were separated, one being considered as a form of phthisis, and the other as a chronic pneumonia.

There are, as you know, three stages of phthisis, and a thorough appreciation of these three stages is essential to a knowledge of what you can do for your patient. To this end it is well, then, for us to determine the earliest signs of phthisis. What, then, are the earliest signs by which we can recognize this disease? If the top of the left lung be

affected, it is easier to make an early diagnosis than if it be the top of the right lung, since in health the patient has exaggerated fremitus and pectorophony on the right side, as well as slight dullness on percussion and rude respiration.

Frequency of the pulse and loss of appetite are also among the earliest signs of phthisis. But shall we rely in this connection upon the discovery of the bacillus in the sputum? Or are we justified in waiting before resorting to improved methods of treatment until we find this micro-organism? Unquestionably no. The cough of chronic phthisis is at first dry and hacking. Expectoration is scanty, and even that does not contain the bacilli, as a rule, because these bacilli are few in number and are not readily removed by expectoration. Furthermore, every general practitioner has not the means or opportunity of determining the existence of the bacilli in the sputum, even if they could be found.

Now the question comes up for consideration how are we to determine the present condition of this man? and to that end let us see what conclusion we can reach in the way of diagnosis by a physical examination of his chest.

First, on inspection we notice that the chest is more or less retracted on the right side in the neighborhood of the clavicle, and the heart is somewhat displaced to the left. In perfect health we know that the apex of the heart ought to be normally about 1½ inches below, and somewhat within the line of the left nipple. This is, however, a very uncertain landmark for us to follow. It is a safer guide for us to find the middle point of the clavicle, and a line dropped from this point will determine the nipple line in health. Now, what has caused this man's heart to occupy this abnormal relationship? Pleurisy with effusion would tend to produce this condition; enlargement of the liver and spleen would cause an upward displacement of the heart; enlargement of the heart itself would also tend to displace that organ; but in this case we conclude from the physical signs present that this displacement of the heart is due to contraction from pleuro-pericardial adhesions. On inspection, we notice the apex beat of the heart carried outward from such causes.

After inspection we come to palpation, and note the amount of vocal fremitus present over this man's lungs. We get no vocal fremitus in this case from impairment of voice, but as we ask the man to cough we get more tussile fremitus over the left side than we do over the right. Fremitus is increased in two ways, by consolidation of lung tissue, or by connection along the tubes.

After palpation, we come to percussion. If this man were in a state of perfect health, you would get a slight difference in the percussion note over the right and left lung. In the case of right handed people we get a little more dullness over the right lung and *vice versa* on account of the difference in the thickness of the muscles. On percussion we get marked dullness over the left lung, as compared with the right in this man's case.

From these physical signs we can, therefore, conclude that there is something wrong with this man's left lung. There is present there, more or less consolidation of the lung tissue, and a thickened pleura.

This now brings us to auscultation and this subject brings up the question, What do you listen for when you place your ear to a chest like that? You are simply listening for the respiratory murmur, and this respiratory murmur may be vesicular, bronchial or cavernous breathing. Having satisfied yourself about the character of the respiratory murmur and the vocal resonance, we listen lastly for what are called adventitious sounds, viz., sounds produced in the chest by disease. Of these adventitious sounds there are three classes, viz., râles (rattles), frictions and splashing. We have three varieties of râles, dry, moist and indeterminate.

As I listen over this man's chest under the left clavicle, I get on auscultation the physical signs of a cavity. When we percuss over a cavity, we get dullness as a rule, but in certain exceptional cases we may get tympanicity. In the third stage of phthisis, the pathological lesion is generally a complicated one, and you are likely to have fluid in the cavity, a thickened pleura, and other morbid conditions that go to produce dullness on percussion.

Having now gone over this case thus briefly, and having decided upon the diagnosis of phthisis as the cause of this man's trouble, the question comes up, What can we do for him in his present condition? The treatment of phthisis to-day, it must be borne in mind, is still purely symptomatic. We do not use depleting remedies now, as formerly, but we nourish the patient as well as we can. Keep him in the fresh air, give him plenty of milk, cod liver oil, and easily digested food, and treat each symptom as it develops. Filleau thought that he had dis-

covered the cure of phthisis by injecting carbolic (phenic) acid into the patient's body, to be exhaled by the lungs. Seiler claimed that hydrofluoric acid fumes did the same thing. Then came the Bergeon method. Iodoform, arsenic and creosote have all been tried, but without avail. However useful they may be, no one claims that they can cure phthisis. Recently, the whole world has been moved by the well-known discovery of Koch. Sufficient time has not elapsed to pass upon the therapeutic value of this discovery in the cure of phthisis. But, supposing all is true that is claimed for it, the importance of an early diagnosis, and the prompt application of the remedy is at once apparent.

Now there are certain complications that may arise in the course of phthisis which it may be well for you to know how to treat promptly and efficiently, for these complications may sometimes exhaust our patient's strength to such a degree as to utterly defeat any measure of relief or comfort he may be otherwise likely to obtain. Of the complications that attend phthisis, perhaps the most alarming and, and at the same time, the most dangerous is hæmorrhage. Suppose you were treating a patient in this stage of phthisis who was troubled with hæmorrhage. What would you do to arrest it? You may have a profuse hæmorrhage from the lungs before any physical signs of pulmonary phthisis present themselves. This may be the first objective sign of phthisis that you get, and it is usually a very bad sign. At other times, during the progress of the malady a large artery running across a cavity may rupture and give rise to a profuse hæmorrhage by aneurismal dilatation. Now, every one has a different remedy for hæmorrhage in phthisis. It is well to have but one, and that a safe and ready one. Ergotine with morphia is the one remedy I would recommend you to use for this pathological condition, and you will generally find it very efficient.

Ergotine acts by contracting the fibres of the capillaries, but how morphine acts in this connection I am unable to say, but I know from clinical experience that it does good, it allays nervousness, keeps the patient quiet and prevents restlessness. We know in intestinal hæmorrhage due to typhoid fever, morphine stops peristaltic action of the intestine and favors the formation of a clot.

I saw lately at the Brompton Hospital in England, a case of pulmonary hæmorrhage where everything was tried in vain to stop hæmorrhage in a patient with phthisis and the physician in charge had finally to have recourse to morphia to keep the patient quiet, and 1-3 grains of ergotine hypodermically. This succeeded in arresting the hæmorrhage. Twenty-five years ago at Bellevue Hospital the drinking of a saturated solution of common salt was used with very good result in arresting the hæmorrhage of phthisis, and Dr. Alonzo Clark used to say if that remedy did not stop hæmorrhage from the lungs nothing will. How does salt and water act in this connection? Salt simply acts by drying up the blood, and as it is well to have a reason for everything we do, I give you this reason for the use of salt in pulmonary hæmorrhage.

There is another complication of phthisis I wish to speak to you to-day about, and that is night sweats. These night sweats, we know, weaken the patient considerably, and are a very distressing symptom to have. I wish to tell you that because your patient is in the third stage of phthisis, it is no reason why you should abandon him hopelessly. I have seen such people, when sent to a suitable climate, do very well indeed. When a patient has night sweats, you must do something to stop them, but what medicine are you to give to produce this effect? It is a common practice with dispensaries in this city to give one dram of the tincture of belladonna, in a two ounce mixture of Stokes's expectorant, for this purpose. In private practice it may not be desirable to give this remedy, as it has a tendency to produce hoarseness in your patient, and this is a rather unpleasant thing to happen. I had a very bad case of night sweats in a private patient the other day and the very first dose I gave of this mixture stopped them at once. If this remedy should, however, fail in arresting these sweats, then you may try agaricin in doses of $\frac{1}{8}$ of a grain three times a day and increase this amount till you have given the $\frac{1}{4}$ of a grain three times a day; or better still give your patient the oxide of zinz according to the following formula:

℞ Pulv. zinci ox.....iij gr.
To be taken on going to bed at night.

These three remedies are the most efficient that I know of in arresting the night sweats of phthisis.

There is another good thing about the use of balladonna in this connection, and that is in all cough mixtures for the relief of phthisis we have to give opium to a greater or less

extent. Belladonna mixed in with the cough mixture containing opium counteracts the bad effects of the latter drug.

There is another point I wish to speak to you about in this connection, which may prove to you of some practical interest, for though phthisis is a pretty threadworn subject, I think we can learn something new every time we go over this matter. Suppose your patient has a hectic fever every afternoon, how are you going to treat this complication satisfactorily? Hectic fever, you know, is a very disagreeable complication in the course of phthisis, it keeps your patient emaciated, ruins his appetite and renders him absolutely uncomfortable. I remember the time when these patients used to be given quinine in very large doses for this condition, but without producing any good effect whatever. Quinine will not lower the temperature to any appreciable extent in phthisis, pneumonia, pyæmia, or any other similar affection. It is, besides, a very dangerous drug to use in large doses, as I have seen it given in the case of phthisis. Antipyrine is a good remedy to employ for reducing temperature but it produces diaphoresis in your patient, and that is a condition you do not want to develop in a patient with phthisis. Antifebrine is a better remedy to employ for reducing temperature in these cases, as it does not give rise to so much diaphoresis as does antipyrene. By giving five grains of antifebrine in the form of tablets, in the afternoon, at about one o'clock, and five grains more at five o'clock in the evening, your patient will be enabled to spend quite a comfortable night. It is a rule at Bromptom Hospital to let the temperature alone unless it went over 102° F., though I often bring it down below 101° F., because such a temperature as that gradually exhausts your patient's strength and vitality.

You should not forget to supplement this treatment, as I have now outlined it to you, by sending your patients to some climate where they can pass the greater part of the time out of doors in the open air.

Goldbeater's Skin for Cracked Nipples.

M. J. Blechmann (*Paris Médical*) advises the treatment of cracked or fissured nipples by means of goldbeater's skin. Over the nipple affected after wetting with simple clean water, there is applied a round piece of goldbeater's skin, of about ten centimetres in diameter. The center of the skin is first pierced by a number of fine holes with a needle. The skin takes the form of the nipple and adheres like a second epidermis. It should then be moistened and after each nursing a new piece applied.—*Ex.*

CARIES OF COSTAL CARTILAGE FOLLOWING ENTERIC FEVER—PERSISTENCE OF SINUS AFTER OPERATION—TREATMENT BY METHYL-VIOLET—CURE.

BY J. C. WILSON, M. D.,
PHYSICIAN TO THE JEFFERSON HOSPITAL, ETC.

The following case is briefly reported, (1) as an example of a sequel of enteric fever rare in this country though relatively frequent in Europe, and (2) on account of the result of the treatment:

A gentlemen 32 years of age consulted me on October 9th, 1890, in regard to an open sinus in the lower part of his right chest, near the mammillary line.

He stated that during the summer of 1889 he had, suffered from a severe and unusually prolonged attack of typhoid fever, from which he had, however, made as regards his general health, a satisfactory recovery.

In the early days of his convalescence he had experienced distressing pain, localized in the lower part of the right chest. The painful area was extremely tender upon pressure. In the course of a short time an abscess formed at this point which ruptured spontaneously. The resulting sinus refused to heal and continued to discharge a small amount of thin pus.

The diagnosis of caries of the cartilage of the rib was made and some months later an operation was performed. This procedure, however, failed to give relief, and the sinus continued to discharge thin pus as before, though in smaller amounts; its outlet occasionally closing, only to reopen in the course of a few days under the pressure of the accumulated secretion.

Upon examination the opening was found to be surrounded by pouting granulations; it was somewhat retracted; the neighboring tissues for a distance of an inch or two were infiltrated; the skin congested and bluish.

A probe introduced, passed in a direct course upward and backward a distance of about an inch and a half. Being introduced with the tip bent, it passed behind the cartilage of the sixth rib near its costal articulation. The cartilage was distinctly felt to be roughened.

The patient stated that he had recently been advised to have the affected portion of the cartilage excised. In this I fully concurred. Upon further conversation, the

patient's disinclination to an operation being very great, I proposed the treatment of the wound by methyl-violet, a small quantity of which had been sent me a few weeks before by Dr. Johnstone of Brooklyn who had received it directly from Professor Stilling. It was agreed that the patient should regard this as a clinical experiment.

A small quantity of a five per cent. aqueous solution of the blue pyoktanin was injected by means of a curved dental syringe introduced to the cul-de-sac of the sinus behind the cartilage. Upon the withdrawal of the syringe, the orifice was closed by a pad of absorbent cotton which was held in place by strips of adhesive plaster. This maneuvre was repeated on five occasions, at intervals of three or four days. During this period the infiltration of the skin surrounding the fistula rapidly diminished; the neighboring skin lost its livid hue; the pouting granulations underwent resorption and the discharge practically ceased.

Two weeks after the last injection, namely on the 17th of November, the patient returned. The sinus had closed; the infiltration had disappeared and the slightly indurated, but healthy cicatrix alone remained. A distinct loss of the substance of the cartilage, or its inferior border could be felt. Whether this was the result of the caries or of the scraping at the operation, cannot be determined.

To-day—May 25th, 1891—the patient reports that he has had no further trouble. The cicatrix is thin, pliable and movable.

I desire to call attention to the fact that the solution of methyl-violet used in this case was very much stronger than those usually recommended, and to the fact that the outlet of the orifice was immediately closed by a small pad of tightly rolled cotton with a view of retaining the solution in contact with the walls of the sinus.

The treatment was almost painless, and resulted in a cure which now promises to be permanent, without the loss of a single hour's time on the part of the patient, and without the annoyance incident to a surgical operation.

In view of these facts the treatment of small sinuses, resulting from carious processes, by strong solutions of methyl-violet should be tentatively instituted as a preliminary measure prior to a surgical operation.

Maygrier reports an instance of a female fœtus weighing thirteen and a half pounds. Its total length was 58 cm.

REPORT OF A CASE OF FIBRO-PAPILLOMA OF THE BLADDER, WITH RECOVERY.

BY D. W. CADWALLADER, M. D.,

GYNÆCOLOGIST TO ST. AGNES HOSPITAL, PHILADELPHIA.

M. Q., age 30, was admitted to St. Agnes's Hospital, November 20th, 1889, with the following history:

Has been married 13 years and given birth to eight living children; labors all easy; made good recoveries and never had any miscarriages. In March, 1889 her "sickness" ceased and did not return until June, when she began to have "bearing down" pain and a slight discharge of blood each day. This continued up to August 10th, on that day she passed a mass, which on examination by her, proved to be clotted blood; a similar clot was passed a week later, and about this time she began to have occasional hæmorrhages, which were profuse and which continued to present date; has had over thirty in all, and lost as much as a pint and a half of blood at one time. All this time (from March until June) she had no signs of pregnancy other than a cessation of the menstruation.

On admittance she was extremely faint from loss of blood; was terribly emaciated—in fact, reduced to a *mere skeleton*—and had the appearance of one suffering from some malignant disease. She, however, suffered little or no pain, with the exception of occasional vesical tenesmus, which latter symptom was only elicited by the closest questioning, and which she thought very trivial. At this time she had not noticed any blood in the urine.

She had been under the care of two able physicians, one telling her that she need not expect to recover; the other saying she had a miscarriage, and would require a *curretting of the womb* to insure relief from the hæmorrhages. On examination I found the uterus in a normal condition in every respect, with the exception of a slight laceration of the cervix. There was no evidence that a miscarriage had taken place, or that the hæmorrhages had their origin in the uterus. The ovaries and tubes were in a healthy condition. I, therefore, excluded the uterus as the origin of the profuse hæmorrhages, which had now continued for several months. The urethra at its external orifice presented a laceration a quarter of an inch in extent; and by passing the index finger along on the anterior wall of the vagina, there was

detected a mass the size of a large English walnut; it was somewhat flattened, and to the finger in the vagina was quite firm. It appeared to be on the interior surface of the bladder, extending from the fundus to the neck of the bladder.

Introducing carefully a metallic catheter and drawing off a small quantity of urine—free from blood—the growth could be easily felt with the instrument, in the location already indicated. The growth here—in the bladder—felt softer, with somewhat ragged edges, was not pedunculated but *on the contrary, appeared to have a broad attachment to the posterior vesical wall.*

I asked my assistant to feel the growth with the instrument, already in the bladder, and to use extreme gentleness in its manipulation, as these growths frequently bleed profusely. He, however, made undue pressure on the growth, when, suddenly, a profuse hæmorrhage occurred; the patient must have lost at least three pints of blood, some fragments were also passed.

She was put to bed, with the hips elevated, and measures were taken to counteract the shock. These consisted in the application of ice over the hypogastrium, and in the vagina; and hot water bottles to the extremities, and the administering of a small quantity of whiskey. The hæmorrhage ceased, and but a short time ensued till reaction occurred. For a number of weeks large quantities of milk, with other nutritious diet were given; chalybeates and vegetable tonics employed, and absolute rest in the recumbent position enforced.

A microscopic examination of the fragments passed from the urethra, proved the growth to be *Fibro-Papilloma of the Bladder.* I therefore decided to make no operative interference for the present, preferring *la médecine expectante,* as there seemed a decided tendency for nature to expel the growth.

On November 24th, another hæmorrhage occurred; more fragments were passed. The urine was found to contain blood occasionally; at other times, perfectly free from blood.

These fragments continued to come from the bladder every few days, for a period of about four weeks. No severe bleeding occurred after November 24th, and the patient continued to improve. The examinations which were made from time to time proved the growth to be gradually diminishing in size until she was discharged, January 30th, 1890, much improved. On that date the only traces of the vesical growth was a slight thickening of the posterior vesical wall.

She menstruated naturally the latter end of December; again in January, and continued regular. I saw her in December '90, when she informed me she had been in perfect health since leaving the Hospital. Had not had any hæmorrhages of any kind; had continued to menstruate regularly up till October. On examination I found her about three months pregnant and *no traces of the vesical growth.*

I report the foregoing case, firstly, because there are not any reported cases, to my knowledge, where these vesical growths of the bladder, have been expelled by nature through the urethra, and thus resulting in a cure, without the intervention of an operation; secondly, because until recently there has been but little said or written on the subject, and have been considered extremely rare, while there is but little doubt they are frequently overlooked, especially in the female.

THE MECHANICAL TREATMENT OF UMBILICAL HERNIA IN CHILDREN.[1]

BY J. M. THOMAS CHAPMAN,

BESSEMER, ALA.

These varieties of hernia of late have caused considerable discussion from the medical profession. More able men than myself have handled the subject.

The treatment as recommended has not met with general approvement. To me it seems a little presumptuous that I should advance any new treatment but following the old adage, "In unity there is strength," by combining our ideas as we are working and tending in the same direction, by co-laboring together we may yet reach the goal for which we are striving.

In some of these cases the hernia yields readily to mechanical appliances, it matters not of what kind, so there is pressure enough to keep the intestines within the abdominal cavity. Other cases are more obstinate, and give physicians considerable annoyance.

The treatment recommended by our most able men is not satisfactory.

The cork pad of Erichsen is very seriously objected to for this reason, the pressure is not equal, the resisting force is so great as to cause the aperture through which the hernia has escaped to assume less circular

[1] Read before the Amer. Med. Assoc. May 6, 1891.

outline, and the aperture to enlarge, as its natural tendency is to be displaced.

The treatment of Ashurst being very similar, I will not dwell on it as a whole, his treatment but call special attention to certain points, viz.: He used wax instead of cork, it is to be stripped on with adhesive plaster, and removed from time to time when detached by washing. In children where the cuticle is so delicate plaster of any kind that remains on for any time, abrases the surface and causes the child to cry and fret to such an extent that this treatment is unsatisfactory. A child aged nine months was brought to me for treatment, founded with unbilical hernia. From inquiry I found that the hernia made its appearance in the child when two months old. I tried the various modes of treatment as recommended.

My case did not seem to improve, but, to the contrary, get worse. The family of which the child was a member was very much discouraged, they were unwilling for any operation.

I tried a number of appliances that I constructed with negative results, but one idea leading on to another with the same end in view resulted in making the following, to wit:—

I made a jacket, about 6 inches wide, of silk fabric, nicely padded with sixteen eyelet holds on either side. I used absorbent cotton for padding, as it takes up all the impurities that may arise from the cuticle. It is a disinfectant, and makes the jacket soft and light. I attached anteriorly, and posteriorly over both right and left shoulders, strips two inches wide; these strips are padded the same as jacket, their use is to hold the jacket in place, as its natural tendency is downward. I used a round silk elastic for lacing the jacket, this cord will give easily and is stout enough to adjust itself.

If the flatus in the bowels is excessively abnormal I give a simple laxative which will generally relieve them. I take the pad from the water truss, remove the metallic plate from the silk gauze over the exposed surface by means of silk threads, I then adjust the pad to the hernia and attach the pad to the jacket while in position.

The beauty of this pad is its lightness, and softness, and yet it is sufficiently stout to hold parts in place, without enlarging the aperture.

It does not abrase, and can be worn without any discomfort to the child. When the child is asleep, I recommend that it be removed, and replaced on awakening.

I have used this truss in about fifteen cases, the results have been satisfactory.

I have recommended the use to a number of my brother physicians, and in every case the results were gratifying. I had one made under my own supervision, for my esteemed and honored friend, Dr. W. E. B. Davis, of Birmingham, Ala. He was so much pleased with it that he requested me to prepare a paper on the subject, which I have done. This is only a synopsis, so not wishing to consume too much of your valuable time, I will sum up the advantages of this simple little appliance.

1. I claim that it is light, and yet stout enough to hold parts in place without discomfort to the child.

2. The water pad is such that it will not produce force enough to enlarge the aperture, as we know its natural tendency is to be displaced.

3. It will not abrase, and can be worn, if the bowels should be enlarged, from accumulation flatus, as the silk cord will give to such an extent as to adjust itself to the surroundings.

4. And last, but not least, if it does not obliterate the hernia, it facilitates subsequent retention.

Society Reports.

STATE MEDICAL SOCIETY OF PENNSYLVANIA—FORTY-FIRST ANNUAL MEETING,

READING, PENNSYLVANIA, JUNE 2, 3, 4, AND 5, 1891.

First Day—Morning Session.

The meeting was called to order by the President, Dr. Alexander Craig, of Columbia, Pa., and prayer offered by the Rt. Rev. M. A. DeWolfe Howe, D. D., LL. D., Bishop of the Diocese of Central Pennsylvania. Hon. T. P. Merritt, Mayor of Reading, being introduced by the President, delivered an address of welcome on behalf of the city of Reading.

ADDRESS OF WELCOME.

The Mayor said it had been forty years since the State Medical Society of Pennsylvania, then in its infancy, had met in Reading. Since then the progress of the medical

sciences had been very great, and deserved the warm appreciation and earnest support of the community at large. In his opinion the medical profession was above all others the most self-sacrificing. In the life of a true physician, all thoughts of personal convenience were laid aside. This was especially true of the country doctor.

Many of the members present, continued the Mayor, had not only gained name and fame in their professional careers, but had also won well-earned laurels by active service during our late war. He hoped that the stay of the visiting physicians in Reading would be a pleasant one, and that they would carry pleasing memories away with them. They would be taken over the mountain railways and be shown landscape pictures of nature's own production, that rival any in America, and that when once seen can never be forgotten.

In addressing this assembly of physicians the names of many came to his mind; among the dead being Pancoast, Wood, Gross, Leidy and others, and among the living, Agnew, Pepper, Tyson and Keen.

The Mayor then extended an invitation to the visitors to visit the leading manufactories and industries of Reading, and in closing said: "We are a growing town. We have three Hospitals, one Old Woman's Home, and several other charitable institutions, all well supported. Our schools thrive, our churches are everywhere in the city, and our industries are daily increasing. I sincerely hope that your meeting will be a most profitable one, and trust only that your pleasant relations with us, and the enjoyment you may partake of while here, will be ever linked in your memories among the happiest recollections. Again, in the name of the citizens of Reading, I bid you a hearty welcome."

Then followed an address of welcome by Dr. S. L. Kurtz, Chairman of the Committee of Arrangements, on behalf of the Berks County Medical Society.

ADDRESS OF WELCOME.

Dr. Kurtz said: "Forty-two years have elapsed since your last meeting in this city. A generation of people has been born and died in the interval. Of the members of the Berks County Medical Society, who greeted your organization on that occasion not one is with us to-day, and of the members of the State Society in attendance then, there are but five survivors." Dr. Kurtz then spoke most forcibly on the urgent need and desirability of having the Legislature enact a law governing the practice of medicine in Pennsylvania. The speaker then gave a brief but interesting description of Berks County, which, he said, was an eminently agricultural and manufacturing district. The population of Reading at the date of the former meeting was about 12,000, while to-day it exceeds 60,000. In the meantime the city's manufacturing establishments have also greatly multiplied in number, increased in capacity, and are of a most diversified character. Dr. Kurtz then referred to several things in which he claimed Berks county excelled, mentioning among others the Brown-Segment wire gun, and the Carpenter steel projectiles. He then gave a vivid and interesting description of Mounts Penn and Neversink, Klapperthal, the Highland House, Mount Penn Tower and the Mineral Spring Park, points of interest which the visitors would have the opportunity of seeing. In closing he said that the members of the Berks County Society desired that every visiting member and delegate should not only feel that he had garnered the golden fruit of knowledge and experience during his stay in Reading, but also that his social enjoyment might ever remain as a bright and enjoyable remembrance.

It was then announced that the Postal Telegraph Co. had established an office in the hall for the convenience of the visitors.

Dr. Charles W. Bachman then read the programme, and immediately after, Dr. Charles W. Dulles moved that the report of the Committee on Incorporation, of which he was Chairman, be inserted here instead of during the proceedings of the second day, where it had been placed. The motion was carried and Dr. Dulles proceeded to read the report, which stated that a charter had been obtained and that the present meeting was the first the Society had ever held as an incorporated body. Dr. Dulles presented the charter to the President, who delivered it to the custody of Dr. Atkinson, the Permanent Secretary.

On motion of Dr. Jackson, Thursday morning (third day) was set apart for the consideration of amendments to the constitution, during the time allotted to unfinished business.

The report of the Treasurer, Dr. Dunmire, was then presented, and the assets of the Society shown to be $809.88. During the year $2,709.00 had been received from the various county societies, and $2,097.64 expended.

Dr. Edward Jackson then presented the

report of the Committee on Publication, regarding the publishing and distribution of the Society's transactions. The report was received, and the bills incurred ordered to be paid.

It was moved by Dr. Dulles that the Permanent Secretary be authorized to hold the treasurer's bond for $1,000. Heretofore while the bond has been required, no custodian for the same had been appointed. The motion was carried.

The President then appointed an auditing committee to audit the treasurer's account.

Dr. Murray Weidman, of Reading, offered a resolution providing for the appointment of a committee to consist of one member from each county to collect funds for the erection of a monument in Washington, D. C., in memory of the late Dr. Benjamin Rush, of Philadelphia. The resolution was adopted, and each county asked to nominate one of their members to serve on this committee. Dr. Weidman then presented to the Society a copy of the proceedings of the meeting at which the Society was organized, Oct. 11, 1848. In accepting this gift, the Permanent Secretary stated that these proceedings were extremely rare and that the gift perfected the archives of the Society, none of the proceedings being missing. A vote of thanks was tendered to Dr. Weidman, and the session then adjourned for the morning.

The Afternoon Session—2 P. M.

The afternoon session was opened by Dr. J. Chris. Lange, of Allegheny, who delivered the annual

ADDRESS ON MEDICINE.

This address showed careful preparation and was well received. Dr. Lange stated that a golden era was being entered upon by the Medical Profession, and that great things were promised in the near future. He spoke of the growing inclination of the profession to use proprietary medicines, and vehemently denounced this tendency. He declared that the introduction of such remedies was merely a scheme to make money for their owners, and that their success was a detriment to the profession. There are many reliable and effective medicines being used which are standard, yet many reputable physicians desert these well-tried therapeutic agencies for proprietary medicines which have emanated from the laboratory of the chemist instead of from the clinical experience of the physician. From a medical and ethical standpoint, such conduct is inexcusable.

There being no discussion, Dr. A. B. Brumbaugh, of Huntingdon, delivered the annual

ADDRESS ON HYGIENE.

During the course of his address, Dr. Brumbaugh said that less attention was being paid to ventilation than was proper, and that the most important questions a physician was called upon to answer were embraced in hygiene. Dr. Brumbaugh also advanced the assertion that no case of consumption exists that has not been brought on by dyspepsia, and that many cases are directly traceable to the use of tobacco, which may justly be looked upon as an exciting agent of this disease. Could tobacco, together with its ally, the liquor traffic, be rooted out, one of the most infectious diseases would be greatly mitigated. The licensing of tobacco and liquor, and securing revenue from these sources, is like sending out an army of fiends to mutilate and destroy, and then sending out another to bind up the wounds of the sufferers. Dr. Brumbaugh also spoke at length on the danger of water pollution by cemeteries near the banks of streams in large cities, and spoke of this as a potent factor of disease.

Dr. Wm. F. Waugh was then called upon for his paper on typhoid fever, but failing to respond, Dr. John M. Batton, of Pittsburg, read a paper on the subject of

TAPE WORM.

Dr. Batton cited several interesting cases in which he had been able to remove entire worms, measuring from 2 to 7 yards in length, by the use of turpentine and cocoanut.

Dr. James Tyson, of Philadelphia, in the discussion that followed the reading of this paper, said that cases of tape worm were very rare, and that he only met about one case a year in his practice. The subject was fully discussed by several members.

Dr. John B. Roberts, of Philadelphia, presented a resolution to the effect that the bond of the treasurer be placed in the hands of some reputable Trust Company, to guarantee the faithful performance of his (the treasurer's) duty, and that the annual premium be paid by the Society. The resolution was laid on the table.

An invitation from the Wyomissing Club, tendering the visitors the use of the club-house during their stay, was, on motion of Dr. Ulrich, accepted, and a vote of thanks tendered the club. The session adjourned for the day at 4 P. M.

Later in the afternoon a visit was made

to the Reading Hospital, where the visitors were received and entertained by the Ladies' Auxiliary, and lunch served. The location and excellent equipment of the Hospital afforded the visitors much gratification.

In the evening, at 8 o'clock, the members again assembled in the Academy of Music, where the entire meeting was held, in order to hear the

PRESIDENT'S ADDRESS.

The Academy not only contained members of the Society but also a large number of ladies and guests, so that the large auditorium was well filled. Dr. Craig, the President, was introduced by Dr. S. L. Kurtz, chairman of the committee of arrangements.

At 9 P. M. a reception and banquet was tendered the visiting physicians by the members of the Berks County Medcal Society of

Second Day—Morning Session.

The meeting having been called to order by the President, the following physicians were named for the Committee on Nominations: Allegheny, A. Koenig; Armstrong, J. F. Henry; Berks, H. Landis; Bradford, C. L. Stephens; Bucks, J. N. Richards; Butler, J. C. Cort; Chester, W. R. Perdue; Dauphin, W. T. Bishop; Delaware, W. B. Ulrich; Elk, J. J. Finerty; Green, J. M. Williams; Huntingdon, A. B. Brumbaugh; Indiana, A. B. Ansley; Lackawanna, L. M. Gates; Lancaster, M. G. Motter; Lebanon, J. R. Bucher; Lehigh, M. F. Early; Luzerne, L. H. Tabor; Lycoming, J. G. McCormick; Montour, C. B. Mayberry; Northampton, W. L. Estes; Philadelphia, Bernard R. Lee; Schuylkill, J. F. Bronson; Warren, M. S. Guth; Washington, J. B. Donaldson, and York, S. J. Rouse.

Dr. Ziegler, of Columbia, opened the business by moving a vote of thanks to the President for his able address. The motion was unanimously carried. The first paper of the day was the

ADDRESS ON MENTAL DISORDERS.

Read by Dr. Samuel Ayres, of Pittsburg. Dr. Ayres dwelt principally upon gastro-intestinal catarrh as a cause of insanity. He said that melancholia and disorders of a similar nature were in the majority of instances attributable to a derangement of the digestive organs, or the stoppage of the passage of some duct. A healthy, vigorous body, he regarded as essential to a sound mind. Many other derangements of the nervous system were also due to intestinal troubles. In his opinion many of the mental disorders found in adults begin in childhood, and are due to injudicious feeding. Hot bread, cakes, sweets, and so forth, were the cause of many digestive derangements which result in serious disorders as age increases.

The liver normally acts as an obstruction to, and destroyer of, the poison which enters the system, but when this organ becomes weakened by vicious living, it is no longer able to discharge its duties, and cannot throw off all the poison. There are three recognized forms of gastro-intestinal poisoning. The first by sulphurretted hydrogen, formed by putrifying matter within the stomach and bowels. This condition may justly be called a gastro-intestinal sewage poisoning. The second form is by ptomaines, and the third is a toxæmia. Al these may result in both mental and nervous derangements. In passing cases where the exciting disease is neither aggravated nor chronic, these symptoms may take the form of vertigo or insomnia, and are directly due to the absorption through the digestive tract of some morbid element. If these symptoms become intensified by chronic gastro-intestinal troubles, melancholia or even suicidal mania may be the result. The absorption of toxic matter may frequently occur through the kidneys, and we often find forms of insanity supplementing renal disease—especially Bright's disease. In such cases the uræmic disease is not the primary cause of the mental condition, but it causes a discharge of poison into the blood, and this in its turn, gives rise to the mental symptoms. Science has, unfortunately, not yet advanced sufficiently to enable us to ascribe any one definite cause for insanity, neither has it yet shown us that it is the work of a microbe. The speaker believed, however, that some specific would be found for insanity, and that at no distant day some lymph would be found, the inoculation of which would effectually counteract the poison that diseases the mind.

At present prophylaxis promises more than therapeusis, and the preventive or active treatment of dyspepsia in children is of great importance in this respect. Even cases of melancholia and other forms of insanity have yielded when, by means of active medication, the digestive disturbances have been cured. In such cases all food or drink which is likely to cause rapid fermentation should be avoided. Diuretic elimination is also frequently of great value.

Finally, in children of weak digestion all starchy or saccharine foods should be carefully restricted.

Dr. Israel Cleaver, of Reading, then read a paper entitled:

HISTORY OF THE MEDICAL PROFESSION IN BERKS COUNTY.

The reading of this paper was followed by Dr. H. G. McCormick's

REPORT OF THE LEGISLATIVE COMMITTEE.

This report related to the bill for the appointment of Board of Medical Examiners, which was defeated by the last Legislature. The report showed that the bill was defeated by the members of the Society themselves, and detailed the energetic efforts of the committee to secure legislative protection for the medical profession.

Dr. E. E. Montgomery moved a vote of thanks to the Legislative Committee. The motion was carried.

Some discussion ensued upon the suggestion that the committee should be continued so as to make another effort to secure legislation at the next session. Action was deferred until the time allotted for new business was reached.

Dr. J. M. Anders, of Philadelphia, read a paper entitled:

THE TREATMENT OF SUBACUTE PLEURITIS.

Dr. Anders related the histories of many cases successfully treated by himself, and also spoke of the various methods employed in the treatment of this disease. He strongly advises light gymnastics for the development of the chest. The paper was discussed at some length by Drs. J. B. Roberts and James Tyson, of Philadelphia, and Dr. Carpenter.

Dr. Wm. F. Waugh then read his paper on

TYPHOID FEVER,

This being the third paper on the subject which Dr. Waugh has read before the Society. It embraced a large number of cases successfully treated.

Under the head of New Business, Dr. W. B. Ulrich, of Delaware, presented a resolution authorizing the appointment of a committee of seven, to continue the effort to have the Legislature pass a bill for the appointment of a board of Medical Examiners, and appropriating $200 for the expenses of the said committee during the year.

The resolution was adopted.

Drs. Early, Richards and Cleaver, who had been appointed to audit the report of the Treasurer, found it correct.

Dr. Hiram Corson, of Conshohocken, then presented the following preamble and resolution:

"In view of the fact that insanity seems to be on the increase in a ratio greater than the ratio of increase of population, and that just about one-half of the thousands of insane in our hospitals are females, it appears to me that it is desirable to have both sexes represented in our Board of Public Charities, and also in our Boards of Trustees of Hospitals for the care and treatment of our insane. And in the presence of the fact that the zealous, unaided efforts of a single woman—the well-known and greatly beloved Dorothea Dix—has had more effect in improving the condition of the insane in our State, and indeed in the whole country, than can be claimed of any one of us, therefore,

"*Resolved*, That a committee be appointed by the President of this Society, to appeal to His Excellency, the Governor, to fill the first vacancy which shall occur in the Board of Public Charities by the appointment of an enlightened and philanthropic woman."

The presentation of Dr. Corson's resolution and preamble, provoked some discussion.

Dr. Ulrich, of Delaware, heartily endorsed its language and paid a high tribute to women.

Dr. Bishop, of Harrisburg, suggested that the Society approach the subject with some care. He was in favor of the resolution, but the preamble, if adopted, would mean an endorsement of its language, which, however, he was not prepared to accept because he did not believe the ratio claimed was justified by facts. It was explained that the preamble was simply intended to represent Dr. Corson's personal views on the subject, and the resolution was then adopted, minus the preamble.

Afternoon Session—2 *P. M.*

The first order of business was the

REPORT OF THE COMMITTEE ON NOMINATIONS.

The Committee reported that they had unanimously elected Dr. S. L. Kurtz, of Reading, to the position of President. The announcement was warmly greeted. The remainder of the officers were elected as follows:

First Vice President, Dr. John B. Roberts, of Philadelphia; Second Vice President, Dr. H. H. Whitcomb, Norristown; Third Vice President, Dr. I. C. Gable, York; Secretary, Dr. Wm. B. Atkinson, Philadelphia; Assistant Secretary, Dr. Charles W. Dulles, Philadelphia; Treasurer, Dr. George B. Dumire, Philadelphia.

Delegates to the American Medical Association, Drs. A. M. Miller, Lancaster; H. O. Whitman, Dauphin; J. C. Biddle, Schuylkill; O. J. Stephens, Bradford; E. E. Montgomery, Philadelphia; T. M. Livingstone, Columbia; M. A. Rhoads and Henry Landis, Reading; A. B. Brumbaugh, Huntingdon; W. B. Ulrich, Delaware; W. F. Stewart, Wilkesbarre; J. J. Finnerty, Erie; H. D. Gardner, Lackawanna; J. M. Baldy, Philadelphia; R. G. McCormick, Williamsport; J. N. Richards, Bucks; Jacob Price, West Chester; A. A. Woods, Erie; J. C. Cort, Butler; Dr. Nutt, Williamsport; Hiram Corson, Montgomery; W. Murray Weidman, Berks; A. F. Bronson, Schuylkill.

Delegates to State Societies: Drs. J. W. Richards and W. L. Esters, to New Jersey; Dr. Taylor, of Wilkesbarre, to New York; Drs. M. G. Motter and T. C. Detweiler, to Maryland; Dr. M. L. Herr, of Lancaster, to the International Conference at Rome.

Dr. Thomas J. Mays then read the paper entitled:

THE CONTAGION THEORY AND TREATMENT OF CONSUMPTION.

(See Reporter, June 6, 1891.)

This was followed by a paper read by Dr. Hugh Hamilton, of Harrisburg, entitled:

THE PHYSIOLOGICAL BEHAVIOR OF KOCH'S REMEDY.

Then followed a discussion of the subject of consumption which was to have been opened by Dr. Traill Green, of Easton. This gentleman, however, being absent, the discussion was opened by Dr. Charles W Dulles, of Philadelphia.

Dr. Dulles said that it was over 200 years since Sir Thomas Brown, in his admirable work, which every physician can peruse with advantage, spoke of the curability of consumption, and in a letter to a friend cited a severe case which had entirely recovered. Dr. Dulles went on by briefly touching upon the works and experiences of various medical writers from the science's very earliest history, all showing that even at those times the possibility of the cure for consumption was recognized. To be sure, the death rate from consumption is still enormous, about 60,000 deaths occurring yearly from this disease in British countries alone. The idea that consumption is incurable is very deeply rooted in the minds of the public. This belief is not new, yet consumption has been cured even during the time of Hypocrates, who refused to regard the disease as necessarily fatal. All through the history of medicine we find cases reported in which this dread disease has been cured. Hildanus tells of a most severe case, resulting in recovery.

Christian Bennett, who was born in 1617, was himself affected, and his work in which he describes his own cure, is well worth reading. This writer said that it was well to continue the curative means for some time after an apparent cure. The late Dr. George B. Wood claimed that consumption was often cured, or at least ended in complete recovery, while the cases of Dr. Joseph Parrish, and Bowditch, are familiar to all the profession. Dr. Dulles said he doubted not but that many of his hearers could report cases illustrating the curability of consumption from their practices. He said that he had at present several patients who were entirely free from cough and walking about well, who had unmistakably come to him as consumptives. The speaker then proceeded to cite several illustrative cases.

Dr. Dulles laid great stress upon the importance of properly conducted institutions for the treatment of the disease. While many patients may be well treated at home, they would surely do better in a properly conducted hospital where every facility for proper treatment would be at hand. He also called the Society's attention to the fact that such a hospital had been recently established in Philadelphia, called the Rush Hospital, and he hoped that this hospital would prove to be a more lasting and suitable memorial to the late Dr. Benjamin Rush, than monuments in bronze or marble.

Dr. W. T. Bishop continued the discussion by saying that while he had great admiration and profound respect for investigators, yet in his own mind he classed them with pharmacists. Both, in a large measure, do their work in the laboratory. After all, the treatment of consumption must be a rational treatment, in spite of surroundings and and whether the disease be produced by a bacillus or not. Study and experience will surely show us still more, and in destroying one scientific idol we may find a new point

of value in the treatment of the disease. At present he believed that too much was claimed for new remedies, and also that too much was claimed for the disease.

Dr. Bishop agreed with Dr. Mays's assertion that consumption was neither infectious nor contagious. The immunity gained by inoculation of man or animal is still disputed, and in Dr. Bishop's mind, has yet to be proved. The finding of a single tubercle bacillus in any one of these cases destroys the entire theory.

Regarding specifics, whether for consumption or any other disease, he does not believe in their existence. The enthusiastic investigator claims far too much, and wastes much time and energy in a search for something which does not exist. They seek to rob the grave of its lawful victim. The physician can at best only direct, it remains for the patient to accomplish the rest, and so long as this is true there will be no specifics. The apparent results of delusive tables would be greatly modified if compared with family histories and surrounding circumstances, and if all these points were clearly elucidated many would change their opinion.

Dr. Lewis H. Taylor said that if he were compelled to believe all he had recently read and heard regarding the contagiousness of consumption his life would be surely very miserable. A few weeks since, he had the pleasure of hearing the reading of a very valuable paper on the subject, in which it was claimed insomuch as molasses candy might be handled by tuberculous subjects it could also become infected, and it was therefore dangerous to give it to children. Again, insomuch as oyster openers might be tuberculous, raw oysters are dangerous; likewise milk, also meat. You are in mortal danger in any public conveyance; in fact it is a real wonder that with all these menaces to human life the human race still exists! Surely in such theories there is much absurdity.

We are, however, longing for light upon this dark subject, and we shall ever strive to find it. If we can dispel from the minds of over fearful subjects, the useless fears of continual menace, as well as the theory of incurability, we shall do well; while on the other hand, equal good can be accomplished by teaching the reckless the possibilities of evil which their rashness is likely to incur.

Suitable institutes and hygienic surroundings are, of course, of inestimable value, but unfortunately are not obtainable for all classes. In such cases what shall we do? We shall do as best we can, of course; we will remedy the unhygienic condition of the surroundings as far as possible, and we will ever seek to inspire our patients with that most important factor pertaining to subsequent recovery, *hope*. Let them know that they are not necessarily doomed to an early death, but that with care an ultimate recovery is very possible.

While rushing ever onwards in our search for knowledge, it is well to also hold fast to what we do know. Were it possible to sift the good, and only the good, from the great mass of treatments, theories, and remedies that have been reported to the profession, a great good might be done, and we might justly hope for great things.

Dr. L. F. Flick then said, in continuing the discussion, that for many years he had taken great interest in the subject of consumption, and had done considerable original work. At this meeting theories had been advanced that he felt called upon to challenge. He claimed that many had very erroneous ideas regarding the primary and fundamental truths concerning consumption. Many think because it is not contagious in the sense that small-pox is contagious, it is therefore not contagious at all. Even the advocators of the contagion theory do not claim this. On the one hand small-pox is a quickly contagious disease; on the other hand consumption is a slowly contagious disease. Again, the contagiousness of tuberculosis is confined within certain limited environments, namely, pus or sputa, and it cannot get about except by pus or sputa. The idea that our lives are in constant danger may be absurd without the fact of the contagiousness of tuberculosis being denied. Consumptives may indeed expectorate sputa laden with bacilli in the street with but very little possibility of any contagion arising therefrom. The bacilli do not live forever, and the sputa may either be washed away or trodden into the earth.

Dr. Flick said that his own clinical experience had taught him that the disease only showed its contagiousness in cases of prolonged contact, such as exist when nursing a patient during the last stages of the disease. As a point illustrating the non-contagiousness of tuberculosis Dr. Mays claimed that the tuberculosis caused in animals by inoculation was not the same as that occurring in man. Clinical evidence, however, is of greater value than experimental, and it has been clinically proved beyond all doubt that tuberculosis is contagious. He then cited a series of cases coming under his own obser-

vation in which the inmates of certain houses in a given locality, were one after another attacked with the disease. In the houses observed the deaths from consumption all occurred in 20 per cent, while in 80 per cent of these houses the disease did not occur. Scrapings from the walls of such infected houses have been innoculated into animals and have caused tuberculosis. It has repeatedly been proved that prisoners placed in cells previously inhabited by consumptives, will themselves develop the disease. The disease when once introduced into a locality becomes endemic.

It is a well-known fact that certain Indian tribes which have been infected with the disease have been completely exterminated by its ravages, while other tribes in which the disease has not been introduced remain entirely free from it.

Regarding the value of the prophylactic measures that have been recently introduced in Europe for the prevention of tuberculosis, in Italy alone, where the disease has been indeed a scourge, the death rate from consumption has been reduced seventy-five per cent. since the rigid enforcement of these measures, and at present in the southern part of Italy, when at one time not long since, consumption raged the worst, the death rate from this disease is now as low as $\frac{2}{10}$ per cent., or practically nil.

"Regarding specifics, I not only believe in them, but use them with the best possible results. My own treatment consists of inunctions of a solution of iodoform in olive oil, together with larger doses of the drug internally. By this treatment I have cured a large number of cases. The gain in weight has been from six to twenty pounds, and the cough and other symptoms have disappeared. Of course I do not pretend to claim any infallibility for this treatment. The case may be too far advanced or so complicated as not to be more than benefited by this treatment."

That the treatment is of great value you will acknowledge when I tell you that my present results are from 50 per cent to 75 per cent better than they were prior to my using this method of treatment.

Dr. Ulrich, of Delaware, after telling an amusing anecdote regarding the infectiousness or contagiousness of disease, said, that after forty-five years' experience with consumption in his practice he could come to no other conclusion but that the disease was contagious. He had noticed this particularly in married couples, where the husband had consumption the wife was almost sure to develop the disease, and, indeed, frequently succumbed before the husband. The reverse was, however, seldom the case. What the means of propagation were he did not know, but that it was propagated could not be denied. Dr. Ulrich regarded poverty as a great source of consumption, due possibly to the bad hygienic surroundings of our poorer quarters.

Dr. Mays, in closing the discussion, expressed his pleasure in seeing such a general interest manifested in this important subject of pulmonary consumption; but would have to take exception to Dr. Flick's statement that while this disease was contagious it was not so in the same sense as are small-pox or measles. If it is contagious then it becomes a question of exposure, whether there may be a difference in the length of the incubation period or not. In the case of small-pox and measles those who are most exposed to the contagion are more liable than those who are not, but if it is true, as the speaker has shown, that those who are exposed to the bacilli are not more liable than those who are not, the plea of contagion, so far as consumption is concerned, must fall to the ground.

Dr. Flick's home infection theory rests on equally false premises. It shows a coincidence, and nothing else. Dr. Formad said, in discussing Dr. Flick's paper, some time ago, before the Philadelphia County Medical Society, "Who knows that affections which are universally regarded as being non-contagious do not show a similar relationship?" Probably if Dr. Flick had investigated the localities in which the abortions and miscarriages of the fifth ward occurred, he might have found that these were confined to certain houses. Dr. F. P. Henry, in discussing the same paper, said: "Sailors are very subject to syphilis, and they live chiefly at sea, therefore, from Dr. Flick's premises, we would be justified in concluding that the syphilitic poison was lurking in the fabrics of ships, and not on land where the disease is contracted.

In regard to the statistics of Naples, which Dr. Flick says show such a marked diminution in the death rate of consumption, in consequence of the rigorous measures of isolation which were enforced in that kingdom from 1782 to 1860, he would say that he has known a number of authorities who have thought and written on this subject, but none who take such a distorted view of it as is done by Dr. Flick. By what means does he arrive at this conclusion?

By quoting the statistics of 1887, which

show that Naples had a low death rate from consumption during that year. But does he know that the death rate was the same in 1860, when these measures went out of force, as it was in 1887? If he had referred to the speaker's paper on the subject, he would have found that Dr. de Renzi, whom Dr. Flick quotes so frequently, "Marvels greatly (in 1863) that the City of Naples is fully as much liable to consumption, as either London or Paris, though the salutary condition of the climate should render it far less common," and that Drs. Spatuzzi and Somma, who have paid great attention to the mortuary returns in Naples, about 1860, affirm that one-sixth or one-seventh of the whole mortality was due to consumption; a mortality which compares very unfavorably with countries where isolation of these poor victims had never been dreamed of.

After the conclusion of Dr. May's remarks the session adjourned for the day. Later in the afternoon the visitors were taken over the gravity railroad to the summit of Mount Penn, where some time was spent in the tower, 1200 feet above the sea. The time was well chosen, the air cool, and the sky clear, so that the magnificent view, embracing six counties, and the Schuylkill Valley, was unobstructed.

In the evening the visiting physicians were entertained at a reception, given by the Mayor of Reading, and at another given by Ex-Congressman Hon. Daniel Ermentrout, at his residence.

During the afternoon the exhibitors presented Dr. Howard Reeser with a complete case of obstetrical and emergency instruments, as a token of their appreciation of his disinterested labors on their behalf. The pharmaceutical firms contributed to this gift with a large collection of valuable drugs.

Third Day—Morning Session.

The third day's proceedings opened with the annual

ADDRESS ON SURGERY,

By Dr. O. H. Allis, of Philadelphia. Dr. Allis gave his paper the title of *Problem's in Surgery*, and discussed at length the subject of amputations. He is not in favor of amputation unless it become absolutely necessary. No man is so poor that he cannot be made poorer, and physicians should not be in haste to take a limb from a man. In these days of antiseptic surgery, a crushed limb can be treated in such a manner, that even if amputation becomes necessary, it can, at least, be deferred for a few days, until the patient has recovered from the shock of the accident. The speaker illustrated with the aid of charts the methods of amputating the foot. If an amputation had to be performed, it should be the chief aim of the surgeon to give his patient a good stump.

Fractures and abscesses were then referred to and suggestions made as to their proper treatment by the speaker.

The discussion of this paper was opened by Dr. Packard, of Philadelphia, who said that he favored prompt amputation when any is necessary, but allowing as much of the limb to remain as possible.

Dr. Mordicai Price, of Philadelphia, who suffered an amputation of the right leg in 1863, said that he could carry as heavy a rifle, and do as much climbing as any hunter in West Virginia. He could not understand why in some amputations an unsightly stump was allowed to remain, and that he would consider the surgeon who left more than five inches of stump below the knee, one worthy of prosecution.

The discussion was continued by Drs. Flick, Brumbaugh, Bishop, and the President, Dr. Craig.

Dr. E. E. Montgomery then read a paper entitled:

CONDITIONS REQUIRING ABDOMINAL SECTION IN PARTURITION.

In this paper Dr. Montgomery gave a brief outline of the cases operated upon by him in the Philadelphia Hospital, drawing special attention to the various indications for abdominal section in parturition.

In the discussion which followed, Dr. Duffy, of Pittsburg, endorsed Dr. Montgomery's views. The discussion was continued by Drs. Price and DaCosta, of Philadelphia.

The two following papers on the programme, "Insanity following Operations in General Surgery," by Dr. Joseph Leidy, Jr., of Philadelphia, and "Hare Lip," by Dr. DeForrest Willard, of Philadelphia, were omitted, owing to the absence of these gentlemen.

The next paper read, was one by Dr. Edward Jackson, of Philadelphia, entitled:

WHAT TO DO FOR INSIPIENT CATARACT.

Dr. Jackson, while giving various means by which relief could be approved, spoke of the bad effects the blacksmith, puddling and glass-blowing trades have upon the eyes, and the great relief afforded by dark

glasses to persons whose eyes are exposed to great heat and brilliant light.

The paper was discussed by Drs. Thomas, Barr, and Taylor. The

ADDRESS ON OPHTHALMOLOGY

was then delivered by Dr. J. A. Lippincott, of Pittsburg. The speaker dwelt principally on the subject of trachoma, which he said, prevailed to a great extent in orphan asylums, public institutions, and among imigrants.

A number of proposed amendments to the constitution and by-laws were then proposed, after which the session adjourned.

Afternoon Session.

Dr. Milton Duff, of Pittsburg, opened the session by the annual

ADDRESS ON OBSTETRICS

which embraced an interesting history of, and the present standing of, our knowledge of this subject. He was followed by Dr. S. Solis-Cohen, of Philadelphia, who read a paper entitled:

NEWSPAPERS AND PATENT MEDICINES.

He said: "The subject is a delicate one, and when agitated the parties who advance any opinion against the pernicious evil, are accused of having a personal interest in some similar scheme, or that they desire to choke off all competition.

"There exists in every community a palpable and glaring evil, which reaches high and low, rich and poor. We desire to ask the publishers of the newspapers whether they are willing, in the sight of God, to continue to lend their aid to this fearful evil, the advertising of patent medicines. The miserable newspaper that goes to the poor, and the higher class of reviews and magazines which cater to the rich, both contain column after column of advertisements, testimonials, and certificates which are fraudulent and lying upon their faces.

"No man, be he editor or journalist, believes that a clothing store that only possesses one suit of clothes can perfectly fit anyone. Any physican who advances one effort to produce an abortion, is ignorant of the first principle of his art. In the newspapers we find column after column of advertisements promising to cure diseases of the blood, skin, and lungs if the patient will only swallow these money-making remedies. Men who put forth these advertisements, use the newspapers as a net to catch the poor, deluded creatures who eagerly endeavor to cure themselves by placing faith in these advertisements, written in the blood of thousands who have already become their victims.

"Have newspaper publishers a legal right to publish such advertisements? The answer unfortunately must be, that there is no Legislature to prevent it. But we all deny their moral right. They say that they do not guarantee the nostrums which they advertise. But the editor does guarantee, and is personally responsible for all editorials, and therefore he carefully considers and balances all which goes into the columns of his paper. Why not consider the health and happiness of the people to whom he caters? They say that one is not compelled to buy them, but this is only a secondary consideration, and the use of these quack nostrums is, in a large measure, due to the promiscuous advertising received from the newspapers. Our postal authorities forbid all newspapers, containing the announcement of any lottery, the privilege of the mails, yet, where is there a lottery half go bad as these vile mixtures which bear the name of patent medicines? These mixtures cause patients to lose valuable time in their desire to procure health, and often result in causing death. Many a child has been soothed to death by the use of soothing syrup; many a drunkard has been driven to death by the use of so-called substitutes for whiskey, and many a morphine eater has been killed by the use of substitutes more dangerous than morphine itself. We all have among us, either as patients or friends, editors and newspaper men, and let us go to them, not indignantly, but calmly and in a friendly manner, and put the subject before them. If I were an editor and should insert such an advertisement, I would consider every dollar that I received from such a source as so much "blood money," and as if stamped with the skull and cross bones."

The discussion of this paper was opened by Dr. F. W. Muhlenberg, of Reading, who said that the speaker had omitted to state that religious journals and orators were guilty of the same offence.

Dr. J. L. Zeigler, of Mount Joy, stated that before the discussion went any further he wished to say that it was a case of "Physician Heal Thyself;" and that before the doctors raise a cry against patent medicines they must see that medical colleges turn out better material, and not allow certificates to be given by so-called colleges, which are the worst frauds in the

country. The legislature is perhaps somewhat responsible for this state of affairs, by not acceding to the demand for a Board of Examiners, and thus allowing one of the most glaring frauds which has ever been perpetrated upon the people.

Dr. C. R. Early, of Ridgeway, read a paper on

CATARRH.

The paper dealt chiefly with the therapeusis of catarrh, and many interesting cases were cited.

The last speaker was Dr. John Aulde, of Philadelphia, who read a paper on the

PHARMACOLOGY AND THERAPEUTICS OF ENPHORBIA PILULIFERA.

The speaker claimed many new and interesting properties for the drug, and gave brief histories of a number of cases in which it had been successfully employed.

AMENDMENTS.

Dr. Solis-Cohen, of Philadelphia, moved that the chairman of the Committee on Publication receive the same salary as before, viz., $150, which was adopted.

Dr. Solis-Cohen also offered an amendment to the by-laws and constitution, to the effect that the record of each member include the name of the college where he studied, and the date of graduation. Carried.

The following resolution, offered by Dr. J. A. Lippincott, of Pittsburg, was unanimously adopted:

"*Resolved*, That a committee be appointed on 'Contagious Ophthalmology in Public Institutions,' whose duty shall be to communicate with those who exercise supervision or control over orphan asylums, orphan schools, reform schools, and kindred institutions, with a view of ascertaining what means, if any, are exerted to prevent the introduction and spread of the various forms of contagious eye disease among the inmates. The committee shall also devise such means, as shall in their opinion seem best calculated to lessen the evils which flow from these diseases."

There being no further new business the day's session closed.

Later in the afternoon the visiting physicians paid a visit to St. Joseph's Hospital, where a lunch was served; and at 6 P. M. started on a trip over the Neversink Mountain Railway, stopping at the Highland House and Klapperthal, and enjoying a supper, dance, and music.

FOURTH DAY.

The fourth day's session was merely a formal one and occupied but a few hours. The following list of censors was elected:

1*st District.*—Drs. S. P. Bartleson, Delaware; J. W. Walk, Philadelphia; James Fulton, Chester.

2*nd District.*—Drs. J. B. Walter, Bucks; Traill Green, Northampton; W. B. Erdman, Lehigh.

3*rd District.*—Drs. Hiram Corson, Montgomery; W. Murray Weidman, Berks; A. F. Bronson, Schuylkill.

4*th District.*—Drs. J. M. Deaven, Lancaster; H. O. Orris, Perry; H. L. Orth, Dauphin; A. M. Smith, Snyder.

5*th District.*—Drs. S. P. Ziegler, Cumberland; J. W. C. O'Neil, Adams; D. K. Gotwald, York; J. Montgomery, Franklin.

6*th District.*—Drs. A. B. Brumbaugh, Huntingdon; Crawford Irwin, Blair; John Lowman, Cambria; H. M. Lichte, Somerset.

7*th District.*—Drs. J. O. Robertson, Westmoreland; J. S. Hackney, Fayette; William Anderson, Indiana; J. A. Armstrong, Armstrong.

8*th District.*—Drs. James McCaen, Allegheny; Jesse L. Scott, Washington; W. S. Throckmorton, Greene.

9*th District.*—Drs. S. D. Bell, Butler; E. Griswald, Mercer; D. S. Margins, Beaver; J. A. Richey, Venango; J. Cresswell, Clarion.

10*th District.*—Drs. A. A. Woods, Erie; W. V. Hazeltine, Warren; R. B. Brown, Jefferson; A. M. Straight, McKean.

11*th District.*—Drs. D. A. Hogue, Clearfield; G. T. Harris, Centre; P. H. Detweiler, Lycoming.

12*th District.*—Drs. S. C. Newbaker, Montour; E. R. Meyer, Luzerne; J. H. Vastine, Columbia, L. M. Gates Lackawanna.

13*th District.*—Drs. J. W. Lyman, Bradford; S. Birdsall, Susquehanna.

Then followed the inauguration of the President-elect, Dr. Kurtz. After a vote of thanks being tendered the retiring officers, and the disposal of unfinished business, Dr. Kurtz, the President-elect, adjourned the forty-first annual meeting of the State Medical Society, of Pennsylvania, until the second Tuesday in June, 1892, at Harrisburg.

The State Society has at present a membership of 2,172. At this meeting 300 physicians registered.

The committee of arrangements to whom the success of the meeting was so largely due, included Drs. Samuel L. Kurtz, Chair-

man, James Y. Shearer, C. W. Bachman, H. S. Reeser, M. A. Rhoads, Samuel C. Ermentrout, and A. S. Raudenbush, all of Reading, Pa.

SELECTED FORMULÆ.

IRRITABLE BLADDER.

℞

Potassium citrate	ʒ iv.
Fluid ext. triticum repens	
Tinct. of hyoscyamus	aa ʒ j.
Fluid ext. of buchu	ʒ ss.
Water, sufficient to make	ʒ iij.

M. Sig. One teaspoonful in a wineglassful of water, three or four times daily.

—*Med. Summary.*

TREATMENT OF DYSENTERY.

Minorbi, in *L'Union Medicale*, describes a method of treatment which he has followed in twenty-three cases of dysentery. In one case a cure was obtained in a very few days. The treatment consisted in the insertion into the rectum of suppositories made in the following manner:

℞

Naphthalin	ʒ ijss.
Cocoa butter	ʒ ijss.

Where there is ulceration or any other condition which tends to make the use of a suppository painful or dangerous, he has recourse to the following injection:

℞

Naphthalin	grs. lxxv.
Olive oil	ʒ vj.

At the beginning of an attack, when there is a good deal of tenesmus, the injections should be given every half hour, but ordinarily it is sufficient to repeat them three or four times in the twenty-four hours. The advantage of this method is that it does not cause constipation, which opium is apt to produce.

WHOOPING-COUGH.

(Germain Sée in *Jour. de Médecine*):

℞

Powdered belladonna root	gr. 1-5.
Dover's powder	gr. ss.
Sublimed sulphur	gr. iv.
White sugar	gr. x.

M. Sig: Take in one dose from two to ten times a day, according to age of patient and effect produced.

—*Am. Pract.*

"ONE MINUTE LIGHTNING DROPS."

℞

Ol. sinapis	gtt. v.
Chloroform	gtt. x.
Spts. terebinth	gtt. iij.
Spts. vini. rect	ʒ ss.

—*Pharmaceutical Era.*

FOR INTERNAL HÆMORRHOIDS.

℞

Chrysarobin	grs. xv.
Iodoform	grs. v.
Extract of belladonna	grs. viij.
Cocoa butter	ʒ vj.

Of this are made ten suppositories, and one suppository ought to be inserted into the rectum each day. After five or six hours the pain and the tumor diminish. The treatment may continue for several months without harm.

INTESTINAL FLATUS.

Many young children are irritable, and cry because they have intestinal flatus. Instead of using opiates which are the basis of most of the soothing syrups, Prof. Bartholow gives the following as a valuable remedy:

℞

Misturæ assafœtidæ	f ʒj.
Sodii bromid.,	gr iij-v.

M. This is a dose for a child from one to four months old.

—*College and Clin. Record.*

PURGATIVE PILLS.

℞

Aloes	15 grains.
Resin of scammony	7 "
Resin of jalap	7 "
Calomel	7 "
Extract of belladonna	3 "
Extract of stramonium	3 "

Make into twenty-five pills and give one to two a day.

COUGH MIXTURE.

The following is said by the *College and Clinical Record* to be Dr. E. G. Janeway's favorite cough mixture:

℞

Syrup. tolu	
Syrup. pruni virginian	
Tinct. Hyoscyami	
Spirit. ætheris comp	
Aquæ	aa ʒj.

M. Sig.—Dose a teaspoonful.

TREATMENT OF GONORRHŒA BY BICARBONATE OF SODA.

According to the *Journal de Médecine de Paris*, Casselan during the past four years has employed a solution of bicarbonate of soda in the strength of 1:100 in the treatment of gonorrhœa. He has treated thirty-three cases and obtained thirty-three cures in from two to three weeks by the employment of injections of the solution named. He bases his treatment on the belief that the virulence of the disease is in direct proportion to the acidity of the secretions.

DIPHTHERIA.

Andeer recommends the application every hour or two, night and day, of the following:

℞ Resorcin.....gr. xlviij.
Glycerine.....f ʒ i.
M.

A spray of a five per cent. solution of the drug should be used in the room and the following administered internally:

℞ Resorcin.....gr. x.
Syrup terebinth..... f ʒ i.
S.—A teaspoonful every three or four hours.

—*Centralblatt f. d. Gesammte Therapie.*

INHALATION FOR WHOOPING-COUGH.

Beall recommends the following formula:

℞ Thymol.....gr. xx.
Acid carbolic, }
Ol. sassafras, |
Ol. eucalypti, } .....aa f ʒi j.
Reis liq idæ, |
Ol. terebinthinæ, }
Ætheris,.....f ʒ iv.
Alcoholis,..... .....q. s., ad. f ʒ iij. M.

S. Put about thirty drops upon a pad of such size as to be conveniently hung around the child's neck, renewing the application every two or three hours.

—*Daniel's Med. Jour.*

SUBACUTE OR CHRONIC DIARRHŒA.

The following is recommended in the *Southern Med. Record:*

℞ Acaciæ pulv.....ʒ iss.
Creasoti (beechwood).....gtt. xxxii.
Aquæ.....ʒ iv.

Fiat emuls. Sig. A teaspoonful in water (for adults) every 4 to 6 hours.

THE TREATMENT OF TYPHOID FEVER.

Smakovsky, during the space of two and a half years has treated 700 cases of typhoid fever in the following manner:

℞ Calomel.....½ grain.
Sugar.....4 grains.

This to be made into ten powders and one powder given each hour until the evacuation from the bowels becomes copious and soft. The patient is also given a gargle, composed of a solution of chlorate of potash, to prevent mercurial stomatitis. If there are evidences of feebleness of the heart, the calomel is stopped and small doses of the infusion of digitalis are administered. After the calomel has produced its antiseptic and alterative influence the diarrhœa, if it has become excessive, may be controlled by the use of the following powders:

℞ Subnitrate of bismuth.....2 grains.
Naphthalin.....½ grain.
Sulphate of quinine.....1 grain.

One of these powders to be given four times a day.

For the cough Smakovsky recommends:

℞ Aqua ammonia.....1 drachm.
Tincture of eucalyptus.....1 ounce.
Essence of peppermint.....10 drops.

Ten drops to be given every two hours.

This prescription is also of advantage in acting as a disinfectant of the mouth. The Russian investigator just named is convinced that the mortality of typhoid fever under such treatment is very much lessened.

—*L'Union Médicale.*

SOOTHING SYRUP FOR CHILDREN.

We do not recommend any narcotic soothing syrup, although such are much used; the employment of opiates in these preparations is unsafe, and should be discouraged as far as possible. The following is effectual and perfectly safe:

℞ Treacle.....1 lb.
Distilled water.....1½ pints.
Stronger tincture of ginger.....½ fl oz.
Oil of cloves.....20 min.
Oil of sassafras.....30 "
Oil of caraway.....5 "
Oil of aniseed.....10 "
Rectified spirit.....5 fl ozs.

Dissolve the oils in the spirit, then add the treacle with the water, and mix. Dose, from half to one teaspoonful.

—*Era.*

ACUTE URETHRITIS.

Professor J. William White, of the University of Pennsylvania, recommends the following mixture, in capsules. In about two-thirds of his cases the discharge ceased within a week. In the majority it was necessary also to use an injection, and for this he recommends two to ten grains of sulpho-carbolate of zinc in a ten to fifteen per cent. solution of peroxide of hydrogen:

℞ Salol.....3½ grains.
Oleoresin of cubebs.....5 grains.
Balsam of copabia (Para).....10 grains.
Pepsin.....1 grain.

VOMITING OF PREGNANCY.

Cocain with Acetanilid is recommended in the vomiting of pregnancy, also in acute gastralgia, in this proportion:

℞ Cocain. mur.....gr. iii.
Acetanilid.....ʒ ss.
Aquæ.....ʒ v.

Sig. A teaspoonful hourly.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE TABLE OF CONTENTS.

In response to what we believe is the general wish of our readers, the table of contents is permanently restored to the title page.

LEADING ARTICLE.

The lack of attention given by the pædiatrist as well as the general practitioner to the subject of infantile malaria, is surprising. Both, in meeting intermitting febrile symptoms in very young children and infants, are prone to advance any other diagnosis rather than that of malaria. Recent statistics show that intermittent fevers occur with greater frequency in the early years of life, than at any other period, and that the ages showing the greatest susceptibility to malarial infection are the first and second years.

The chief reason for the failure to recognize intermittent fevers in infants, is owing to their atypical course, which in comparison with the symptomatic picture of intermittent fever in adults, seems an almost totally different disease. It is for this reason that, in all probability, even eminent pædiatrists, failing to recognize the real trouble, have treated the manifestations of infantile malaria as other affections.

In infantile malaria the initial chill is absent, perspiration is seldom observed, and the intermissions between the febrile attacks are usually not clearly defined. In the majority of cases the temperature between the attacks will be ½ to 1½° C. above normal; and in this respect the disease resembles a remittent rather than an intermittent fever.

The infantile organism reacts so strongly to any infectious febrile disease, that it is not long, in cases of malaria, before the digestive and respiratory systems become involved. The child rapidly falls away, the facial color becomes bad, and anæmia is rapidly established. Unless the case occurs in a well-recognized malarial region, the attending physician is almost certain to make a wrong diagnosis. The attending complications will seem to justify a diagnosis of gastric or intestinal catarrh, or even a mild form of typhoid fever, bronchial catarrh

or possibly even phthisis. If the disease occurs during the teething period it is very frequently called "dentition fever." If, in such cases, after having exhausted almost every therapeutic means, the physician tries quinine, he will be greatly surprised at the rapid recovery of his little patient.

Light cases of infantile malaria often recover spontaneously, and for this reason escape notice; indeed, even in the severer forms, a change of air or climate will frequently be productive of excellent results.

In this article, necessary brevity forbids our giving a detailed account of the symptomatology of the various forms of infantile malaria. The subject is one so extensive, and of such interest, as to be a worthy the me for a lengthy monograph. We would, however, state that the greatest stumbling block in the physical diagnosis of these cases has been, the peculiarity and atypical nature of the temperature curves, and the relative condition of spleen and skin. The regular rise of temperature, coupled with restlessness and various nervous symptoms is of great diagnostic value. If such symptoms are present in a child in a district where malaria is known to exist, even although slightly, a diagnosis may safely be advanced. Large doses of quinine—0.5 to 0.8 gramme, *pro die*, according to the age of the child—may be given with impunity, and are productive of excellent results. In such parts of the country in which malaria is unknown, to adults, at least, cases of intermittent fever in children can frequently be shown to be of a malarial nature, apart from their tendency to yield quickly to quinine.

It is not long ago since Laveran and Marchiafava-Celli discovered the *hæmoplasmodium malariæ* to be the germ of malaria. Since then, Dr. Carl Hochsinger, of Vienna, who has made the subject of infantile malaria a special study, has been able to trace this plasmodium in the blood of a number of cases of intermittent fevers in children, when otherwise, from the locality, such a diagnosis would seem unwarrantable. Dr. Hochsinger contributes a most interesting article on the subject in the *Wiener Medizinische Presse*, April 26, 1891, in which he states that during the past year he has found these germs in every one of twenty-four cases of infantile intermittent fever, which have come under his observation. The youngest child in which these germs of malaria were found was only three months old.

In searching for the plasmodium in the blood, Dr. Hochsinger makes use of a solution of methylen-blue and eosin. Taking 100 grammes of a strong, but not concentrated, aqueous solution of methylen-blue, he adds to this a few drops of absolute alcohol, and then ½ gramme of soluble eosin. The mixture is then bottled and sterilized by boiling and will keep for an indefinite length of time. A small quantity of this solution is poured into a shallow dish, and the slides, containing a dry preparation of the blood, are allowed to float in the solution for ten to fifteen minutes, then rinsed off and sealed. Under the microscope the red blood corpuscles will be found stained a deep red, the nuclei of the leucocytes a deep, dark blue, and the hæmatozœæ of malaria a delicate sky-blue.

In every case examined by Hochsinger large quantities of these plasmodia were found, varying in number, form and kind, with the intensity of the disease. In all cases and all stages of the disease, Laveran's so-called *corps segmentés* were observed. These were seen as large groups of closely packed corpuscles of protoplasm of a delicate blue color, and about as large as ⅛ to ⅕ of a red blood corpuscle. In three cases the flagelats form were found, and in one case of severe cachexic malaria, terminating fatally, well defined crescent forms were also visible. The segmented variety were present in every case, and in especially large numbers in the youngest subjects.

Examination of the blood is, therefore, of the highest importance in cases where the possibility of malarial infection in infants and young children is suspected, and also in those cases of intermittent fever in children, of an uncertain origin. The diagnostic value of such an examination is especially great, as

these plasmodia are only found in cases of malarial infection.

With the extreme susceptibility and predisposition of the infantile organism to malarial poisoning on the one hand, and the comparatively easy, and at once positive diagnostic method on the other, the practitioner should not rest content with an uncertain diagnosis in any case of infantile fever of obscure origin, without having first precluded the possibility of a malarial infection by the above simple yet unerring test.

CORRESPONDENCE.

ED. MEDICAL AND SURGICAL REPORTER.

Dear Sir:—I would like to place on record a brief note of two cases, which I have recently done, both of which are cases of abdominal tumors complicating pregnancy. I will in time make full reports of both.

On April 1st, I removed a large intraligamentous ovarion cyst from a lady from Butler Co., Pa., who was pregnant 3½ months. She has gone home, pregnancy not disturbed.

On May 23, I removed from a lady, resident of East Liverpool, O., a fibrocystic tumor, growing from the fundus of the uterus, weighing 22 pounds, with the uterus pregnant 5 months. The child was living, but died. She is in her sixth day, pulse and temperature normal. The first Porro operation in the State, outside of Philadelphia, so far as I know.

Very truly yours,

R. STANSBURY SUTTON.

419 Penn Ave., Pittsburgh.

BOOK REVIEWS.

A GUIDE TO THE CLINICAL EXAMINATION OF THE URINE. By FARRINGTON H. WHIPPLE, A. B. (Harv.) Boston, Damrell and Upham, 1891; pp. 206.

Had there been an urgent demand for any condensation of the already existing works upon urinary examination, possibly Mr. Whipple would have had an excuse for rushing into print with this volume. As it is, however, there is no reason for its existence, even were it a first-rate compilation. Moreover, the book is exceedingly insufficient, both in clearness and accuracy, and in the presentation of the more recent additions to our knowledge of urinary matters.

There can scarcely be a necessity for a systematic consideration of the entire work after such an introduction; and, in fact, sufficient illustrations may be cited from random pages to prove the above assertion. For example, in the consideration of the subject of albumen in the urine, the only tests mentioned are those by heat and acetic acid, and by nitric acid; there are no quantitative tests, not even the popular Esbach's tube. None of the newer albumen reagents are considered: picric acid, the ferrocyanide test, trichloracetic acid, Tanret's or Millard's. In the estimation of sugar the same fault may be cited—there are none of the newer tests, and those as a rule are badly put. For example, the following covers the subject of the fermentation test for sugar (excluding reference to the differential density method): "*Fermentation Test.*—By fermentation, sugar is broken up into alcohol and CO_2; therefore it is only necessary to cause fermentation in the urine, which can be done by the addition of a little yeast-cake. The CO_2 as it forms is passed through baryta water." As a guide for those who need directions, such guidance must be regarded as exceedingly meagre.

In the study of hæmaturia, the urinary symptom is used as an excuse for leading the author into an entirely irrelevant biological study of the blood with a consideration of the differences between the blood of the different animals. The author's test for iodide of potassium in the urine, which substance he recognizes by a brown ring between the layers of nitric acid and urine in the ordinary application of Heller's test for albumen, would be greatly improved, if, after freeing the iodine by any of the stronger mineral acids, some characteristic color reaction were added, as seen, for instance, in the solution of the iodine by chloroform.

The author states that when H_2S exists in the urine in conditions unassociated with disease of the urinary system it is to be regarded as a favorable symptom. Hydrothionuria is, however, a condition which is rarely recognized in the freshly passed urine, except as a phenomenon of bacterial invasion of the urinary system, or of some connection between the intestinal canal and the urinary apparatus, and in either case is exceedingly unfavorable; beyond this, as a demonstrably free substance in the urine, H_2S practically does not exist.

In the optical appearance of calcic oxalate crystals Mr. Whipple entirely forgets the very characteristic refractive property of these bodies; hence in his separation from similarly shaped crystals of phosphate he must have recourse to chemical tests. On the subject of casts he states that only in a few isolated cases have these been detected in non-albminous urine; in our experience in cases of interstitial nephritis it is quite a common occurrence to meet specimens of urine presenting typical casts, in which with the tests mentioned by Mr. Whipple, absolutely no traces of albumen can be discovered. His simile that a waxy cast "bears somewhat the same relation to a hyaline cast that a fat drop does to an abnormal blood disk" seems exceedingly indefinite and nondescriptive. He states that "pus casts may occur in the course of acute inflammatory conditions. In pyelitis and pyelonephritis the pus corpuscles are frequently agglomerated in masses which are suggestive of casts and may come from the straight tubules. They are usually of considerable size—much larger than the renal casts."

The view announced by Mr. Whipple that active hyperæmia of the kidney is identical with parenchymatous degeneration ("cloudy swelling," large white kidney) may account for his failure to notice pus casts in cases of Bright's disease that are not to be regarded as distinctly acute processes. Both these views are, however, contrary to the truth. Pus casts, casts to which pus corpuscles are intimately attached, in urines showing few free pus corpuscles, may be taken as an indication of tubular inflammation; and the pus cells possess the same significance so far as the nature of the process is concerned as do renal tubular epithelial cells. Such casts may be found in varying amounts in almost every case of catarrhal nephritis from the first to the last stage.

Such instances may serve to point out the general character of Mr. Whipple's book; almost every page is, however, open to some objection when he does not adhere strictly to the teachings of the older works upon which his book is based. The present edition cannot possibly be regarded as a success from a scientific point.

HISTORICAL SKETCH OF THE UNIVERSITY OF MARYLAND. By Eugene T. Cordell, M. D., of the class of 1868, Baltimore. Press of Isaac Friedenwald, 1891.

This octavo volume, of some two-hundred and fifty pages, contain a history of the school of medicine from the year 1807 to 1890, inclusive, together with an introductory chapter, in which are recorded events preceding the founding of the college of medicine of Maryland in 1807;—also notices of the schools of Law Arts and Sciences, and Theology, and the department of Dentistry, and a general catalogue of medical alumni. There are likewise included some twenty illustrations and portraits and about seventy memoirs.

Special emphasis is laid upon the necessity of endowing the university, especially the medical department, and the author does well when he states that in order to make the rank of medical schools in this country, of the highest standard and their graduates worthy of the title "Doctor of Medicine," it is essential that the schools be fully endowed; for the scientific requirements of modern medicine demand a large outlay which cannot always be met by the mere fees of students, fluctuating and hence uncertain as they necessarily are, and without which support, most of the medical colleges as now conducted, would cease to exist.

The book is more than a *sketch*, as the author modestly titles his work,—it is a complete record of the medical school of the Maryland University, and therefore will receive undoubtedly a cordial welcome at the hands of the many alumni of the institution.

THE DISEASES OF PERSONALITY. By Th. Ribot, Professor of Comparative and Experimental Psychology at the College of France, and Editor of the "Revue Philosophique." Authorized American Translation, Chicago. The Open Court Publishing Company, 1891.

For the student of Psychology, this small volume contains much of interest. The contents are embraced in an introductory and five chapters. The titles of the latter are: 1. Organic Disorders. 2. Emotional Disorders. 3. Disorders of the Intellect. 4. Dissolution of personality; and finally the Summary.

The author is a well-known writer on Psychological subjects, as well as editor of a periodical devoted entirely to this study, which account for the masterly manner in which the difficult subject of the present volume is handled.

FOR SOFTENING EAR-WAX.

La Clinique recommends the following:

℞ Acid. Boric.....grv.
Glycerini.....
Aquæ.....aa ad ℥j
M. Ft. sol.
Sig: Warm the solution and put 5 to 10 drops in the ear twice a day.

PERISCOPE.

THERAPEUTICS.

THE EMPLOYMENT OF GUAIAC AS A PURGE.

Murell (*Rev. Therap. Med. Chirurg.*, Paris, Jan. 15, 1891) attributes to guaiac laxative and purgative properties, believing it to be a stimulant to the liver and intestines. He has employed it with satisfactory results in several cases of biliousness and constipation. The drug was administered as a purge, in combination with honey, in doses of 60 centigrammes. This quantity was generally sufficient to produce a purgative effect. He reports a case in which the remedy produced a well-marked eruption of the arms and legs, accompanied with intense itching, but these symptoms disappeared on the suspension of the drug.

In order to avoid the disagreeable griping sensations which the medicant sometimes produces, Murell recommends a combination of the drug and extract of malt. The author believes, also, that if this preparation is triturated with cream of tartar, sugar of milk, or other inert substance, its efficacy may be observed when administered in small doses.

RADLAUER'S ANTISEPSINE.

According to the *Inter. Nat. Pharm. Gen. Anz.*, Jan. 30, 1891, this substance is a combination of iodate of zinc, zinc, and thymolic borax, brought about by treating these agents with antiseptic measures. Antisepsine produces the same antiseptic effects as iodol, thymol, boric acid, and the salts of zinc; it entirely supplements iodoform, carbolic acid and corrosive sublimate. Its advantages are as follows: 1. While it is a powerful antiseptic it does not possess toxic properties, nor are its marked effects ever of a poisonous nature. 2. It is free from bad odor, and it exercises no local irritant action. 3. It is easily soluble in absolutely clear water It is a whitish powder, its price being reasonable, more so than that of iodoform, iodol or aristol.

THE TREATMENT OF LUPUS.

H. Leboir (*Journal des Maladies Cutanées et Syphilitiques*, Jan., 1891) divides the treatment of lupus into *two* great classes: The local and the internal treatment. The first he again divides into the surgical, the medical and the mixed treatments. This last one is preferred by the author in the majority of cases.

In the surgical treatment five methods are employed, as follows: ablation, scraping, scarifications, cauterizations, and electrolysis. In the application of all these methods, local and general anæsthetics are used. With regard to the employment of germicidal and caustic agents, the latter are preferred. In general, the local medication is not regarded favorably by the author; on the contrary, the mixed treatment, chiefly made up of cauterizations and the local applications of iodoformed ether should be the base for the general treatment of lupus.

The general treatment should be looked upon as an adjuvant to the local one. That treatment may be reconstructive and specific, in the first case, cod liver oil, arsenical preparations, sulphur, and other alteratives may be administered, and in the second, iodoform, iodol, and creosote may be employed together with subcutaneous injections of iodoform. In regard to the Koch remedy, the author has formed no definite opinion, but as that agent appears to possess an elective action towards lupus, it may be employed for the present, as an element of diagnostic value.

ACTION OF ANTIPYRETICS.

The action of antipyretics may be supposed to be due to the limitation of the oxidation processes and consequent lowering of heat development, or to an increase in the heat radiation from the surface of the body. Moreover, they may have a purely local action,—*i.e.*, on the cellular tissue,—or they may influence the nerve-centres, regulating the development or radiation of heat. Messrs. Sawodowsky and Podanowsky consider that they have proved that the lowering of temperature produced by antipyrine and antifebrine is attributable exclusively to their influence upon the brain-centres regulating the temperature, which are believed to exist in the corpus striatum (*Apot. Zeit.*, February 11, p. 87). The authors cut the brain of an animal through close behind the corpus striatum and thalamus opticus, so as to isolate the organism from the heat-centres, while the connection with the respiration and vasomotor centres was retained. Although the animal so treated lived for some time, and the arterial blood-pressure and breathing remained unaltered, the body temperature fell continuously. Even injections of the most powerful pyretics, such as putrescent matter, caused not the slightest rise of temperature,

although all the other symptoms of putrescent infection were present. Equally powerless were antipyrine and antifebrine to hinder in the slightest degree the fall of temperature. The skin temperature also remained entirely unchanged, although in the case of normal animals this rises considerably after the injection of antipyretics. An apparent exception was noticed in the case of quinine hydro-bromide, but this was attributed to the known action of bromine. The conclusion drawn by the authors is that the action of quinine salts—resorcin and thallin—in lowering the temperature is dependent upon their specific influence upon the temperature regulating centres situated in the anterior part of the base of the brain.—*Pharmaceutical Journal and Transactions*, February 28, 1891.

JAMBUL IN THE TREATMENT OF DIABETES.

Among the newer drugs which have been suggested for the treatment of diabetes mellitus, the seeds of Eugenia jambolana, Lamarck, a tree of the family myrtaceæ, growing in Java, the Molucca and Phillipine Islands, and in parts of India, have been most favorably commended by several English and American writers, most notably by Scott (*British and Colonial Druggist*, 1887). The chief advantage of the drug, as expressed by these observers, was the possibility of controlling the excretion of sugar, without the necessity of restricting the diet. A careful study of the subject has recently been undertaken by Villy (*Bulletin général de Thérapeutique*, Jan. 30, 1891), whose observations throw considerable light upon the chemistry and clinical action of this drug. Although as large a dose as an ounce to an ounce and a half of the seeds has been given to the adult in twenty-four hours, no case of poisoning has been recorded; and the author finds that a rabbit may be given its own weight of the drug within twenty-four hours without disturbance of its nutrition.

Contrary to the observations of Scott, it was demonstrated that jambul favors and hastens saccharine fermentation at a temperature of 70°. The same result was noted in experiments made at the normal temperature of the human body, but the process was somewhat more slow. Judged, therefore, simply by the result of experiments outside of the body, the drug would appear to be ill-suited to the indications of the disease.

His clinical observations are interesting, and seem to show that the applicability of this drug is quite limited. As long as the ordinary diet is permitted, the use of jambul is dangerous, as favoring the persistence of polyuria and increasing the excretion of sugar and urea. In cases of moderate degree, with or without azoturia, in stout and gouty patients, jambul seems to be of value, provided that at the same time an exclusive diet is maintained. In this respect the drug does not differ from other therapeutic agents employed in this disease. Most frequently sugar disappears rapidly from the urine, but reappears almost as soon as the medication is suspended.

In grave cases, where regulation of the diet appears to be without effect, jambul, like other remedies, is of no value. The powdered seed is well borne by the stomach to the amount of 150 to 320 grains, in divided doses, in the twenty-four hours.—*Univ. Med. Mag.*

TREATMENT OF TUBERCULOUS BRONCHITIS BY HYPODERMIC INJECTIONS OF IODOFORM.

Influenced by the action of iodoform on pus globules, Dr. Gavoy announces in the *Gazette Médicale de Paris* for February 28, 1891, that in 1887 he was led to test this remedy in pill form in tubercular bronchitis, but the gastric distress and nausea caused by the administration of the remedy compelled him to substitute enemata for the internal administration in the pill form, and he has now, for various reasons, substituted for these methods the hypodermic method. He states that at the outset he employs, morning and evening, a hypodermic injection of a quarter of a syringeful of a solution of 1 part of iodoform in 100 parts of oil of sweet almonds. In very few cases, he states, is any febrile reaction produced, and the results obtained in the majority of cases are excellent. He maintains that in his use of this remedy the cough rapidly diminishes; muco-purulent expectoration, so characteristic of this specific catarrh, becomes more fluid, and finally ceases almost entirely; alteration in the character and hoarseness of the voice disappear; the lungs become more permeable to air; inspiration becomes deeper; the vesicular murmur acquires another character, and subcrepitant moist râles disappear, nocturnal sweats cease, the appetite returns, and the patient's general health improves. In fact, he states, that progressive improvement in the majority of cases indicates in the most positive manner arrest of this broncho-pulmonary catarrh of phthisis.

He states that the examination of the sputum for bacilli is not an indispensable criterion for this therapeutic process, for the presence of the bacilli can only be exceptionally located at the onset of tubercular bronchitis, and, although the bacilli may exist in small closed cavities in the lungs, they only appear in the sputum when the ulceration has communicated with the bronchi. Further, iodoform is said to have the power of liquefying the more or less solid obstruction in the alveoli. He suggests that the therapeutic action of iodoform on caries of bone and on pus globules permits of the supposition that it may exert an analogous action on yellow tubercle and during the stage of softening, a condition which might be described as a caries of the lung. Although iodoform is an active antiseptic agent, it does not appear to have any direct action on the bacilli of tuberculosis other than in modifying the character of the tissues in such a manner as to delay or prevent the reproduction of the bacilli, and in aiding the elimination of the results of tissue breaking down, and favoring the cicatrization of ulcers seated in the alveoli. He recommends in the warmest terms further tests with this remedy in this connection.—*Therap. Gaz.*

ON THE UTILIZATION OF THE FOOD IN CASES OF GASTRIC DISEASES.

Dr. C. Noorden (*Ztschr. f. Kl. Med., Bd.* xvii.) has made some experiments to determine what becomes of the food in functional gastric disorders after it has left the stomach. He selected seven patients in whom the production of hydrochloric acid had been reduced to a minimum, and in whom the food was so rapidly carried into the intestine that even if lactic acid fermentation had occurred, it could not have attained a degree sufficient to peptonize albumen in the stomach. Propepsin was formed in all of the cases in abundant quantities. These experiments demonstrate that even in cases where no pepsine or hydrochloric acid is secreted the intestine is capable of completely fulfilling the office of the stomach. The reduction of the bodily weight observed in cases of chronic gastric disease is attributed by the author to an insufficient supply of food, since the two other factors which might be held responsible for it, viz.: the formation of toxines, and the excessive decomposition of the albuminous substances in the intestines, owing to fermentation resulting from the diminished disinfectant power of the abnormal gastric juice, can be excluded. The hydrochloric acid secreted in the stomach does not exert any disinfectant properties beyond the boundaries of that organ, and has no part in intestinal disinfection. The theory of motor insufficiency of the stomach in gastric catarrhs is controverted by the author, on the ground that this condition rapidly disappears as soon as fermentation in the stomach is arrested. The delay in stomach evacuation is attributable to the action of organic acids in producing spasms at the pylorus. Noorden recommends in the therapy of chronic gastritis the administration of a regulated quantity of albumen, fats and carbohydrates, sufficient being given only to maintain the general nutrition, and states that by the avoidance of all superfluous nutriments we will favorably influence the local affection. The lack of appetite should be overcome by the patient's own will power. Stimulant stomachics, especially orexin, should not be given, on account of their harmful effects. Rest in bed is indicated, for the reason that less food will be consumed and the stomach less taxed. The food which is best adapted to supply the body with fats and carbohydrates is milk, especially if fortified by the addition of butter and lactose.—*St. Petersburger Medic. Wochenschr.* No. 1, 1891.

CHLORALAMID.

Dr. W. G. Killebrew, in the *Memphis Medical Monthly*, states that he has used chloralamid in hysteria, acute mania, monomania, typhoid fever, also in surgical operations, and when unattended with much pain, with as good results as could be hoped for in all cases. He has used it in cases of insomnia and neurasthenia, and found that it produced all the sleep necessary, patients feeling much refreshed the following morning, with no after effects that he could discern. He noticed only two instances of delayed action, and in these two cases the hypnotic effect was continued into the next day, a result so frequently noticeable in the administration of sulfonal. His deductions were these: That in any case, almost without exception, unattended with pain, it would produce sleep. That its analgesic power, though slight, would meet a good per cent. of cases attended with pain.

Compared with chloral:

1. It is more agreeable to the taste and consequently more easily administered.
2. Rarely causes digestive disorders.
3. Does not depress heart or circulation

4. Seldom produces cerebral disturbances.

As compared with sulfonal :

1. Much more prompt in its action.

2. Being more soluble it can be administered more easily.

3. Sleep nearly always passes away by morning.

4. It is only about one-half as expensive.

DIPHTHERIA, WITH SPECIAL REFERENCE TO ITS TREATMENT WITH HYDROGEN PEROXIDE.

Whether the false membrane in the throat be the primary source of infection or the local manifestation of a constitutional disease, says Dr. Dickey, all agree that it is an element of great danger, and has to be removed as quickly and as thoroughly as possible, and at the same time doing as little violence to the surrounding healthy tissue necessary. The poison invades very quickly any denuded or abraded surface, consequently much care should be exercised in whatever remedies we may use.

Peroxide of hydrogen is a colorless, tasteless liquid, and when applied to a diseased membrane, causes little or no pain, and Dr. D. knows of nothing in the whole materia medica that will dissolve the diphtheritic membrane so quickly and thoroughly, and yet leave the healthy mucous membrane intact.

Dilute it twenty-five per cent. (although it can be used full strength), and apply with an atomizer. This can be repeated until effervescence ceases, when the membrane will be found to have practically disappeared, leaving a whitish surface. If the nose is invaded, it can be applied there with equal satisfaction. Absorb all the watery secretions from the nostrils with blotting-paper or absorbent cotton, and then apply the peroxide. After using the peroxide, use a solution of chloral hydrate, glycerine, and water, either as a gargle or with an atomizer.

At the same time, bichloride of mercury, tincture of the chloride of iron, with or without chlorate of potassium, or such other remedies as may suit the judgment of the individual prescriber, or be applicable to the case in hand, may be used. The writer prefers the bichloride.

Coupled with this should be given good digestible food at regular intervals, of which milk should form the basis, and such stimulants, from time to time, as the individual case may demand. The constitutional treatment is not less important than the local, and consequently must be attended to from the outset. When the temperature exceeds 103 5°, sponge the entire body with tepid water as often as may be necessary to bring it below this point. Pellets of ice internally will allay thirst and relieve very materially the turgid condition of the blood-vessels, and should not be omitted. Ice may also be applied to the throat in a rubber bag or a bladder, relieving greatly the inflamed glands.—*Ann. Gyn. Pæd.*

MEDICINE.

ALBUMINURIA CAUSED BY ANTIPYRINE.

Dr. E. L. Thompson, in the *Virginia Med. Monthly,* calls attention to a case of albuminuria caused by antipyrine.

A gentleman from New York came to Dr. Wm. A. Hammond's Sanitorium for Diseases of the Nervous System with locomotor ataxia. His urine was so heavily loaded with albumen that it almost solidified on boiling. There was so much œdema of the lower extremities that he could hardly put on his shoes; and there was also considerable puffiness under the lower eye-lids. Dr. Thompson found that he had been taking for some time, nearly every night, large doses of antipyrine—often as much as sixty grains a night. This would always stop the ataxic pains. Dr. Thompson examined his urine twice a day, and found much albumen in the morning, and very little or none in the evening discharge. It was then, on questioning, he found out about the antipyrine. It was suspected that the antipyrine caused it, on account of there being no albumen in the evening. The antipyrine was stopped, and since then, the albumen has disappeared, and the œdema is much less.

TREATMENT OF PHTHISIS BY ARTIFICIAL ATMOSPHERES UNDER PRESSURE.

A paper by M. Germain Sée on the subject of the treatment of phthisis by continued inhalation of medicated air under pressure, appears in the *Bulletin de l' Académie de Médicine,* No. 15, 1891. The drugs used were creosote and eucalyptol, their origin and action being fully referred to in the paper. The patients were placed in a closed chamber into which air was forced to an increased pressure of about half an atmosphere, after passing through a solution of the drugs. The pressure was increased gradually, and the sittings were prolonged to two, three, or more hours according to the patient's feelings. They took place every day, and the effect upon the general health was beneficial

rather than the reverse, whilst a very marked improvement was noted in the symptoms of the disease. Cases of phthisis in early as well as advanced stages were treated with satisfactory results. In two cases of fœtid bronchorrhœa of two years' duration, a complete recovery was brought about in the course of five weeks. M. Germain Sée claims for this method of prolonged inhalation under pressure that the actual absorption of the antiseptic drug is more complete, and approaches more nearly to the point at which it is assumed that morbific organisms may be annihilated. It is harmless in itself, and gives rise to no unpleasant consequences such as may follow the continued introduction of creosote subcutaneously or by the stomach. Inhalation of creosote vapor at ordinary atmospheric pressure has long since been proved to be insufficient for the purpose of checking the progress of tubercle. Improvement of appetite, gain of weight, diminution of cough and expectoration, and subsidence of fever would appear to be the most striking of the changes brought about by the treatment.—*Brit. Med. Jour.*

ANGINA PECTORIS: ITS NATURE AND TREATMENT.

Dr. R. Douglas Powell, in *The Practitioner*, argues that angina pectoris is a disturbed innervation of the heart or vessels, associated with more or less intense cardiac distress and pain, and a general prostration of the forces, always producing anxiety, and often amounting to a sense of impending death, and concludes that:

1. In its purer forms we observe disturbed innervation of the systemic or pulmonary vessels causing their spasmodic contraction, and consequently a sudden extra demand upon the propelling power of the heart, violent palpitation or more or less cramp and paralysis ensuing according to the reserve power and integrity of that organ—*angina pectoris vasomotoria.*

2. In other cases we have essentially the same mechanism but with the extra demand made upon a diseased heart—*angina pectoris gravior.*

3. The trouble may commence at the heart through irritation or excitation of the cardiac nerves, or from sudden accession of anæmia of cardiac muscle from coronary disease—*primary cardiac angina.*

4. In certain conditions of blood or under certain reflex excitations of the inhibitory nerves, always, however, with a degenerate feeble heart in the background, we may observe intermittence in its action prolonged to syncope—*syncopal angina.*

"TRAUMATIC NEUROSES."

"This is a convenient term, but, like other terms which are convenient, it is apt to include far too much. In this country the most important traumatic neurosis which is met with is no doubt the so-called, 'railway spine,' and it may be that cases placed in this category are as varied as those which Hoffman (*Berlin. klin. Woch.*, No. 29) found among a series of twenty-four cases of 'traumatic neurosis.' Of those twenty-four, ten were found to have undoubted signs of organic mischief; in six the symptoms were partly the result of exaggeration and partly of simulation; in eight there was malingering, proved to be so after careful observation for several weeks. The author protests against the use of the term for such varied conditions, pointing out that in a so-called traumatic neurosis we may have to deal with organic nerve injury, with hysteria, the result of injury, with shock to the cerebro-spinal system, with neurasthenia, or even with a true psychosis."—*Lancet.*

THE DIAGNOSIS OF MOTOR INSUFFICIENCY OF THE STOMACH.

Leo Silberstein (*Deutsche medicinische Wochenschrift*, February 26th) has recently made a series of experiments in Senator's clinic to determine the value of the salol test in estimating the motor activity of the stomach. The test is based upon the fact that salol when given by the mouth, is not absorbed in the stomach, but passes on unchanged to the bowel. There meeting an alkaline fluid, it is split up into phenol and salicylic acid, which latter is absorbed and afterward secreted in the urine. Its presence in the urine is detected by its violet reaction with chloride of iron.

Ewald's method was to give 15 grains of salol after the principal meal. Then in thirty minutes the urine was tested for traces of salicylic acid. He found that in healthy individuals the reaction always appeared in an hour at the latest. Any delay beyond this time indicated a slow passing of the salol into the bowel, or, in other words, a motor paresis of the stomach. Brunner, however, showed that Ewald's method was unreliable. His investigations proved that there was no fixed physiological time for the first appearance of the salicylic acid in the urine In the same individual under like conditions the interval may vary greatly

from time to time. These statements of Brunner were confirmed by Huber, who at the same time observed that in some persons the urine continued to show the presence of salicylic acid for a remarkably long time after the ingestion of the salol. This led him to think that perhaps the time of *disappearance* of the reaction might be more important than that of its *first appearance* in the urine. And, in fact, some experiments based upon this idea enabled Huber to state that an abnormally long duration of the salicylic-acid reaction pointed to a disturbance of the motor activity of the stomach. This theory, in turn, has been attacked by Decker and Pal, who believe that atonic and catarrhal conditions of the bowel may cause the prolonged reaction, though the stomach may be normal in all respects. Silberstein therefore proposed to repeat Huber's experiments, but on a much larger scale, and with special reference to the points raised by Decker and Pal. He made his first test of the urine twenty-four hours after the salol had been taken, and repeated it at intervals of six hours until he was satisfied that the drug had been entirely excreted. He insists upon the necessity of this procedure, stating that in some cases of marked motor disturbance of the stomach there was no reaction at the end of twenty-four hours, and yet after thirty or more hours had elapsed the reaction appeared. He made upward of 148 different experiments upon 76 individuals, and the following are his conclusions:

1. In healthy persons salol is entirely eliminated from the body within twenty-four hours.

2. In gastrectasia the elimination of the salol is always delayed, the reaction being invariably found after thirty-six hours. This is not the case when the stomach is simply displaced, hence this test serves to distinguish the dilated from the displaced organ, conditions which are easily confounded with each other.

3. In atonic conditions of the stomach there is also usually a delay in the elimination of the salol, but not to the extent noted in gastrectasia. It is the exception to find the reaction after thirty-six hours in cases of atony, whereas it is the rule in dilatation of the stomach. Here, again, this method is of diagnostic importance.

4. The condition of the bowels does not impair in any way the value of the salol test as modified by Huber.

Silberstein admits that Leube's method of examining the gastric contents two hours after a test breakfast is without doubt our best means of judging of the motor activity of the stomach. There are cases, however, in which, for one reason or another, it is impracticable to introduce a tube into the stomach, and in these the salol test may be relied upon as entirely trustworthy.—*N. Y. Med. Jour.*

THE DIAGNOSTIC SIGNIFICANCE OF VENOUS HUM IN THE NECK; A STUDY IN STATISTICS.

Dr. Bewley said he had been induced to collect statistics bearing on this subject by reading a paper by Dr. R. Apetz, "On the Significance of Venous Humming Murmurs for the Diagnosis of Anæmic Conditions," in *Virchow's Archiv.*, vol. 107. He called attention to the differences of opinion held on this subject—some writers attributing considerable diagnostic importance to the presence of a murmur; others believing the phenomenon to be one of no importance. Dr. Bewley then related the details of his investigation. He examined only healthy individuals; he only examined individuals between the ages of 16 and 26, because age has a very important influence on the production of these murmurs. All the cases were examined in an upright position, either sitting or standing. He divided his cases into three classes:—1. Anæmic. 2. Slightly or doubtfully anæmic, *i. e.*, cases which presented no appearance of anæmia, but yet suffered from some of the symptoms of this condition, or *vice versa*. 3. Not anæmic. He examined in all 51 young men and 149 young women. Of these 22 belonged to the anæmic class, 31 to the slightly anæmic, and 147 to the not-anæmic. In 22 anæmic there were 19 murmurs, equal 86·4 per cent. In 31 slightly anæmic there were 27 murmurs, equal 87·1 per cent. In 147 not-anæmic there were 85 murmurs, equal 57·9 per cent. Dividing up the not-anæmics into male and female—in 104 females there were 64 murmurs, equal 61·5 per cent. In 43 males there were 21 murmurs, equal 48·8 per cent. The conclusions Dr. Bewley drew from these statistics were the following:—1. Murmurs are more common in the anæmic than in the not-anæmic. 2. More than half of those young persons who are not-anæmic have a venous hum in the neck. 3. The presence of a hum is not of any diagnostic importance in any individual case. The loudness of murmurs is not a matter of much diagnostic importance. In his cases Dr. Bewley noticed 15 very

loud murmurs, distributed as follows:—In 22 anæmic, 3 loud murmurs, equal 13·6 per cent. In 31 slightly anæmic, 5 loud murmurs, equal 16·1 per cent. In 147 not anæmic, 7 loud murmurs, equal 4·8 per cent. He had noted some of the loudest murmurs in particularly rosy and full-blooded persons, and therefore did not attribute any diagnostic value to even the loudest murmur. He added that Dr. Apetz's conclusions based on very elaborate statistics, were almost identical with his own.—*Med. Press.*

ÆTIOLOGY OF BRIGHT'S DISEASE.

Dr. Agnes Bluhm has studied the apparent causation of all the cases of morbus Brightii and albuminuria that were treated in the Cantonal Hospital of Zürich, from the beginning of 1884 to July 1, 1889. The cases numbered in all 8,442, and after a careful analysis lead to the following conclusions: 1. The chief causes of acute Bright's disease are the acute specific fevers, and nearly all of these are liable to be complicated by nephritis. 2. The apparently uncommon occurrence of chronic Bright's disease as a sequel of acute infective diseases is due partly to non-pathological causes, but also in some measure to the latent and therefore undetected course of chronic nephritis. 3. The occurrence of nephritis as a complication does not depend on the intensity of the primary specific disease. 4. The course of the primary affection and that of the nephritis complicating it are not mutually related.—*Deutsches Archiv für klin. Medicin*, January 8, 1891.

A FORM OF GINGIVITIS COMMON TO MEN AND DOGS IN INDIA.

Surgeon J. R. Roberts, of the Indian Medical Service, describes gingivitis which is often mistaken for a symptom of scurvy, but which has distinct characteristics of its own, and is entirely a local disease. It is characterized by a bright red velvety condition of the gums; its almost invariable limitation to the front of the mouth; the ulceration that surrounds the bases of the teeth, generally the incisors, which process in advanced cases continues to extend, destroying the alveolus and exposing the fangs, until the teeth remain but loosely attached or drop out; the tendency to hæmorrhage on pressure or the slightest injury; the occurrence of an exactly similar process in dogs, remarkably limited in them to incisors and canines, whereby their small front teeth are frequently lost; the acid reaction of the mouth and the fetid odor given off.

Microscopic examinations of scraping show a large number of different micro-organisms. The disease is not limited to natives, but is common enough among British soldiers. Its worst effects are seen in a hot moist climate. The disease is essentially a slow chronic process. The treatment indicated is a light scraping of the ulcerations, touching them with strong carbolic acid or other antiseptic, and an alkaline mouth-wash.—*Boston Med. Surg. Jour.*

SURGERY.

TEMPORARY RESECTION OF THE CRANIUM.

Wagner (*Centralblatt f. Chirurg.*, 1891, No. 2) describes two cases in which he has used his method of "temporary resection of the cranium," first described in No. 47 of the above for 1889. Both cases, given somewhat in detail, demonstrate that the operation is very easy to do, and that the resected piece reunites both quickly and without reaction. In both instances the part resected was about one-fifth of the entire cranial vault, which leads the author to believe that a still greater amount will heal in the same way, and he would not fear to resect two-fifths or more if necessary. Naturally the isthmus of the flap must be correspondingly broader. Just as we have trephined, sometimes, the skull in different places, so we can make this temporary resection in one or more places. First, corresponding to the piece of bone to be removed, a curved incision is made whose ends converge toward each other. This flap must overlap the bone to be raised one-fifth to two-fifths of an inch. The soft parts retract, and the incision gapes in a sickle-shaped way, with the point toward the base of the flap. The flap is now firmly pressed upon the cranial surface, and the pericranium smoothly cut through along its border. With a small, fine chisel a little trough is made in the bone along the line of the incision. For the further steps of the operation, a moderately thick but small chisel, abruptly beveled on one side, is used. This is applied in an oblique manner. One can work his way through the cranium most quickly with this. When all the bone is chiseled through, a small, thin chisel is used to cut through that part of the bone covered by the isthmus of the flap. The skin and bone are now raised together with the aid of a small elevator. The replacing later on is very easy to effect.

When the chisel is applied obliquely, the inner circumference is naturally less than the outer. The soft parts are then sewed together with fine sutures, and one of the under angles of the wound left open. The suture line does not correspond with the bony defect, but is somewhat removed from it, the soft parts overlapping this, in accordance with the plan of the incision above mentioned. In this way an adherent scar between bone and skin is avoided.

Regarding the indications for "temporary resection," or "osteoplastic trepanation," the author regards it, in general, indicated wherever in the uninjured bone the cranial vault is to be opened, not only in cases where we expect with certainty or probability to find removable alterations, but where we only suspect them; for instance, many cases of epilepsy of doubtful traumatic origin. This form of exploratory opening of the cranium the author regards fully as justifiable and no more dangerous than exploratory laparatomy.—*Buffalo Med. and Surg. Journal.*

THE TREATMENT OF WHITE SWELLINGS.

Under this title, Lucas-Champonnière has written (*Journal de Médecine et de Chirurgie*, Nov. 25, 1890) a very interesting paper, giving his views, based on a wide experience, as to the treatment of this variety of tubercular disease. He considers that the methods of treatment have been much modified by modern improvements, both as to therapeutic and operative measures. Topical treatment he regards as particularly happy in children, upon the development of whose bones operative interference exercises a disastrous influence. Immobilization he has found not to possess the beneficial influence generally attributed to it, and he thinks that while there are a certain number of cases in which it ought to be employed, it is, as a rule, abused. Its principal object should be to prevent deformity.

Care of the general health plays a principal part in the treatment, and the value of country or sea air must not be overlooked. As to the medicines to be relied upon, the iodide of potassium is mentioned as *the* one *par excellence*, while tonics, cod liver oil, quinine and arsenic are also useful. Iron is not spoken of with favor, and the iodide of iron does not, according to the writer, possess the virtues of iodide of potassium.

As to the direct treatment of the affected joint, revulsion, by means of the thermo-cautery, superficially applied, is considered a measure of the greatest value. The cauterizations are repeated about every fortnight, and are made to extend beyond the limits of the joint. Next to cauterization in importance, compression is mentioned. This is to be effected by means of flannel bandages firmly applied, and renewed as often as they become loose. Before the bandage is applied, the joint is first enveloped in a layer of either peat wadding (which has been found to best answer the purpose), oakum, tow, or wool, all of which are superior to cotton.

Of topical applications, mercury is considered the best, the use of iodine or turpentine being characterized as a mistake. The mercury is employed in the form of cerate, made according to an old formula of Scott, of Dublin, which is as follows: Soap cerate, one ounce; double mercurial ointment, one ounce; powdered camphor, one drachm. Champonnière regards mercury as the principal source of success in the treatment, the absorption of the drug into the tissues of the part making possible its microbicidal action. Previous to the application of the cerate the skin is thoroughly cleansed and then rubbed with camphorated spirit.

After the dressing is made, if fixation is required, it is accomplished by means of a plaster bandage. If abscesses form in the course of the disease, they are not interfered with unless large, in which case they are opened under anæsthesia and washed out with a 5 to 8 per cent. solution of chloride of zinc. Sinuses are injected with the same solution, sometimes with an emulsion of iodoform, and, as a substitute for the latter, naphthol-camphor is mentioned.

Continuous extension is regarded as most seaviceable in the case of hip disease, and is employed, not only because of the relief of pain which it secures, but because it promotes the conditions which favor the possibility of cure.

As to operative treatment, when necessary, the view is taken that it should be complete, Arthrectomy is considered as hazardous and incomplete, while resection is spoken of as "the only and true operation for articular and osseous tuberculosis."

The paper concludes with an epitome of eighty-one resections, the results of the operations upon the knee-joint being particularly excellent. In no less than forty excisions of this joint cure was effected without the occurrence of any suppuration whatever. Antisepsis was rigidly carried out, and in order to prevent injury to the silver

wire employed to appose the ends of the femur and the tibia, carbolic acid solutions were substituted for those of bichloride generally used.—*Univ. Med. Mag.*

THE INDICATIONS FOR SURGICAL INTERVENTION IN TRAUMATIC HYSTERIA.

In an interesting article on the relations of hysteria to surgery, by Georges Guinon (communicated by Dr. Baaz), the author states that surgical interference in this affection is only indicated in cases of old contractures with formation of fibrous tissue, and also in persistent monoplegias with severe trophic disturbances. As a general rule, the surgeon is not called upon to interfere in hysteria, for the fact that a lesion sine materia is the cause of the symptoms and warrants us, in a certain sense, of expecting a favorable prognosis. The prognosis is never certain, however, as regards the possibility of a cure of the attacks, but we know that even when contractures have persisted for many years, we are not justified in giving up all hope of a cure. If the contractures are of spasmodic origin, they will sometimes disappear spontaneously during an attack, or may be relieved by massage, electricity, magnetism, or hypnotic suggestion. In all these conditions no surgical interference is demanded. The question comes up whether we are to interfere in cases where the contracture is associated, for example, with a shortening of tendons, with muscular atrophy and various trophic disturbances. On this subject opinions are still much divided. We may be tempted to divide the fibrous bands formed in a limb affected by contractures, but whether this is permissible must depend upon each case, and no general rule can be formulated. As long as a spasmodic conditon persists, no operation is warranted. To make sure whether a contracture is due to spasm or a shortening of muscles and tendons, the patient is placed under chloroform anæsthesia, which will show to what extent the contracture depends upon spasm and shortening. The surgeon is not justified in interfering until all spasm has ceased.

In his lectures, Charcot reports a case in which attempts were made to affect a cure by stretching of the nerves. The result was not satisfactory. Sometimes these patients request from their physicians procedures of much greater severity. Thus one of Debove's patients, in whom a spasmodic contracture of the arm had resulted from application of a splint, urgently demanded an amputation, on the ground that the limb was perfectly useless. The extremity presented a deplorable appearance, the muscles had atrophied, but gave no degeneration-reactions, the nails had deeply penetrated the palm of the hand in consequence of the spasm, and had produced unhealthy ulcers. Debove brought the case before the Societé Médical des Hopitaux, and asked the advice of the members regarding its treatment, and most of those present spoke against an operation.

In general we may say that, in hysterical subjects, the surgeon is only called upon to intervene when he has to deal with the sequelæ of a former neurosis. He should not attempt to treat the hysterical affection by surgical means. The relations of hysteria to surgery are numerous, and may be illustrated in the following conclusions:

1. Traumatisms which do not require the direct intervention of the surgeon, but are capable of evoking a number of surgical affections, may, in persons predisposed thereto, produce hysteria and hysterical manifestations which may bear a deceptive resemblance to diseases belonging to the domain of external pathology.

2. On the other hand, the surgeon may give rise to hysterical seizures by operations undertaken for curative purposes.

3. The surgeon may be inclined to interfere in conditions of hysterical character, but the indications and contra-indications to operation should be based upon a thorough knowledge of hysteria.—*Wiener Mediz. Presse.*

GYNÆCOLOGY.

AN ENORMOUS OVARIAN CYST.

There has recently been a patient in the obstetric ward of St. Thomas's Hospital, under the care of Dr. Cullingworth, suffering from an enormous ovarion cyst. She was a widow aged forty-five, who had had no children, and who had been the stewardess on a well-known line of Channel steamers for many years. The swelling of the abdomen was first noticed nine years ago; for three years and a half it had been so large that she had been unable to go beyond her own garden; for two years she had not left her room, and for six months she had not been out of bed. She had persistently refused operation until recently. After admission on April 9th the abdomen was found to be uniformly and enormously distended by a fluctuating swelling, consisting of one large cyst, distending the lower part of the thorax, and hanging down, as she sat in bed, as far

as the knees, completely concealing the thighs. The girth 1½ in. above the umbilicus was 67 ins.; the measurement from the ensiform cartilage to the symphysis pubis was 38 ins. The body was greatly emaciated; she presented a most remarkable appearance, but was very cheerful. There was some albuminuria. On April 13th, preparatory to operation and in order to diminish the shock, the abdomen was punctured by a fine trocar, attached to a long India-rubber tube, with the lower end placed under a measured quantity of solution of carbolic acid, and the fluid from the cyst allowed to flow away for seven hours. Seventy-four pints of thick grumous chocolate-colored fluid escaped, containing much altered blood. The day after this an attempt was made, under ether, to remove the tumor. The whole of the anterior surface of the cyst was adherent to the abdominal wall. There were comparatively few adhesions posteriorly, but more in the pelvis. At the end of half an hour the patient became seriously collapsed and the cyst was quickly extracted. It was a large thick-walled single cyst of the left ovary. The patient died before the closure of the abdominal wound had been completed, in spite of persistent efforts at resuscitation. The total weight of the tumor and its contents—including that of the fluid removed on the previous day—was 154½ lbs., or 11 st. ½ lb. The weight of the patient was not ascertained, but must have been much less than this. This is probably the largest abdominal tumor of which there is any record; the largest mentioned in the series of 1,000 by Sir Spencer Wells did not weigh more than 125 lb.—*Lancet.*

BAGOT ON MASSAGE AS APPLIED TO THE TREATMENT OF INCONTINENCE OF URINE IN FEMALES.

A full account is given of the treatment of this affection by Brandt's method, by Sänger's method (which consists in dilatation of the vesical sphincter and massage), and also by distension of the bladder with warm water, as practiced by Nissen and H. Marion Sims. The author has cured three cases by the use of Brandt's system, omitting some of the steps which he considered useless. The most essential part of this method of treatment was the direct treatment of the neck of the bladder by the finger in the rectum or vagina. In children the finger was used in the rectum.

The first patient had suffered more or less from incontinence of urine since her last confinement, eighteen months ago, but had become much worse during the last nine months. She was treated at first every day for four days by Brandt's system, omitting "the lifting of the bladder." After this she was treated sometimes every second and sometimes every third day for twenty-nine days. At the end of this time a permanent cure was effected.

The second case, an unmarried woman of twenty-four, had suffered from incontinence from childhood. She was treated by Brandt's method, omitting the "exercises for the adductors of the thighs" and the "bladder lifting," every second day for five weeks, at the end of which she declared herself quite well, and was discharged.

The third case was a woman of forty, who had ten children, and had suffered from incontinence for three years. The treatment in this case lasted four weeks. Dr. Bagot's reason for discarding the "bladder lifting," altogether, was because, from what he had seen during laparotomies, he knew that it would be impossible to sieze hold of the bladder when in an empty state, and elevate it by the manœuvre described by Brandt. The "exercises for the adductors" might be of use in those cases where the pelvic floor was greatly relaxed, and even in these, though it was probably of use in bracing up the parts, it was not an essential in the cure of either enuresis or of uterine displacements. The chief part of this method, as applied to enuresis, was the direct treatment of the neck of the bladder. The method of Sänger was one to which the author wished to draw special attention. Dr. Sänger considered that the basis and cause of this affection consisted in a weakness or paresis of the vesical sphincter, and perhaps a certain tenuity of the muscular bundles. This method was not indicated where there was very great dilatation of the bladder neck and whole urethra. In these cases, artificial removing of the urethra in some way was more likely to succeed. Dr. Bagot had treated two cases by Sänger's method.

Massage, by distension of the bladder with warm water, was of use in case of contraction of the bladder, following long-continued incontinence of urine from any cause, the holding capacity of the bladder being then diminished.

While recommending these treatments, Dr. Bagot urged the necessity of careful diagnosis in every case, and that the cystoscope should be more generally used.—*Med. Press.*

OBSTETRICS.

IODOFORM GAUZE IN POST-PARTUM HÆMORRHAGE.

Dr. Velitz, of Buda-Pesth (*Orvosi hetilap*, 1890, Nos. 10 to 12) describes thirteen cases where he employed plugs of iodoform gauze for flooding, during and after delivery, and (in two cases) in the course of the puerperium. He finds that iodoform gauze is a perfectly aseptic medium in obstetrics. It is of permanent value as a hæmostatic in flooding from atony of the uterus. Only a small amount of the gauze should be packed in the uterus, so that retraction of that organ may not be hindered. Iodoform gauze is useless, and indeed dangerous, in uterine hæmorrhages due to abnormal condition of the blood. Being hygrometric it promotes hæmorrhage. In this form of flooding weak solutions of perchloride of iron act best. Hæmorrhage from high laceration of the cervix can only be safely checked by aid of the suture. When bleeding occurs after delivery or late in childbed, through the presence of a fibroid, the only effectual check is a thorough plugging of the uterine cavity with iodoform gauze; the cavity must be well stuffed with that material.—*Brit. Med. Jour.*

FETID MILK IN HUMAN MAMMARY GLANDS.

Dr. Jorissenne had under his care in 1874 a patient of slightly tuberculous aspect, though now, in 1891, she is in good health. On October 5, 1874, she was delivered by forceps. She suckled her child freely till December 7th, when she was absent from it for seven hours and a half. This space of time included a drive one hour long, five hours and a half walking, and one hour's rest for refreshment. Immediately on her return home she gave her child the breast. The milk was horribly fetid—like rotten eggs. It made her feel ill, and her relatives could not stay in the same room with her. Yet the infant sucked with avidity; however, it was violently sick. Next day the milk was sweet, and the child and also the mother quite well. The breasts showed no sign of hardness, engorgement, etc. The nipples were healthy. The patient told Dr. Jorissenne that on several previous occasions she had noticed that when she delayed giving the child the breast at the usual times the milk became fetid. Dr. Jorissenne had no further opportunity of observing this putrefaction of milk, as it did not recur. The patient was red-haired; but he has carefully examined the milk of many red-haired women since 1874, and failed to find that it showed any special tendency to putrefy or even turn sour, in the open air or in a close room, more quickly than the milk from a black or fair-haired woman. The avidity with which the infant imbibed the putrid milk was remarkable; its stomach was more sensitive than its nose and tongue. Evidence as to the acuteness of taste in the infant is imperfect. During the first few days of extra-uterine life the sense seems undeveloped. The child will take solutions of raw salines without syrup, though a few weeks later it will reject the same compounds nicely flavored. The sense of sweetness is early developed. At the end of a few weeks an infant likes sugar, and dislikes cow's milk unless sweetened artificially. Children of six months, or older, will lick ill-tasting colors off their toys. In Dr. Jorissenne's case, the child liked a milk that smelt intensely fetid and must have tasted nasty, according to an adult's idea of taste.—*Archives de Tocologie.*

DURATION OF PREGNANCY.

Oliver concludes, after very careful observation, that the duration of pregnancy in the human female varies as much as it does in the case of many of the lower animals. Issmer, reckoning only cases in which the fœtus was well developed, asserts that the duration ranges from 260 to 304 days. But Oliver believes there must be some error in this statement. If we reckon from the last menstruation, we must be careful to ascertain the exact date of the cessation of this, for it will be remarked that where the duration of the discharge varies little, the woman, when asked, is more likely to give the date of beginning than the date of cessation of the last menstruation, and in this way mistakes may arise in our calculation to the extent of four or more days. The majority of authors are agreed that in reckoning the duration of pregnancy in woman, we ought to fix the probable date of delivery on the 278th day from the cessation of the last menstruation. He is of the opinion that the best results will be obtained by ascertaining, first, the date of the cessation of the last menstruation, and then the usual duration of the inter-menstrual period in each given case; the number of inter-menstrual days should then be divided by two, and it will be found that the 260th day from the middle of the inter-menstrual period will most

probably be the date of confinement.—*Liverpool Medico-Chirurg. Journal.*

PÆDIATRICS.

THE PREVENTION AND TREATMENT OF SCARLET FEVER.

Dr. W. Bezly Thorne, in the *Lancet*, says, the prevention, treatment, and, perhaps, the cure of scarlet fever are of so great importance to the medical profession and the public at large that he ventures to offer for publication the following brief notes of a case which was under his care at the commencement of this year. If it stood alone, he would be compelled to admit that no practical conclusion could safely be drawn from it; but he has since gathered, from the perusal of a paper read before the Epidemiological Society by Mr. J. Brendon Curgenven, that many other cases of the same disease have been somewhat similarly treated with the like striking results, and he thinks that it cannot fail to serve a useful purpose to invite others who have practiced the treatment advocated by Mr. Curgenven to bring forward the results which they have obtained.

The patient, fourteen years of age, but of the physical development of ten, was seen within little more than an hour of the appearance of the rash, and was reported to have been "bilious and shivering over the fire" for something more than two days. The face was flushed and dotted with a scarlatiniform rash; the eyes were red and suffused, and both tonsils swollen, inflamed and ulcerated; the pulse was 120 and the temperature 103°. She was immediately ordered to take internally every four hours five minims of the oil of eucalyptus globulus emulsified with powdered acacia, to use every hour a gargle of carbolic and tannic acids suitably diluted, to undergo daily inunction with an emulsion of eucalyptus oil of the strength of half a drachm to the ounce, and made up of glycerine, to promote adhesion to the skin, and to have the scalp and hair daily sprinkled with a spirit lotion containing eucalyptol, with a small quantity of almond oil. On the following morning—that is, in rather more than twelve hours—Dr. Thorne found that the rash had receded from the face. He inquired of the nurse whether any was to be seen on the chest, which she had washed and anointed two hours previously, and was informed that it was "well out," but on examining that region found that it presented absolutely none. It was at that time making its appearance on the lower extremities, was well marked in the evening, and on the following morning had entirely disappeared. No desquamation followed. The chart tells the rest with sufficient detail. It should be added that although the house was occupied during the illness and up to the departure of the patient to the seaside on the twenty-second day by six full-grown adults and four younger persons whose ages range from nineteen to six, besides the sick one, the infection has not spread. A sheet, which was from time to time moistened with a dilution of sanitas, was fixed by the nurse to the door of the sick room in accordance with the instructions of the institution from which she was sent.

HYGIENE.

THE TRANSMISSIBILITY OF HYDROPHOBIA FROM MAN TO MAN.

The fact that no instance is on record of hydrophobia having been transmitted from man to man has given rise to a doubt as to whether the saliva of human beings suffering from the disease possesses the same virulent properties as that of the dog similarly affected. In not more than five or six of the ten thousand patients treated at the Pasteur Institute was the lesion due to bites inflicted by human beings, and it is evident that statistics bearing on so small a number of cases are of no value one way or the other. It has, however, been proved experimentally, that the saliva of human beings, having succumbed to hydrophobia, produces the disease in animals by inoculation, though the incubation period is somewhat prolonged. It may, therefore, be taken as proved that the disease may be transmitted in this way from man to man. It is hardly possible as yet to affirm categorically the possibility of curing hydrophobia after the characteristic symptoms have made their appearance, but recent observations throw a doubt on the incurability of the disease even under these circumstances.—*Med. Press.*

VOLUNTARY CONSTIPATION.

In an article in the *Revue de l'Hypnotisme*, entitled "Voluntary Personal Uncleanliness," Dr. Galippe calls the attention of the authorities to the necessity of reforming the sanitary arrangements obtaining in most French educational establishments. Some facts related by him in this connection will be read with astonishment by those who are

not familiar with the horrible filthiness of most French closets. He says, "We need hardly remind the reader of the disgusting filthiness of most (school) closets, and I have known sensitive children who refuse to repair to these places until they were absolutely obliged to do so, such is their horror of the stench that there assails their nostrils, and the dirt they may bring away with them. I have known of many children who have suffered much from this voluntary constipation, and of others who, affected with diarrhœa, have for a whole week passed their motions into their clothing." Dr. Bourneville, in a notice of this article (*Progrês Médical*, February 14th) says that he has for years urged the necessity of endowing not only schools but also hospitals and barracks with decent closets. He has endeavored to convince the French public of the feasibility of such a stupendous feat by having constructed for his idiot and imbecile child-patients at the Bicêtre closets, the cleanliness of which strikes the French visitor with astonishment. M. Bourneville also demands for each school a complete set of bath-rooms, and calls for regulations rendering the use of a bath obligatory on the scholars.—Paris Correspondence of *The Lancet*.

MEDICAL CHEMISTRY.

ISOLATION OF A CHOLERA TOXINE.

Hermann Scholl (*Berlin. klin. Woch.*, October 13th, 1890) communicates an interesting paper giving the results of some experiments with a poisonous body isolated from cultivations of the cholera bacillus. He thinks it curious that in all previous investigations on the nature of the cholera toxine cultivations should have been used which had been grown in the presence of air, whereas, in his opinion, in order to imitate the conditions under which the cholera bacillus grows in the human intestine, the most essential point is that the culture be grown in the absence of air. In this assumption he follows Hueppe and Cartwright Wood, who, he considers, have satisfactorily shown that the cholera bacilli grow in the small intestine in the absence of oxygen, and that their extreme virulence or rapidity of poison production depends chiefly on this anaerobic growth. Other observers, among whom Petri may be cited, think that this point requires more rigorous proof than has yet been afforded. To obtain this anaerobic growth the author used the method introduced by Hueppe of growing the bacilli in raw eggs, by which means he holds that oxygen is completely excluded. The inoculated eggs were kept for eighteen days at a temperature of 36° C. When opened the contents were found to give off a very powerful smell of sulphuretted hydrogen, differing in this from cultures grown in air. He describes the white of the egg at this period as being fluid and watery, the yolk firmer in consistence and black in color. In order to test the toxicity of the egg contents 5 cubic centimetres of the fluid part were injected into the peritoneal cavity of a guinea-pig. The animal at first showed signs of paralysis, then convulsive movements, and died at the end of forty minutes. This proved that the fluid egg albumen was very poisonous. The author then proceeds to describe his method of isolating the poison. Shortly, it is as follows: The fluid part of the egg contents, which amounted to 150 cubic centimetres, was dropped into ten times its volume of absolute alcohol. The white precipitate thrown down was collected and digested with 200 cubic centimetres of water at 40° C. The effect of this was to dissolve only a very small quantity of the precipitate, which was then removed by filtration. Eight cubic centimetres of the transparent filtrate were then injected into the peritoneal cavity of a guinea-pig, and caused death in one minute and a half. This fluid entirely lost its poisonous properties on being boiled in the steam sterilizer for half an hour, whilst a short heating to 75° C. had no such effect. On the other hand, when placed at 40° C. *in vacuo*, over chloride of lime, the fluid was found next day to be completely inert. The author then subjected the poison to the usual chemical tests, and came to the conclusion that it was no ptomaine, but a peptone, differing, however, from the toxo-peptone isolated by Petri from aerobically grown cultivations. This peptone could be obtained in a solid form by dropping the watery solution into 8 to 10 times its volume of a mixture of the ether and alcohol, rendered faintly acid by acetic acid. The resulting precipitate was found to be insoluble in pure water, but soluble on the addition of an alkali. After repeating this precipitation and re-solution several times, pure ether was substituted for the mixture of ether and alcohol, and the peptone obtained after evaporation as a white bulky substance. A very small quantity of this dissolved in water was then injected into the peritoneal cavity of a guinea.pig. The

animal at once became totally paralyzed. After half an hour convulsive movements of the head and extremities set in, and, at the end of five hours the guinea-pig died. The author concludes, as the result of his experiments: 1. That the poisonous peptone, elaborated by the cholera bacilli under conditions of anaerobiosis from the albumen of the egg, is different from the toxo-peptone of Petri, since the latter was not decomposed on boiling, while the former was. 2. That this cholera pepto-toxine is much more poisonous than the toxines found by Brieger and Petri in cultures grown under aerobic conditions, since the poison obtainable from a single egg was capable of killing ten guinea-pigs in the space of ten minutes. 3. That these experiments are in favor of the contention of Hueppe and Wood that the cholera bacilli, when grown anaerobically, form a greater quantity of, and a more powerful, poison than when grown aerobically.—*Brit. Med. Jour.*

NEWS AND MISCELLANY.

THE MEDICAL NEWS.

Dr. Geo. M. Gould has succeeded Dr. Hobart A. Hare as editor of the *Medical News.*

VALEDICTORY ADDRESS AT THE YALE MEDICAL SCHOOL.

Dr. John S. Billings will deliver the annual address at the Yale Medical School on the Tuesday before the commencement.

RESIGNATION OF PROF. H. W. WILLIAMS.

Dr. Henry W. Williams has resigned the Professorship of Opthalmology in the Harvard Medical School, which position he has held for twenty years.

THE NEW HAMPSHIRE MEDICAL SOCIETY.

The New Hampshire Medical Society will hold its one-hundredth annual meeting at Concord on the 15th, 16th and 17th of June. The first two days will be devoted to literary work, and the third day to general business.

LEPROSY IN RUSSIA.

The rapid extension of leprosy in Russia has excited the alarm of the authorities, and the Town Council of Riga has voted a sum of 60,000 roubles to establish a Hospital for lepers, which is to be inaugurated in July. —*Ex.*

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

The Trustees of the American Medical Association have elected Dr. J. C. Culbertson editor of the *Journal.* Dr. Culbertson was for many years editor of the *Cincinnati Lancet-Clinic.* He assumed his duties on May 14th.

THE PROPOSED PAN-AMERICAN MEDICAL CONGRESS.

The proposition made at the last meeting of the American Medical Association by Dr. Chas. A. L. Reed, for a Pan-American Medical Congress, has met with much approval, and it now seems likely that this worthy project will be carried out.

THE JEFFERSON MEDICAL COLLEGE.

Dr. J. M. Da Costa and Dr. Roberts Bartholow have been elected Emeritus Professors in the Jefferson Medical College. Although Dr. Da Costa has given up the chair of Practice he will continue his valuable clinical lectures in the Jefferson College Hospital.

THE INTERNATIONAL HYGIENIC CONGRESS, 1893.

A movement is on foot, at Buda Pesth, to have the meeting of the International Hygienic Congress, in 1893, held in that city. Professor Fodor is taking an active part in furthering the scheme, and the Hungarian Government has already been approached unofficially on the subject.—*Ex.*

THE CROONIAN LECTURES.

Dr. Burdon Sanderson will deliver the Croonian Lectures of the Royal College of Physicians "On the Progress of Discovery relating to the Origin and Nature of Infectious Diseases during the last Twenty-five Years." The lectures will be given on June 9th, 16th, 23rd and 30th, at the Examination Hall, The Savoy, London. Considering the reputation of the author and the subject, these lectures will doubtless prove of exceptional interest.

CH. MARCHAND'S

PEROXIDE OF HYDROGEN

(MEDICINAL) H_2O_2 (Absolutely Harmless.)

Is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a Nostrum.

A REMEDY FOR DIPHTHERIA; CROUP; SORE THROAT,
AND ALL INFLAMMATORY DISEASES OF THE THROAT.

OPINION OF THE PROFESSION.

Dr. E. R. Squibb, of Brooklyn, writes as follows in an article headed "On the Medical Uses of Hydrogen Peroxide (*Gaillard's Medical Journal*, March, 1889, p. 267), read before the Kings County Medical Association, February 5, 1889:

"Throughout the discussion upon diphtheria very little has been said of the use of the Peroxide of Hydrogen, or hydrogen dioxide; yet it is perhaps the most powerful of all disinfectants and antiseptics, acting both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. The few physicians who have used it in such diseases as diphtheria, scarlatina, small-pox, and upon all diseased surfaces, whether of skin or mucous membrane, have uniformly spoken well of it so far as this writer knows, and perhaps the reason why it is not more used is that it is so little known and its nature and action so little understood. . . . Now, if diphtheria be at first a local disease, and be auto-infectious; that is, if it be propagated to the general organism by a contagious virus located about the tonsils, and if this virus be, as it really is, an albuminoid substance, it may and will be destroyed by this agent upon a sufficient and a sufficiently repeated contact. . . . A child's nostrils, pharynx and mouth may be flooded every two or three hours, or oftener, from a proper spray apparatus with a two volume solution without force, and with very little discomfort; and any solution which finds its way into the larynx or stomach is beneficial rather than harmful, and thus the effect of corrosive sublimate is obtained without its risks or dangers. . . ."

Further on Dr. Squibb mentions that CHARLES MARCHAND is one of the oldest and best makers of Peroxide of Hydrogen, and one who supplies it to all parts of the country.

CAUTION.—By specifying in your prescriptions "Ch. Marchand's Peroxide of Hydrogen (Medicinal)," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon. Never sold in bulk.

PREPARED ONLY BY

A book containing full explanations concerning the therapeutical applications of both CH. MARCHAND'S PEROXIDE OF HYDROGEN (Medicinal) and GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application. ☞ Mention this publication.

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

Clinical Lecture.

CONSUMPTION AND EMPHYSEMA—PLEURITIC EFFUSION—RHEUMATIC NEURITIS.

BY WILLIAM PEPPER, M. D., PHILA.,
PROFESSOR OF CLINICAL MEDICINE NIVERSITY OF PENNSYLVANIA.

CONSUMPTION AND EMPHYSEMA.

Gentlemen:—The first case that I shall call to your notice to-day, is that of a man of about forty years old. Until two years ago he has enjoyed fairly good health, when he caught cold, and had a persistent cough which lasted for several months. He also expectorated a large amount of purulent sputa, of a yellowish color. These symptoms, however, began to improve until in January of this year he took a fresh cold. The symptoms all became aggravated. The patient's cough increased, he raised a considerable amount of blood, his appetite failed him almost completely, and he gradually grew weaker and weaker. There were no night sweats.

Regarding the physical signs of this patient, we first notice that the color of his face is good. His finger nails are somewhat large and bulbous. This point alone has considerable diagnostic value, for these peculiar finger nails are often met with in cases of long standing lung trouble, and more frequently in chronic phthisis than in any other disease. The patient says that the trouble has always been on the left side. His sputa contains tubercle bacilli. In comparing the movements of each side of the chest, it will be seen that the right side expands more than the left.

You see that with very little effort we have already observed several important physical signs which will materially assist us in forming a diagnosis, as well as prognosis. These are the good color of the complexion, the peculiarity of the finger nails, and the decrease of chest expansion on the left side.

I cannot too strongly impress upon you the vast importance of carefully noting even the apparently most insignificant physical signs. The very one which we will perhaps regard as the least important, may be the very one that will ultimately give us a clue to the diagnosis. Physical diagnosis is, therefore, of the greatest importance, and cannot be too carefully studied. After your student life is over and you are well on in active practice, you will find that each year will unfold new truths to you, you will learn to attach greater importance to each physical sign, and you will after all feel convinced that nature is only beginning to unfold her mysteries to you.

Note once more, therefore, these physical signs. The right side of the chest moves more freely than the left. To make sure of this we practice palpation: laying our open hands over the chest. We can in this way feel the difference of expansion even more distinctly than we can see it. Our attention is also called to a marked pulsation in the epigastric region, which strongly simulates the thrill of an aneurism. Auscultation shows us that the pulsation is stronger here than over the heart. All these signs are most deceptive, the chances that they are due to real aneurism being not more than one in fifty. In all probability it is merely an abnormal pulsation of the healthy aorta.

In such cases we have no right to conclude that the patient is suffering from aneurism unless, also, there are evidences of tumor. But why have we this pulsation? Such a pulsation is likely to occur in cases of enlarged heart, when the right ventricle, which may be either over-charged, dilated or hypertrophied, rests against the diaphragm. In pleuritic effusions this same epigastric pulsation is observed. In this case, when the patient leans forward I can hear his heart pulsate in its normal region,

but when the patient is erect the epigastric pulsation is strong and the heart over its normal region becomes almost inaudible.

This shows that while the heart is acting feebly, yet that it is not displaced to the right. The probabilities are, in this case, that this epigastric pulsation is due to an enlarged right ventricle. We will now see what percussion will develop. There is a great deal of resonance here, the liver dullness does not begin until some distance below the normal line. On the left side we find an area of impaired lung reaching from the nipple to the heart dullness. Posteriorly, there is resonance everywhere. Let us now try auscultation. We find interesting tubercular breathing over the position of the primary bronchus. Over the area of dullness there is marked bronchial breathing both in expiration and inspiration. There are a few râles.

The patient has a pleural effusion on the left side. This would be the usual conclusion also from the visible examination, but it is disproved by finding a distended right heart laying on the diaphragm. Percussion over the right side was negative; but over the left nipple an area of dullness was found, that is to say, that the lower portion of the upper lobe, and the upper portion of the lower lobe is affected. Dullness in this region is rare; what can it be? I have seen similar dullness between the outside of the pericardium and the lung, but in this case no such condition exists. Here we have partial consolidation, increased respiration and increased vocal fremitus. Percussion and auscultation have elicited also another interesting symptom, namely, an enlarged right bronchus, in fact there is a cavity in the right bronchus caused by its enlargement. Without doubt this man's trouble was at first merely bronchial. You will remember, also, that we found his liver displaced downwards. The right lung is emphysematous and its limits are increased. Since January last, the man says, that he has been steadily losing flesh and growing worse, he having taken fresh cold—in other words he became tuberculous. This is the reason why, although ill so long, he still looks comparatively well, namely, he has not been affected with tuberculosis prior to last January. I think that it is a good thing for this man that his lung trouble is where it is and not at the apex of the lung, for, for some unknown reason, the apex heals much more slowly than any other part of the lung. Let me, however, warn you against making any too favorable prognosis in cases of this kind. Emphysema is not such a bad thing for a tuberculous subject to have. It is an undoubted fact that tuberculosis does not spread so rapidly in emphysematous subjects as in others; but the presence of the emphysema is often apt to mislead us, and lead us to believe that the lung is healthy where it is really diseased. The mistake is made by the emphysema giving rise to resonance or percussion over portions of the lung where really there may be nodules or even partial consolidation. And so while the apparent physical signs of your patient may be favorable, yet extensive disease may exist and you will be surprised at the sudden way in which your patient will grow worse and finally die. It is well, therefore, always to add, in these cases, a possible 33 per cent. to the extent of the pulmonary disease. Therefore, be guarded in your prognosis.

PLEURITIC EFFUSION.

The next patient is a young man suffering from pleuritic effusion. About two months ago about 55 fluid ounces of serum were drawn off. The patient's breath smells strongly of decomposed pus. His temperature has been very eratic, a hectic fever existing most of the time. He had been discharged but came in again a short time since with new evidences of pleuritic effusion. He coughs a good deal, and spits up a large quantity of pus. This time there is an effusion on both sides of the chest, but the contents of the chest is pus, and not serum. This pus has caused a softening of the pleura and a fistula communicating with the lung has formed. This accounts for the pus in the sputa. But as the pus goes out through this fistula, the air comes in, and we therefore have a case of pyo-pneumothorax. Since the patient has been in the Hospital this time, 48 ounces of pus have been drawn from the right side. There is still a large amount of liquid in the chest, capable of producing flatness and tympani. As I move the patient about I can hear the pus splashing with a metallic splash, that only exists when there is air in the pleural cavity. While the case is undoubtedly one of pyo-pneumo-thorax, we also observe that his finger nails are bulbous, and that the flesh is livid around the matrix. As I have said before in this lecture, this condition of the finger nails is of great diagnostic value. But, while the indications in this patient point toward tuberculosis, yet no tubercle bacilli have been found in his sputa. After all, while we may have many symptoms pointing toward tuberculosis, yet, its actual

existence can be always proved by the presence of the tubercle bacillis.

The patient's left side is best let alone, but what can we do for his right side? If I felt certain about subsequent healing, I would insert a drainage tube in this side, but the condition of the left side makes me hesitate. I shall therefore wait awhile. In this case the prognosis is, of course, very unfavorable.

RHEUMATIC NEURITIS.

This woman is forty-two years old; she is married, and has three children. Until five years ago she has always been well, indeed, her general health is good, even now, and she is robustly built. She says that for the last four or five years she has been hoarse, and that she has had severe pains in the knee, and that her legs became swollen. Lately her arms have also swollen, become stiff and given her much pain. The case has been one of rheumatic peri-neuritis. You see that her elbow joints are very stiff. This patient should have daily movements of these limbs so that mobility may be restored. My movements of the arm cause the patient evident pain, and the procedure looks cruel; but in reality it is not cruel, for if this were not done the joints would increase in stiffness, and finally an atrophy of the muscle takes place, leaving the woman with a useless limb. On examining her limbs, I find on the left side of the tibia a thickened lesion. This can only be of a specific origin, and the laryngitis that she complains of, confirms this. Regarding the best treatment to be followed, we will give an ointment composed of equal parts of lanolin, nitrate of mercury, and cosmoline. Internally we will give her iodide of mercury.

THE THERAPY OF DIPHTHERIA.

BY F. LOEFFLER, M. D.,

PROFESSOR OF DISEASES OF CHILDREN, UNIVERSITY OF GRIEFSWALD, GERMANY.

Gentlemen:—The number of remedies which are recommended in the treatment of diphtheria have, during the course of the last few years, become truly legion. Nitrate of silver, mercurial salts, chloride of iron, carbolic acid, chlorine, bromine and iodine, chlorate of potash, permanganate of potash, lime water, turpentine, chinolin, papaiotin, and even yeast, are among the remedies for which their several upholders have claimed superiority; and yet, in the face of all this, there is no one remedy that has merited a general acknowledgment, or found general use.

The majority of physicians have used this or that remedy with good results and have become accustomed to it. By good results I mean that their patients have recovered. Until sooner or later they come across a severe case in which their remedy fails them completely, and they then bestir themselves to find some other curative agent of greater efficacy. The cure of diphtheria still remains a problem of medicine waiting to be solved.

How comes it, we ask ourselves, that the therapy of diphtheria has not yet been placed upon a firm basis? The answer is easily given. Up to the present time an accurate knowledge of the cause of diphtheria is wanting, and, therefore, systematic, scientific and experimental tests of the various remedies recommended in the treatment of this disease are impossible. The only test we have for the value of these various remedies is a statistical one, and in no disease so much as diphtheria, are these statistics so little to be depended upon. Many conscientious physicians frequently report under the name of diphtheria, simple inflammation of the tonsils and pharynx with a slight exudation. Granted that many of the successful cases reported are of the above class, it will at once be appreciated how delusive and misleading such statistics are.

The problem before the investigator is to find the disease germ or cause. This problem has now finally been solved. The morphologically- and biologically-characteristic bacillus, I have found, is the etiological germ of diphtheria.

In this bacillus of diphtheria we have the object upon which the various remedies may be tried. "Not with human beings, but with the parasites in pure cultures should we experiment," said Koch in his address before the Tenth International Medical Congress in Berlin. So, guided by this thought, I for some time studied the actions of various chemicals on the bacillus of diphtheria, and those which I found experimentally successful have also been of great service to me in treating the disease in the human subject, and it gives me pleasure to briefly report the results to you to-day.

The chemical actions of various agents upon the bacillus of diphtheria, have been already studied by many investigators. Their methods of procedure have been varied. D'Espine and de Marignac, placed

4 cubic centigrammes of the solution they wished to test in a test tube, after previous sterilization of the solution, then a portion of a pure culture of the bacilli was added and the contents of the test tube and shaken up. Portions of this culture, thus treated, were then placed in blood serum in order to see whether the germs which had come in contact with the chemical agency were dead or not. One drop of the solution was always placed in the serum with the culture. The contact of the bacillus with the solution was longer than five minutes.

Babes has a different method. In one series of experiments he would allow the coagulated surface of blood serum to come in contact for several minutes with various chemical substances, and then inoculate the surface with diphtheria bacilli. In another series he would first inoculate the serum from a pure culture of the bacilli, and then half an hour later, would wash the surface of the serum with various antiseptic substances for the space of five minutes.

Boer and Behring chose a weakly alkaline beef bouillon, prepared with peptons and salt, and inoculated this with the bacillus. They confirmed, first, in what quantity of bouillon would one gramme of the fluid that was being tested, after the mixture had stood two days, cause a decrease of the bacilli; secondly, in what quantity of freshly inoculated bouillon, and in what quantity of bouillon which had been inoculated for 24 hours, would one gramme of the fluid to be tested cause the death of the bacilli in the culture.

The results obtained by these various investigations differ materially, on account of the varied methods employed. At the outset of my experiments, I endeavored to make them of as practical value as possible, so that the results might be directly applicable to subsequent practice.

In our fight against this microbe in nature, two points are always before us: Frst, to guard against the colonization of the bacillus, in healthy subjects on the intact mucous membranes, and in diseased individuals on the mucous membrane that has not been as yet infected. This colonization can be hindered if we bring the healthy mucous membrane into contact with some substance which will prevent the growth of the bacilli, or better still, which will kill them, as soon as it is brought into contact with them. Of course these substances cannot be of a nature calculated to injure the mucous membrane, or such that even a continued use of them could give rise to toxic or other unpleasant symptoms. Second, the clusters of developed bacilli in the superficial layers of the pseudo-membrane must be killed, so that no spreading of the infection to parts of the mucous membrane, as yet intact, can take place, and also that no living bacillus may be expelled from the patient's mouth, so that the spread of the disease in other persons may be avoided.

In experimental work the bacilli should be placed in a nutritive substance congenial to them, and in which they will increase rapidly, as is the case when they are in the human mucous membrane. The temperature of the culture should also be such as to facilitate the growth of the germs. I have found the following mixture especially favorable to the growth of the bacilli: 4 parts of beef-blood serum, one pint of neutralized bouillon, 1 per cent. of peptone, 1 per cent. of grape sugar, 0.5 per cent. of common salt, at a temperature of 37.5°C.

Ten cubic centimetres of this serum mixture is placed in a test-tube. The tube is held at an angle so as to allow a larger surface to the serum to be exposed to the air until it coagulates. This tube was now inoculated superficially with a fresh culture of the bacillus. In eight hours small colonies could be seen, and in twenty-four hours the whole surface of the serum was covered with a thick layer of the bacilli. Into the freshly inoculated tube, enough of the remedy to be tested was poured to cover the surface of the serum—about 10 to 15 cubic centimetres. The fluid was either immediately poured off again, or else allowed to stay in contact with the serum for ten seconds. The act of gargling can seldom be continued longer than 10 or 30 seconds, and therefore this time was chosen in order to prove the efficacy of the drugs to be employed. The pouring in and out of the fluid did not work off the bacilli.

If a blood-serum culture is allowed to remain undisturbed for several days, it will be found that a thick layer has formed over the serum. This layer corresponds with the colonies of bacilli in the superficial membranous layers in the human subject. After the remedy had been tested upon the superficial culture of the bacilli, it was also tested in cultures several days old, in a similar manner. The time allowed for contact being 20–30 seconds. After the fluid had been poured off, tests were made both from the superficial, and deep layers of the culture.

I discovered, in this way, that while some remedies cause the immediate death of the bacilli in superficial cultures, they have

comparatively little or no effect when the cultures have become thick layers, even when the contact is prolonged, and that in order to produce any effect the remedy had to be used in a concentrated form.

These comparative experiments seem to me, to be of great practical value. They teach us that a prophylactic treatment with weak solutions is not sufficient, but that we must combine these with concentrated applications which will also cause the immediate destruction of the bacilli in the deeper layers.

The remedies which I have tested comprise most of those which have found, or still find, therapeutic application in diphtheria, and also other antiseptics. Some I have subjected to a most careful study, others I have only been able to pay passing attention to.

They are as follows: Bichloride of mercury, cyanide of mercury, metallic mercury, nitrate of silver, chloride of silver dissolved in sub-sulphurate of soda, permanganate of potash, chlorate of potash, saturated lime water, aqueous chlorine solutions, aqueous bromine solutions, aqueous iodine solutions, trichloride of iodine, chlorate of lime solutions, double iodide of potash solutions, alcohol, allyl-alcohol, benzyl-alcohol, ether, chloroform, carbolic acid, salicylic acid, resorcin, hydrochinon, tropæolin, benzol, brenzcatechin, the xyloles, toluol, anisol, phenetol, pseudocumol, oil of turpentine, anilin, thymol, the creosoles, creosol-sulphonic acids, and thirty-eight etheric oils.

The majority of the organic preparations were placed at my disposal by Dr. Limpricht, of our chemical institute, and my thanks are due him.

Bichloride of mercury proved its powerful antiseptic qualities also in killing the tubercle bacillus. Solutions of 1: 10,000 caused immediate sterilization of a superficial culture, and even a solution of 1: 20,000, when brought into contact with the cultures caused the death of nearly all the bacilli, the few remaining ones, however, formed themselves into colonies within a few days. A 1: 2,000 solution, even, when kept in contact with the cultures for twenty seconds, failed to exert any lasting influence upon the deeper layers of the culture. The employment of a 1:1,000 solution caused the disappearance of nearly all the bacilli, and any stronger solution than this caused their complete extermination, even in the deepest layers.

My experiments with the cyanide of mercury were particularly interesting. This drug has been used in the treatment of diphtheria by Hugo Schulz, Erichsen, Rothe, and others. Selldén, of Sweden, has, perhaps, had the most extended experience with it. He has used it in 156 cases of diphtheria, and only lost four, three of which he came too late to relieve.

His treatment consisted in giving a spoonful of the following formula every hour, day and night:

℞

Hydrag cyan.	gramme,	0.02.
Tinct. aconiti	grammes,	2.00.
Mel. crud	"	50.00.
Ag. dest	"	150.00.

M.

For young children 0.1 to 0.4 milligrammes of thecyanide mercury was the dose employed. Then, two to four times during an hour the following gargle was employed:

℞

Hydrag cyan	grammes,	0.04
Ag. menth. pip	"	400.0

Either of these solutions have a strength of 1:10,000. My own experiences have shown that solutions of 1:10,000 exterminate nearly all the germs, although the contact may only be momentary. In solutions of 1:8,000, the sterilization is absolutely complete. The thick cultures were not, however, sterilized even by twenty seconds contact with a 1:1,000 solution, this result being obtainable only when a solution of 1:200 was used. All the same, repeated applications of a 1:1,000 solution will cause subsequent sterilization. Sèlldén's method of using the solutions every fifteen minutes or half hour, would surely hinder the growth of the bacilli. This treatment, however, will not cause a destruction of the bacilli within the membranes. In one case of diphtheria I was able to trace the bacilli in the membranes (by cultures) after the cyanide of mercury solutions had been used for three weeks.

In my opinion preparations of silver promise excellent results. Nitrate of silver in solutions of 1:1,000, when brought in contact with cultures for one to ten seconds, had a decided action. The serum would remain apparently sterile for about twenty-four hours, then, however, colonies would begin to form again. Stronger solutions of 1:150 caused complete destruction of the bacilli. The same solution had no effect upon cultures, even when kept in contact for twenty seconds.

Fresh chloride of silver, dissolved in subsulphurate of soda, was found by Behring to be very destructive to the gonococcus of gonorrhœa in solutions of 1:7,500. Personally I brought four cases of whooping cough to a

speedy termination by inhalations of a 1:10,000 solution of the chloride. Solutions stronger than 1:5,000 are very irritating. In experimenting with this drug on serum infected with the bacillus of diphtheria, I found that ten seconds contact with solutions of strengths varying from 1:600 to 1:4,000, rendered the serum sterile, while the tubes tested with solutions of 1:5,000 to 1:10,000, developed small colonies the subsequent day. But on the third or fourth day, all the tests contained bacilli. In the tube treated with the 1:600 solution, the colonies were very markedly disseminated, but in the weaker solution a coating of the bacilli had formed over the serum. Indeed this drug showed no superiority to nitrate of silver.

Permanganate of potash in a 1 per cent. solution left enough bacilli to form new colonies within the course of a day. A 2 per cent. solution sterilized the surface of the serum. In order to positively destroy cultures within twenty seconds, a 5 per cent. solution was necessary, although the 3 per cent. solution was very active.

Chlorate of potash, 5 per cent., saturated lime water, peroxide of hydrogen 1 per cent., sulphuric acid 1.25 per cent., and lactic acid 1 per cent., were entirely inactive when kept in contact for 10 seconds.

Iodine in aqueous solutions was inactive, but a solution composed of 5 parts of iodine, 10 parts of iodide of potash, and 300 parts water, sterilized cultures in 20 seconds.

Bromine in 1:300 to 1:500 solutions, sterilized the serum in 10 seconds. The bacilli in cultures were only destroyed after a 20 seconds contact with a 2.5 per cent. solution of bromine.

Chlorine water, containing 0.009 gramme of Cl. to the cubic centimeter (1: 112.7) destroyed the bacilli on the serum, even in weaker solutions (1: 1100) in 10 seconds. The first named solution also sterilized cultures in 20 seconds, but the weaker solutions had but little effect.

Although saturated lime water had been proven inactive, saturated solutions of chlorate of lime were most effective. Fifty parts of chlorate of lime were mixed with 200 parts of water. The filtrate destroyed the bacilli on the serum, even when diluted twenty-five times. The cultures, however, were only destroyed by the undiluted filtrate, in 20 seconds. Weaker solutions were almost inactive.

Behring has recently used trichloride of iodine successfully in treating diphtheria in animals, in a 1:1000 solution. Even a 1:2000 solution has a decided action. My own experiments showed that a 1 per cent. solution exterminates the bacilli in cultures in 20 seconds.

Absolute alcohol destroyed nearly all the germs on the serum surface upon momentary contact, and even a 5 per cent. solution was decidedly active. A mixture of alcohol and ether is especially valuable, and the following mixture I have proved to be most serviceable:

℞

Alcohol	50 parts.
Ether	25 parts.
Water	25 parts.

On cultures, however, both alcohol and ether gave negative results.

Allyl-alcohol gave negative results, while benzyl-alcohol sterilized the inoculated serum in 10 seconds completely. Chloroform water was equally as effectual.

Carbolic acid gave negative results in a 1 per cent. solution. A 3 per cent. or 4 per cent. solution will sterilize the inoculated serum. The addition of a 20–40 per cent. of alcohol, greatly intensified the action of a 2 per cent. solution. Cultures were destroyed in 20 seconds by a 5 per cent. solution. The same results could be accomplished by a 3 per cent. solution, with the addition of 30 per cent. of alcohol.

Lysol, which has been recently introduced into commerce, proved very efficacious. Two per cent. solutions sterilized the inoculated serum in 10 seconds. Cultures, however, were not positively sterilized, even by 20 seconds contact with a 5 per cent. solution.

The kresols were but slightly active. Salicylic acid while active in sterilizing serum inoculations, gave negative results in cultures. Two and five per cent. solutions were employed.

The action of the etherial oils was especially interesting. The majority of these strongly odorous oils contain carbo-hydrogen in the form of C^{10} H^{16} and a few contain oxygen. These actions were extremely varied. The majority of them, however, seemed to check the growth of the bacilli, even by their fumes. Anisol in a five per cent. solution of equal parts of ether and alcohol was very effective. Thymol in steam form was inactive, but in a mixture with 20 per cent. of alcohol, it killed all the bacilli upon contact—even in solutions of 1:500. The direct application of watery solutions of anilin, were active on the serum surfaces. Anisol solutions were inactive. Oil of turpentine, even with the addition of 50 per cent. of alcohol, gave negative re-

sults, but the addition of 2 per cent. of carbolic acid rendered it very active.

Metallic mercury in vapor form, was effective in sterilizing serum surfaces.

So much for my experiments, which, however, are far from being complete. Many of the most active agencies, are unfortunately unsuitable for practical use, on account of their toxic qualities.

For prophylactic treatment of persons exposed to diphtheria, gargling every two or three hours, for 5 or 10 seconds with a suitable solution, is recommended. For this purpose, I have found the following very useful: Bichloride of mercury 1 : 10,000, or 1 : 15,000, or better still, cyanide of mercury in a 1 : 8,000 solution, or 1 : 10,000. The taste of the latter preparation is less unpleasant than that of the former. Chloroform water, or thymol 1 : 500 in 20 per cent. of alcohol, are also useful and agreeable. It is of great importance that the gargling should be done properly and thoroughly. In vapor form, oil of orange peel, lemon oil, eucalyptus oil, anisol, phenetol, benzol and toluol are of service. These are best used, according to Feldbausch's method. A small metallic tube, containing absorbent cotton, moistened with the oil, is inserted in each nostril, and the patient is therefore continually breathing the fumes. These tubes should remain in place as long as the patient is in an atmosphere probably victated with the bacilli of diphtheria. The same oils might also be sprayed or vaporized in the sick room with material advantage. In this way the air would be more or less saturated with the fumes, and, certainly, an atmosphere in which orange peel oil, or lemon oil is suspended, is both pleasant and refreshing.

Regarding the treatment of patients actually suffering from this dread disease, I advocate gargling every one or two hours with weak solutions, and gargling every three or four hours with solutions which will positively destroy the bacilli, even in thick cultures. For the latter purpose I have found the following most practicable: Bichloride of mercury, 1 : 1,000; carbolic acid 3 per cent. solution in 30 per cent. of alcohol, finally equal parts of alcohol and oil of turpentine, with 2 per cent. of carbolic acid. Between the appointed hours for gargling, the parts might be painted with a 5 per cent. solution of carbolic acid, 2 per cent. of bromine, 1 per cent. of chlorine, or with a concentrated watery solution of the kresols, especially *o*-kresol and *p*-kresol.

Bichloride of mercury has been used with the most excellent effects, and also the 3 per cent. solution of carbolic acid in 30 per cent. of alcohol. Under the treatment described above the membranes can be proven to be steril within a few days. The general condition of the patient improves rapidly. Gargling with the carbolic acid solution will at first be unpleasant to the patient, but this soon passes off, and the patient soon becomes accustomed to it. It is to be noted that in diphtheritic scarlet fever the above method of treatment is also very successful.

I trust, that in this brief lecture I have been able to set forth clearly the principles of the modern therapy of diphtheria, based on the most recent researches and extensive experience, and that with the advance of medical knowledge this *bête noir* of medicine may lose many of its horrors, and be able to claim but few victims.

COMMUNICATIONS.

THE AFTER-TREATMENT OF CASES OF ABDOMINAL SECTION.

BY CHARLES P. NOBLE, M. D.,
SURGEON IN CHARGE OF KENSINGTON HOSPITAL FOR WOMEN, PHILADELPHIA.[1]

According to Oliver Wendell Holmes, to successfully treat an individual one should begin with the grandfather. The same principle applies to the successful after-treatment of cases of abdominal section. Whenever possible, careful preparatory treatment should be carried out. Nutrition should be improved, where depraved; the emunctories should be made active, especially the bowels and skin. Operation should be rapid, careful and thorough. Diseased, and especially suppurating, structures should receive most careful attention, and unless vital organs, be completely removed. Asepsis in clean operations, and irrigation and drainage in dirty operations are essentials. Under such conditions, unless operations have been made a last resort, or the vital organs of the individual are seriously crippled, proper after-treatment of cases of abdominal section will insure a successful result, quite uniformly.

That which is accomplished by after-treatment in cases of abdominal section is principally of a negative character. The object is to protect the patient from all

[1] Read by title before the Section on Obstetrics and Gynæcology of the American Medical Association, at Washington, D. C.

sources of harm, while nature does her perfect work. The most positive ends accomplished are: to sustain the power of life to enable the patient to pass a crisis; to keep the emunctories active; and to prevent wound secretions from becoming a source of poison.

The after-treatment of typical cases of abdominal section is extremely simple. By typical cases I mean those in which the operation has been done satisfactorily, without special loss of blood, and in whieh the patient goes to bed without marked shock.

The room in which the patient is to remain should be airy, well lighted, and ventilated. The bed, preferably, should be single, and of such a height that the woven wire matress is two feet above the floor. A hair matress is the best. The bed should be made warm during the operation by having hot water cans or bottles placed in it. These should remain about the patient until reaction is complete—care being taken to avoid burning the patient.

Diet.—During the first twenty-four hours nothing should be given. Rinsing the mouth with water will relieve thirst partly. If thirst is excessive, enemas of beef tea, eight ounces or a pint, may be given every four hours. This should relieve systemic thirst; but it will not relieve thirst due to a dry mouth or throat. On the second day one or two drachms of water every halr hour may be given, to be increased or withheld according to the tolerance of the stomach. After thirty-six or forty-eight hours beef tea, one or two drachms, or an equal amount of milk and lime water or soda water, may be given; and increased if well borne, the frequency of administration being decreased. If all goes well, on the fourth or fifth day water practically *ad libitum* may be given. After a week, soft diet may be given, and after two weeks full diet.

Drainage tube, and the abdominal wound.—In my judgment the drainage tube should be used unless there is some special contra-indication. If the drainage is not excessive, nor bleeding going on, it is best to surround the tube with sterilized cotton; with the bandage over all. In this way the tube is protected against infection between dressings. A rope of bichloride-wet gauze should be passed down the tube to Douglass's pouch, and externally into the absorbent cotton. Used in this way most of the fluid poured out into the pelvis will escape by capillary action, and draining the tube will be unnecessary more than twice or three times in twenty-four hours. In this way the tube can be managed by the surgeon. All soiled cotton should be removed at each dressing, and the outside of the tube be kept aseptic by washing with sublimate solution. It is well also to keep the gauze over the wound wet with bichloride solution until the tube is removed. In draining the tube, the rope of gauze is removed, a pledget of aseptic cotton is seized with an aseptic forceps and passed down the tube. This is repeated until all fluid is removed. When the pelvis has been made dry, it is well to pass one pledget saturated with sublimate solution. The wet sublimate gauze drain is next inserted, and the cotton and bandage readjusted. This method of managing the tube has given perfect satisfaction in typical cases.

Where drainage is excessive or hæmorrhage is going on, it is better to use the rubber dam about the tube, having it project through the bandage. In this way it is more accessible for draining. The chances of infection are also greater. In this class of cases the tube must be drained often—even every fifteen or thirty minutes in case of bleeding. The piston syringe may be used to remove fluid; but I have found it unsatisfactory. It will not remove all fluid from Douglass's pouch.

The tube should be removed when the drainage ceases to saturate the gauze rope in the tube, especially if the drainage has become serous. In most cases the tube will remain in from one to three days. When the tube is removed early, the wound should be closed by tying a provisional stitch introduced during the operation. If for any reason it has been necessary to use the tube five or six days or more, it should be elevated from day to day, perhaps a shorter one substituted, and finally a plug of gauze, inserted through the abdominal wound, be used. In this way a sinus can at times be prevented. In such cases the judicious use of sublimate solution, and the peroxide of hydrogen solution within the tube track is of great value. These agents should be on cotton carried down the tube in the grasp of a forceps.

The hands of the surgeon must be made aseptic before each dressing of the tube, and the tube forceps must be kept aseptic. By having the forceps well nickel plated it can be washed before use in sublimate solution. After use it should be carefully washed with soap and water. With a little practice the surgeon can drain the tube with but little use of his fingers. Only the thumb and forefinger of the left hand need come in contact with the cotton or that part of the

tube forceps which passes down the tube. The method employed is as follows: Small rolls of absorbent cotton are wrapped in tissue paper, and sterilized in the steam sterilizer. A roll of cotton partly unwrapped is held by the nurse, the tissue paper serving to keep her finger from touching the cotton. A pledget of cotton is seized by the tube forceps, lightly wrapped about the forceps by the thumb and index finger of the left hand, and then passed down the tube. It may or may not be necessary to steady the tube. The process is repeated until the pelvis is dry. It is manifest that if special care is taken in cleaning one thumb and forefinger that asepsis can be maintained. And this can be done with little expenditure of time.

A satisfactory method of dressing the wound is to use a wet sublimate gauze dressing until the tube is removed, and then to apply a powder consisting of iodoform one part, and boric acid seven parts. The deep sutures should be removed on the seventh or eighth day; at which time the wound should be supported with adhesive straps. Some days later the superficial stitches may be taken out.

The Bladder.—It is best to encourage the patient to void urine. When necessary the catheter must be used. Every care should be taken to avoid catheter cystitis. This is best accomplished by using a glass catheter, having it carefully washed in running water after use, and kept in sublimate solution until needed again. Before the catheter is used the vestibule should be wiped dry with absorbent cotton. Then the catheter, properly lubricated with vaseline, should be introduced, the parts being exposed.

The Bowels.—The bowels should be moved early—the second or third day. I believe that the pain after abdominal section is largely intestinal—due to flatus, or to irregular peristalsis—and that the best way to relieve it, is to open the bowels. The plan of giving a brisk cathartic shortly before operation so as to secure an early evacuation of the bowels, commends itself to my judgment, though I have not employed it. On the second or third day an enema is given; and should this fail, calomel in twelfth-grain doses, every half hour, or concentrated citrate of magnesia solution. (Four ounces equals one pint of the official.) Epsom and rochelle salts have proved too nauseating for my patients.

As an enema the following is used:

℞

Magnesia sulphat	2 ℥	
Ol. terebrinth	½ ℥	
Glycerini	2 ℥	
Aquæ, q. s. ad	4 ℥	M.

This mixture is a very reliable purgative enema.

The bowels should be kept open at least on alternate days throughout the convalescence. Special care should be taken to prevent the accumulation of scabious masses.

General care, especially by the nurse.—During the first few days, or period of thirst and pain, the patient should be encouraged to bear up, and be told that pain is quite the rule after abdominal section. Nervous, fretful patients must be impressed with the fact that nothing will be given that is not thought good for them, and that personal teasing appeals will avail nothing. As a rule, a good *morale* can be thus established. The nurse can do much to promote the comfort of the patient. During the period of thirst the face and hands should be bathed frequently with ice water, or cold water and alcohol, and the mouth should be rinsed frequently with ice water or a weak solution of permanganate of potassium, or of peroxide of hydrogen. Glycerine and ice water will at times relieve "dry mouth," but generally the sweet taste of the glycerine is objectionable. The nurse should be given the rectal tube, and should use it whenever pain from flatus is present.

The bed ought to be kept strictly clean, and the sheets be kept smooth. The draw sheets and the bandages should be changed at least twice daily. The patient's back should be rubbed well with alcohol or soap liniment two or three times daily. She should be allowed to flex the legs and thighs, when the legs can be comfortably supported by placing a small pillow under the knees. Cotton-wool pads or an air cushion should be provided to ease the back. Attention to these details adds much to a patient's comfort.

I believe that it is best to keep patients on their backs for two weeks after abdominal section. During the first week comfort is best attained by avoiding all motion. After eight or ten days the use of the bed rest permits sufficient change in position. After three weeks the patient may be permitted to sit up out of bed. Hernias are best avoided by careful suturing, and by rest until firm union has occurred.

COMPLICATED CASES.

Shock.—Shock is best met by the application of external heat, the use of strychnia,

digitalis, caffeine, and whiskey hypodermically, and of decoction of coffee or beef tea by rectal enema. Within eight hours, thirty minims of the tr. of digitalis, one eighth of a grain of sulphate of strychnia, and two or three grains of the citrate of caffeine may be given. If recovery is not prompt, one-half of a grain of the sulphate of strychnia, and one drachm of tr. of digitalis may be given in twenty-four hours, and enema of beef tea, eight ounces to one pint with whisky one or two ounces may be given every two or four hours. This treatment can be continued for some days. If much blood has been lost, large amounts of fluid will be absorbed from the rectum. A saline solution, also, may be injected into the areolar tissue under the skin. After one or two days, if rectal feeding is necessary, a more nutritious mixture should be substituted. I have used the following:

One egg; milk eight ounces, peptonized; and add whiskey one or two ounces. This quantity can be given by enema every six hours. If rectal feeding is kept up for many days, it is well to wash out the rectum daily with soap suds, so as to remove decomposing material and prevent proctitis.

Vomiting.—Vomiting from ether cures itself. When vomiting continues more than two days, some other cause must be sought. If not excessive, vomiting will usually cease if no fluids are given by the mouth. A mustard plaster over the epigastrium, or a tumbler full of hot water will at times arrest it. If simple means fail, it will be found that the vomiting is due to peritonitis, or to impending obstruction of the bowels. In either case the bowels should be moved at all hazards. This is accomplished best by the use of the purgative enema already noted, given, if necessary, through the rectal tube into the colon. Broken doses of calomel can be given when other purgatives are rejected. Concentrated solution of citrate of magnesia, and Seidlitz powders also can be used. The continued use of these agents usually will open the bowels. Secondary abdominal section for the relief of obstruction should not be undertaken too quickly, as not infrequently the bowels are moved only after repeated efforts; and, moreover, the results of the secondary operation are not encouraging.

Fever.—When fever occurs the bowels should be kept freely open, and the body be sponged freely with cool water. The use of antipyretics is of doubtful value. When to re-open the abdomen for peritonitis, and when to trust to medical measures is a very difficult problem. In general, when the skin is dry, the face flushed, and the pulse full and bounding, secondary operation will be unnecessary; but when the skin is "leaky," the extremities cool, and the pulse rapid and feeble, absorption of septic material is going on and operation is indicated. Unfortunately the result usually is death.

Opium.—The use of opium in any form in typical cases of abdominal section is unnecessary. A little encouragement during the first day or two will enable the patient to stand the pain, and later it is quite bearable. Occasionally morphia is useful when a nervous patient becomes much excited, and cannot otherwise be controlled. I feel convinced that the experience of the past few years has demonstrated the fallacy of the doctrine that opium is curative in peritonitis; and that it finds its legitimate field in abdominal surgery in combating extreme nervous excitation, and in easing the last hours of the dying. Occasionally it may be used temporarily to relieve extreme pain.

Asthenia.—Asthenia must be combated by the systematic use of nutritive enemas with whiskey, together with the administration of such liquid food as the stomach will bear. Champagne can often be given with advantage where other stimulants are rejected. Less can be done by alimentation and medication after abdominal section than after other operations to combat asthenia, because, as a rule, the stomach is not available. The fate of the patient is decided, in general, when the operation is completed.

SOME POINTS IN THE SURGICAL TREATMENT FOR THE RADICAL CURE OF HERNIA.

BY AUGUSTUS P. CLARKE, A. M., M. D.,

CAMBRIDGE, MASS.

One of the most important features in the surgical treatment for the radical cure of hernia is the selection of the proper material for sutures. The sutures in all cases should be aseptic. The wound made by the incision should also be kept aseptic. The operator should have knowledge of the manner in which the sutures have been made, and in order to have such knowledge he should superintend their final preparation. Sutures which have been prepared and are sold in shops should in no event be trusted, notwithstanding the careful manner in which they may seem to have been prepared. No one,

except the surgeon, or his immediate assistants who are to use them, and who have taken occasion to make most careful observation, is at all likely to appreciate this necessity, and to carry out in every detail measures necessary for assuring their preparation in such a manner that they can be relied upon as being surgically clean and perfectly free from germs. Experience has demonstrated that the best material for buried sutures is that obtained solely from animal substances. Cat-gut and tendon, when properly prepared, afford the best material as is yet known for such sutures. Considerable experience is required in chromicising them. If the sutures remain long in the acid they become hard and offer too much resistance to the action of the tissues. The same effect occurs when the quantity of acid is in excess of the due proportion. If, on the contrary, the sutures are not sufficiently chromicised they undergo absorption before complete union of the coapted parts of the wound takes place. Silk ligatures, however carefully prepared, should not, as a rule, be employed in operations on hernia; their substance is not akin to those of the tissues into which they are to be inserted; they are liable to be the medium, either directly or remotely of sepsis, and are rarely, if ever, absorbed. In cases in which they have been used, it has been necessary, for the most part to establish some means of drainage. Such expedients serve to prevent the occurrence of immediate adhesion of the tissues, and to render the line of union weak and yielding, and consequently to afford but little protection against a return of the hernia. The same may be said when horsehair and certain other materials are used for such sutures. It is true that for affording immunity against the recurrence of the hernia the internal ring, may be embossed by the inverting of the sac on its peritoneal surface. This measure may, for the time being, be of some service especially in a case in which a well fitted truss is worn. Such unnatural coaptation of parts is liable, however, to yield before the superincumbent pressure of the abdominal viscera and thus to cause a return, at length, of the hernia. Application of quilled sutures fall far short of accomplishing what is most to be desired, for the adoption of this method of procedure, when silk, or like substance is employed has to be supplemented by some special provision for drainage to the wound. One of the features which I here insist upon to be achieved is that the several different tissues be coapted, each in its proper order and that direct and immediate union be secured without the necessity of having to resort to any method of drainage whatever. Another important feature to be secured in the operation is the restoration of the obliquity or the valve-like form of the inguinal canal, and also of the internal and external abdominal rings. Attention has been called to the importance of this measure, but as yet, I believe, it has not been generally appreciated. This may be effected by free dissection proceeding from the internal ring. In cases in which the tissues have undergone serious changes, or the parts have become distended, deformed, thickened or attenuated much difficulty will be encountered in accomplishing such restoration. Every effort, however, should be made to bring back the canal as near as possible to the typical one, as regards length, diameter and obliquity. In those cases in which the canal has become tortuous, or in which the opening is formed at an undue angle to the parietes of the abdomen, and the parts are not reformed but are left in abnormal condition, the operation undertaken for the radical cure will prove to be of temporary benefit only. Statistics are sometimes offered by different operators to show that certain methods of practice are attended with unusual success. Statistics can be of but little value when the individual operators select cases with the view of showing favorable results of their special methods of operating. In a case in which the sac is to be removed the cord should be freed as high as possible even if the peritoneum has to be impinged upon. The sac should be sewed off by means of aseptic animal sutures; and if the other steps in the operation have been properly taken there will be scarcely any danger of a return of the hernia. There are several advantages in the method of removing the sac. Prominent among them is the greater facility for inspecting its contents and for guarding against the possibility of reducing parts which may be in a state of inflammation. Such a condition of the parts is particularly apt to occur in cases of strangulated hernia, after prolonged taxis or other measures for relief have been undertaken. When the hernia has been properly reduced, the sac should be regarded only as an unnecessary incumbrance. The sac is formed originally from the parietal peritoneum, which frequently becomes distended and thickened. The various changes in its nutrition and vascularity often lead to irritation, inflammation and adhesion, according to circumstances and accidental

conditions. In all cases after opening the sac the surgeon should see whether the circulation returns. If the parts have been too long compressed and there is much danger of sloughing, it will be advisable to resort to resection of the necrosed portions, and not to assume risks of returning them. After opening the sac and relieving the constriction, and before making reduction, the contents of the sac should be carefully examined. If there is evidence of inflammation or an effusion of lymph, free irrigation, with mercuric bichloride should be had recourse to. The sac should then be sowed across at its neck with animal suture and be excised. Different methods of operating for the radical cure of hernia from time to time have been reported. Emphasis is often laid upon the adoption of the most careful antiseptic precautions. A more particular examination of such reports almost invariably reveals the fact that some method of drainage has been employed. The failure on the part of the operator to keep the wound aseptic, must necessarily render the line of union weak, the parts in large measure devoid of vitality, and thus incapable of overcoming the pressure which is the cause of the recurrence of the hernia. This is the reason, no doubt, why so many different methods for the radical cure of hernia have been devised, and why each method of operating, for the most part, undertaken by a different surgeon, so often proves unsatisfactory. In some cases of femoral hernia, excision of the sac is almost imperatively demanded. In those cases in which Macewen's method is adopted, the thickened mass is liable to set up more or less irritation, and to become the source of much inconvenience.

When the sac is removed the ring and canal can be narrowed and sutures can be introduced, in close proximity to the vessels without causing injury or disturbance to the circulation. Another advantage, according to Mr. Poland,[1] is that it allows the closure of the neck of the sac, and thus effectually prevents all hæmorrhage from the wound into the peritoneal cavity. After the sac has been removed the loose folds in the vicinity can be more nearly approximated, the exudation of plastic lymph readily closes the wound effectually from any communication with the abdominal cavity. After the edges of the pillars have been refreshed they may be brought together and retained by aseptic sutures. By this means the canal is reformed but narrowed, and becomes an effectual barrier against the recurrence of hernia. This method is evidently of far more importance than the one which seeks to utilize the sac by invaginating it in the canal, and by converting it into a pad, or fixing it as a boss over the internal ring. Of course in cases of chronic hernia, in which there has been much inflammation, considerable difficulty will be experienced in separating the sac from the surrounding parts. If, however, much care be exercised, and a liberal use of the aseptic sutures be resorted to, the sac can be separated and be removed, to a certain extent without incurring the risks of gangrene, suppuration or inflammation, and the operation will therefore not appear so difficult or dangerous as some writers would lead us to believe. In a recent case in which the hernia is quite small, the sac and hernia may have passed into the abdomen and so have disappeared. These cases may be operated upon without our interfering with the sac. The edges of the pillars should in such cases be refreshed, and approximated by aseptic animal sutures. The other parts are sewed together according to the method already referred to. In congenital cases the cord and sac are frequently found so blended with each other that to separate the one from the other is often most difficult and tedious. In such cases, when there is no appearance of recent lymph, portions of the sac may be left. The remaining fibres for the most part, usually undergo absorption or degeneration. This measure in the operation is quite different from the one which, as said before seeks to plug the canal and internal ring, by means of the retained or inverted sac that is liable to form a painful or hardened mass in connection with the ring and canal. In operations for the cure of hernia, the use of wire sutures is unnecessary, and should not be encouraged. The use of wire sooner or later, becomes the source of inconvenience, if not of serious trouble, and notwithstanding the efforts made in other respects to keep the wound aseptic, their presence is followed by irritation or ulceration, conditions that will necessitate their early removal and thus compromise the usefulness and advantages that should be derived from the surgical measures undertaken. Other methods of treating the sac have been proposed. The cases in which the method by torsion of the sac, can, with any degree of safety, be resorted to are too few for general

[1] John Poland, F. R. C. S. Braithwaite's Ret. Part 98, page 124.

considerations. In every such case the operator of course must be law unto himself

In conclusion I would say that every operation, for the radical cure of hernia, in which the wound is kept strictly aseptic including the employment of thoroughly aseptic animal sutures the results will be most satisfactory, and but little danger is to be apprehended of a return of the hernia. These favorable results may be expected to follow in the cases in which the sac has, as far as possible, been excised, without injury to the cord or other parts. In all cases expected to be successful the operation should be so conducted that no drainage, however simple in its details, should in any way be required. The necessity of observing this principle in operations for the cure of hernia, has been urged by my friend, Dr. H. Q. Marcy. He[1] says the "Coapted surfaces held aseptically at rest, readily tolerate the limited effusion which is utilized in the process of repair. The elimination of the drainage tube, renders the complete closure of an aseptic wound possible, and prevents its further extraneous contamination. Repair ensues as in a subcutaneous wound. The advantages of this method in the treatment of the wound, is the assurance of non-infection. By every method of antiseptic dressing with drainage all surgeons have admitted the great difficulty, and, in children the well nigh impossibility of retaining the wound aseptic." The results of the operations in the hernia cases, occurring in Dr. Marcy's practice, with which I have been connected, and also in those in my own for the past twenty years fully justify the conclusion here reached. By the observance of these principles of aseptics inoperative treatment for the radical cure of hernia, Dr. Marcy has, according to my judgment, attained a success that has scarcely been paralleled.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, May 29, 1891.

The President, John B. Roberts, M. D., in the Chair.

DR. FRANK WOODBURY SUBMITTED A PAPER ON NITROGEN-CONTAINING FOODS AND THEIR RELATIONS TO MORBID STATES.

In connection with the paper of the evening, by Professor Chittenden, upon the "Food-value of Beef-preparations," I have been invited by the Honorable Board of Directors to contribute a few remarks upon "Nitrogen-containing Foods and their Relations to Certain Morbid States." Under the circumstances, it is proper that what I have to say shall be made as brief as possible.

At the outset, our attention is drawn to some fundamental physiological facts which must be kept in mind during the discussion of this subject. The human body is now regarded as a unit composed of an aggregation or community of cells. These anatomical elements differ from each other in some respects, but agree in this: each cell consists of two parts, one living and one non-living, corresponding with cell-nucleus and formed material. What is visible to us is the non-living part, or the formed material; the real living part of the organism is hidden from view. Just as in vegetable tissue, the parts that are permanent and solid are composed of the cell-walls, which may remain long after the essential living part or protoplasm of the wood-cell has dried up and disappeared—in a similar way, in the human subject, the various organs and tissues which give it form and substance are not living; the only part exhibiting vital phenomena is the soft, shapeless, and colorless cell-nucleus, consisting of protoplasm or bioplasm. This living substance, in its chemical composition, resembles the various tissues, varying somewhat according to function, but it contains one essential ingredient which is so characteristic as to confer its name upon the whole class—this element is nitrogen. The celebrated dictum, "Without phosphorus, no thought," might be paraphrased "Without nitrogen, no life." Viewed from the physiological stand-point, the name "Azote," applied to this element by Lavoisier, appears remarkably inappropriate.

As a necessary constituent of the tissues, therefore, nitrogen, in a state of combination, is always present in the human body. Since it is found in considerable quantity and in various forms in the excretions, some two or three hundred grains being discharged daily by the kidneys alone besides what is lost by the intestinal tract and the skin, it is evident that in order to maintain life the supply must be kept up from outside sources. There are two principal directions in which we may look for the supply of nitrogen, (1) the atmospheric air, and (2) the food.

Although the atmospheric air contains about eighty per cent. of nitrogen, we may dismiss this at once as not available, beyond

[1] Treatise on the Radical Cure of Hernia, page 87.

a very limited extent. Experiment has shown that it is not consumed or absorbed in the act of respiration; but a certain amount of air is always swallowed with the food and passes into the stomach, where it may become absorbed by the gastro-intestinal mucous membrane. It is possible that a small quantity is introduced by this channel, especially since it has been demonstrated that a moderate amount of gaseous nitrogen is excreted or exhaled by the skin.

Nitrogen-containing food must, therefore, be regarded as practically the only source of the constant supply of nitrogen which is so essential to the maintenance of the body in a normal condition. In fact, due attention has already been given to this by Liebig, Fick, Wislicenus, Parkes, Pavy, Flint, and others; and the proper relation of the two great divisions of proximate principles of organic origin, the nitrogenized and the non-nitrogenized, have been pretty closely determined. As their results are to be found in all the text-books, I will not refer to them in detail. I may remark, however, in passing, that from the clinical standpoint there appears to be a fallacy underlying all these calculations of dietaries, where food values are expressed in grains of nitrogen and carbon, inasmuch as no allowance is made for waste; the entire quantity ingested is supposed to be digested and assimilated. In practice we know that the feces contain considerable nitrogen, which is not excretory, properly speaking, but represents the excess of consumption, part of the food having escaped digestion. In nursing infants the feces consist largely of undigested casein. Even adults are not able to entirely digest milk, and if so simple an article of food as milk is not completely assimilated, what warrant have we for assuming that the nitrogenized constituents of peas and beans, or of animal tissue, will yield their full equivalent of potential force to the organism? On the contrary, we know it to be a fact, that much food-stuff passes through the alimentary canal without having its proximate principles extracted by the digestive organs and the absorbents.

We may, however, both clinically and by physiological experiment, making due allowance for the personal equation, determine with sufficient exactness the kinds and proportion of different foods required to maintain the body in a normal condition. Proceeding on the same lines, we may discover the effects of an excess, actual or relative, of nitrogen; or, on the other hand, we may ascertain the results of deprivation either partial or complete. We may also be able to see some therapeutic applications of the knowledge thus gained.

From the time of Hippocrates, and even earlier, it has been known that health and disease are largely influenced by food, and that the effects of an animal diet are different from those of a diet exclusively of vegetables. A distinction was even made between leguminous and other forms of vegetable food. It was not until our own day, however, that the practising physician possessed sufficient knowledge of the chemistry of food and of metabolism in health and disease to enable him to direct the diet of his patients upon scientific principles. Following the definition given by Hippocrates, "Medicine consists in addition and subtraction, the addition of the things which are deficient and the subtraction of those things which are redundant; he who practises this is the best physician, but he whose practice is farthest from it is the farthest removed from a knowledge of the art"—we can now prescribe viands suited to a deficiency of nitrogen in the system, or substitute others if there is an excess. To the therapeutic aspect of the subject I will now very briefly ask your attention.

Taking up the latter instance first, we find that a diet poor in nitrogen is useful in the several forms of rheumatism, in gout and lithæmia, and also in recurring attacks of biliousness and bilious headache. Scurvy appears to be caused by an absolute, as well as a relative, excess of nitrogen in the food, and I have seen it caused by the use of an excessive amount of fresh meat among children in an orphan asylum. In its treatment, vegetable food relatively poor in nitrogen is usually employed. Some skin diseases, possibly of lithæmic character, are only to be cured by withholding nitrogenized food. It seems possible that a liberal use of meat in the diet may have some connection with the development of cancer, a disease which appears to be on the increase, as was pointed out by Dr. R. A. Cleemann, of this Society, in his "Address on Hygiene," delivered before the Medical Society of the State of Pennsylvania a few years ago. Dr. W. Mattieu Williams, in a little work on the "Chemistry of Cookery," pointedly directs attention to the large consumption of meat as a cause of various forms of cancer. In families where a hereditary tendency of this kind exists, it is possible that it might be overcome by vegetarianism. Some

nervous affections, notably epilepsy and chorea, are greatly benefited by abstention from meat in the food.

Owing to the writings of Roberts, Fothergill, and others, a causative between a diet rich in nitrogen and some forms of kidney inflammation or degeneration is now generally recognized. And in the treatment of the various forms of Bright's disease, attention to the diet is generally admitted to be of prime importance. There is a widely spread opinion that nitrogenized food is favorable to the occurrence of inflammation, and for this there seems to be a scientific foundation. Parkes has shown that a non-nitrogenized diet causes lowered blood-pressure and diminished arterial tension. Meat, therefore, is ordinarily prohibited under the antiphlogistic treatment, as it was formerly called. In acute inflammations of mucous surfaces, especially in plethoric subjects, the use of animal food is usually forbidden. This should not be applied too strictly, however, for in some cases of subacute or chronic character, a generous and nourishing diet is necessary.

On the other hand, nitrogenized food may be prescribed where there is, from any cause, a deficiency of albuminous principles in the blood, for example in anæmia or chlorosis. In phthisis, this condition is sometimes quite marked and good results have been obtained from the "beef and hot-water" plan of treatment, and also from the use of fresh bullock's blood, or hæmoglobin, which requires less digestive capacity and is more easily assimilated than muscle-tissue.

Children frequently suffer from a deficiency of nitrogen. Where an infant is reared upon condensed milk entirely, the limbs are plump but the tissues are flabby, on account of anæmia. Such children are late in getting their teeth and have little power of resistance against disease. The addition of oat-meal, barley, or rice to the milk will often bring about marked improvement and may prevent the development of rickets. Just here I might stop to point out the fallacious character of some of the arguments based upon the comparative chemical composition of woman's milk and other foods. Leeds found in a number of specimens of woman's milk that the nitrogenous constituents varied from 4.86 to 0.85 per cent. So that one specimen of mother's milk may have six times the amount of albumious material contained in another.[1] This shows the necessity when the child does not thrive at the breast, of examining the milk to find out if it be deficient in nitrogenized constituents. If so, the addition of beef-meal, bovinine or other nitrogen-containing food in an easily assimilable form is advisable.

Eczema in infants, or in sewing woman, is often traceable to a deficiency of nitrogen in the food, and Dr. Rohé, of Baltimore, advises the addition of meat-broth and eggs to the diet as an essential part of the treatment. Similarly, in many syphilitic eruptions upon the skin, in broken-down subjects, good food is a necessary preliminary to any specific treatment. Neurasthenia and atonic dyspepsia, which are so often associated in the same patient, especially if he is at the same time anæmic, can only be relieved by nitrogenized and fatty food, administered in a form easy of assimilation and at comparatively short intervals. On the other hand, in diabetes and in obesity, the diet may be largely nitrogenous, but in this case it is because there is a desire to reduce the carbo-hydrates and not because an excess of nitrogen is particularly sought after.

To return to the children, I wish to call attention to the fact that during the period of growth and development more nitrogen is needed than after the body has assumed its full stature. Hence, school-children should have a due allowance of meat, and should be encouraged to eat oat-meal, corn, beans, peas, and other vegetables known to contain this valuable constituent.

In the foregoing brief *résumé* of an important and interesting subject, I have not made any distinction between the nitrogenous, proximate principles of animal and vegetable origin. Chemically and physiologically they are nearly identical; but practically there are minor differences of palatability, digestibility, and relative utility, which, at present, our limits will not permit us to consider.

[1] Quoted by Starr in his "Hygiene of the Nursery," Philadelphia, 1888.

—Sanitary administration means not only personal comfort and health in the family, but economy to the state and family. Two hundred and fifth thousand lives lost, three million cases of sickness and $20,000,000 in money are traced, in one decade in England alone, to neglect of sanitary care. The sword and musket are terrible ministers of death, but even in armies, where battles kill one person, disease kills at least three.—*Ex.*

Special Correspondence.

London Letter.

LATE SPRING AND THE INFLUENZA—REJECTION OF THE NEW SCHEME OF THE LONDON UNIVERSITY—SIR WALTER FOSTER ON PROFESSIONAL POLITICAL POWERLESSNESS—PROFESSOR GAIRDNER'S LITTLE ANECDOTE.

Spring is late in coming this year. Hail storms have been reported all over the country, varied with snow and sleet, while every now and then a warm, genial day is dovetailed into the midst of this backward season. The cold has swelled the Registrar General's returns in no small degree. In London alone there is an increase of 433 deaths above the average number for the last ten years. The deaths from diseases of the respiratory organs were 584, or 240 in excess of the average; of these 230 were attributed to pneumonia, and 302 to bronchitis. Influenza rose to 148, or 21 in excess of the highest weekly number of deaths in the 1890 outbreak. The death rate for the Metropolis amounted to 24.0 per 1,000. In some of the provincial towns, however, the rate has been brought up to fever pitch. Sheffield, for instance, has shown the following figures for the last three weeks during the influenza epidemic: 57.8, 70.5, 59.3; Leeds, 27.9, 36.1, 48.3; Manchester, 29.8, 35.1, 43.6. A more intimate acquaintance with this mysterious disease is impressing on us the important lesson that fatalities are largely influenced by surrounding insanitary conditions. The smoky atmosphere of Sheffield, together with the dusty workshops, render its inhabitants especially liable to chest affections. The other day a member of the House of Commons solemnly warned the Commissioner of Works that by leaving the windows of the House open he was admitting the influenza. If closed windows would exclude the microbes our difficulty in dealing with those obtrusive vegetable organisms would be materially lessened, but, alas, they are not so easily given the cold shoulder.

The revolutionary spirit of the age seems to have at last invaded the domain of medical education. Two of the most conservative and autocratic of the London powers have lately received a sharp reminder that governing boards cannot for ever ignore the wishes of their constituents. The new scheme of the Senate for providing a degree on "reasonable terms" has been rejected by an overwhelming majority at the meeting of the Convocation of the University of London. The chief opposition has been raised by the provincial schools, which were barely allowed a voice in the proposed future Senate. Then the Council of the College of Surgeons sanctioned the scheme without consulting its members and fellows. At a general meeting of the College a formal censure was passed on the Council for having taken that step, and a further resolution declared it undesirable that that body should have increased power over medical education. Mr. Lawson Tait carried another motion that no amalgamation scheme would be perfect that did not include the Society of Apothecaries, which the Senate had entirely ignored. And thus there is every prospect of a lively struggle. However, there can be no doubt that the student will get his London degree in a not very distant future without being forced to seek it in the Provinces. Some of the journals do not mince matters, but say in so many words that it is the instinct of self-preservation only that has forced the hands of the London Senate. The Scotch newspapers openly acknowledge that the establishment of a teaching London University will be a great blow to their own Universities.

Notwithstanding the attempt of the London Senate and of the London teachers to ignore the Provinces, there is no question that many of our most able men are in the Provinces, although in the natural course of events a goodly number of them are drafted on the Metropolis. One of the first men to call attention to the existence of such a thing as a democracy in the medical profession was a Privincial physician, Sir Walter Foster. In 1883 he made a famous presidential speech before the Birmingham branch of the British Medical Association. In that address he pointed out the political powerlessness of the profession, and started the wave of thought that is now sweeping against various ancient barriers. Sir Walter has lately resigned his appointment as honorary physician to the Birmingham General Hospital, which he has held for upwards of twenty years. Five years since he was elected direct representative on the General Medical Council, and is a member of the House of Commons. On the occasion of his first entering on public life, he says that Sir Andrew Clark wrote him a word of warning to the effect that "Medicine is a jealous mistress," to which reminder he replied that the best antidote was unbroken loyalty. Sir Walter struck a key-note in the further remark that in all his

public work he never had, and hoped he never should lose sight of medicine, for he believed their profession was interwoven with the highest and best legislation and with the future welfare of mankind. This is very much the conclusion that is arrived at by most philosophical thinkers, and may be otherwise expressed in the formula that medicine is one of the most progressive, as it is the most comprehensive, of all professions. After waiting all these centuries, the outside world seems to be waking up to pretty much the same conclusion. Peerages, however, are as yet reserved for such men as soldiers, bankers, brewers, diplomats and successful politicians. Sir James Paget has often been mentioned as our coming peer, but Ministers have not yet made up their minds.

Professor Gairdner has revived an old story that went the round in Edinburgh many years ago, of which it can be said, *Se non e vero 'e ben trevate.* He asks whether it is better to test a harmless remedy by giving it all round, or to adopt the more scientific plan of giving it to one-half of our patients (reserving the other half as a control experiment). The story refers to the former method. "A lady, finding in her prescription something unwonted and as she thought uncanny, turned back to get a further explanation from the Professor, who was by that time fully occupied with someone else. But the man at the door was equal to the occasion. Taking the prescription into his hand he ran it over with a practised eye, inured even to Latin formulæ by long and faithful service in a medical man's house. He returned the paper to the lady and showed her to the door again with the remark," Ou aye, mem, it's a'richt; they're a'gettin' that 'the now." The Professor had been experimenting all round, more or less, with some of the more unwonted metallic salts, such as titaninm, cadmium, tellurium, palladium and so on, most of which turned out to be tonics, with the exception of one, which had the awkward peculiarity of causing the patient to shed abroad such a peculiar and disagreeable perfume or stink (if you will pardon the word) that it had to be forthwith abandoned on that account." As Dr. Gairdner remarks, the anecdote did not detract from the world-wide fame of the Professor in question, nor was it known to have emptied to any extent his over-flowing waiting-room. D. W.

Selected Formulæ.

BLENNORHAGIA.

℞
Creasote.....gtt. x.
Fl. ext. of hamamelis.....
Fl. Ext. of hydrastis canadensis...aa...gtt xv.
Rose Water.....60.0 grammes.
Water.....200.0 "
M.

—*Journal de Méd. de Paris*, May 10, 1891.

TREATMENT OF FISSURED HANDS.

After having washed the hands in tepid water, apply a small quantity of the following solution to the fissures, and let it dry:

℞
Tannin..... 1.0 gramme.
Glycerin..... 20.0 grammes.
Water.....100.0 "
M.

At night, on retiring, the following salve should be applied:

℞
Ext. of ratanhia..... 2.0 grammes.
Lanolin..... .....50 0 grammes.
Vanillin..... 0.10 gramme.
Rose oil..... gtt ij.
M. et. fiat. unguentum.

Gloves should be worn at night.

—*Journal de Méd. de Paris*, May 10, 1891.

WHOOPING COUGH.

Von Genser is said to use the following prescription in the treatment of whooping cough:

℞
Carbolic acid.....1½ grains.
Rectified spirit..... 2 drops.
Tincture of iodine..... 5 drops.
Tincture of belladonna.....10 drops.
Peppermint water..... 2 ounces.
Simple syrup..... 1 dram.

To a child of two years a teaspoonful of this mixture may be given every two hours.

INSOMNIA.

Dr. E. C. Hooved, of Dayton, Ohio, gives an efficient preparation for use in the insomnia following alcoholic excesses, etc., which is permanent, contains no alcohol, is perfectly miscible with water and can be readily prepared by any pharmacist. His formula is as follows:

℞
Chloral hydrat.....
Potass. bromid..... aa ℥iv.
Ex. cannabis ind.....
Ex. hyoscyami..... aa grs. xvj.
Chloroformi..... ℥ij.
Aquæ (bullientis).....ad Oij.

Dissolve the cannabis in the chloroform and add the chloral. Pour the boiling water on this and then add the bromide and the hyoscyamus. When cold filter. A clear amber-colored solution results, con-

taining a dram to the ounce of the chloral and of the bromide, which is in every way as efficient as proprietary preparations like bromidia, chloro-anodyne, etc., and which has the advantage of our knowing just what is in it and how much.—*Lancet and Clinic.*

THE TREATMENT OF HICCOUGH.

The *Gazette Hebdomadaire* gives the following treatment for hiccough. The local treatment is to compress the phrenic nerve and the pneumogastric in the neck by pressure with the index finger, which will often cause immediate cessation of the spasms. The medicinal treatment consists in the administration of a coffee-spoonful of vinegar mixed with a little powdered sugar, or the following formula may be used:

℞

Subnitrate of bismuth.....45 grains.
Oxide of zinc
Valerianate of zinc } of each...1 drachm.
Powdered calumba
Powdered Opium.....½ grain.
Essence of anise, a sufficient quantity.

Mix thoroughly, and give half a teaspoonful of this powder in a wineglassful of sweetened water.

TREATMENT OF PARASITIC DYSENTERY AND OXYURUS.

C. Minerbi employs naphthalin (*Médecine Moderne*) suppositories and oily enemata, the suppositories being made as follows:

℞

Naphthalin
Butyr. cacao.....aa 3ijss.

M.

When the ulcers are seated higher up than can be reached by suppositories, the author has recourse to oily enemata:

℞

Naphthalin.....gr. lxxv.
Ol. olivarum.....3v.

M.

At the beginning of the dysentery the injections cannot be held much longer than a half-hour, on account of the tenesmus. They should be repeated three or four times every twenty-four hours at this period. Later, the patients succeed in retaining them longer and longer so as to last five or six hours, or even be absorbed. Besides this the enemata do not bring about constipation.

For oxyurus the same method has been successfully employed, children infested with this parasite being cured in less than a week. The formula employed is as follows:

℞

Naphthalin.....gr. xv-gr. vxij.
Ol. olivarum.....3x-3xv.

M.
Sig. For one injection.

For an adult the enema should be made stronger such as:

℞

Naphthalin.....gr. lxxv-3jss.
Ol. olivarum.....3xv-3xx.

M.
Sig. For one injection.

COCAINE IN ASTHMA.

C. R. D. Sylva reports a case in which very severe attacks of asthma were in a few minutes entirely relieved by the following subcutaneous injection:

℞

Cocaine hydrochlor } ....aa ¼ gr.
Morph. sulph. }
Aquæ destil.....q. s. M.

—*Ind. Med. Gaz.*

ALOPECIA FOLLOWING CONTINUED FEVERS.

℞

Ext. jaborandi f.....
Tr. cantharidis..... aa ℥ ss.
Glycerine .....
Olei vaselin..... aa ℥ i.

M. Sig.—Apply locally with a sponge at night.

—*Barthlow in Col. and Clin. Rec.*

PRESCRIPTION FOR ECZEMA OF THE ANUS AND GENITAL ORGANS.

Lustgarten advises, in *La Semaine Médicale*, the following ointment:

℞

Oleate of cocaine .....15 to 30 grains.
Lanolin.....1 ounce and 2 drachms.
Olive oil.....2½ drachms.

Use externally.

Make an application of this ointment twice daily, and after each application powder the affected part with any absorbent powder whatever. Warm soap baths will aid in curing the disease. In pruritus ani, suppositories of cocaine can be employed with advantage.

TREATMENT OF ERYTHEMA OF THE EYELID.

Brocq, in the *Revue d' Ophthalmologie*, states that he employs the following ointment in the treatment of erythema and swelling of the eyelids:

℞

Salicylic acid..... ..... 7 grains.
Lactic acid..... 7 "
Resorcin..... ..10 "
Oxide of zinc.....30 "
Pure vaseline..... 5 drams.

Care should be taken that none of the ointment enters the eye.

In other cases the following ointment may be applied:

℞

Salicylic acid.....15 grains.
Pyrogallic acid.....30 grains.
Vaseline. .....15 drams.

This treatment is to be applied at night, and it may be alternated with that containing resorcin just given.—*L' Union Médicale.*

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

TRACHEOTOMY VERSUS INTUBATION.

Tracheotomy and intubation are the two recognized surgical procedures for the relief of tracheal and laryngeal obstruction. One or the other of these operations may be required to relieve the dyspnœa dependent upon membranous laryngitis or diphtheritic laryngitis, growths in the larynx or trachea, growths exterior to these organs causing pressure upon them, œdema of the mucous membrane of the larynx or trachea from inflammation, from the inhalation of irritating gases, from the swallowing of corrosive liquids or from burns or scalds, etc.

For many years, tracheotomy had been the only method employed for surgical interference in these cases. In 1880, Dr. Joseph O'Dwyer, of New York, began a series of experiments which, later on, resulted in the perfection of the operation, now known as intubation. It is certainly an ingenious plan and the contrivances for its performance reflect more than ordinary credit on the inventor and investigator.

Regarding the utility of intubation in general practice, it is the object of this paper to discuss, as well as to show the relative value of the operation as compared with that of tracheotomy.

The advocates of intubation, claim that on account of the simplicity of the operation and the avoidance of the use of the knife, it is the procedure that commends itself most highly to the profession and is the operation that will be allowed most readily by the laity.

True, the operation of intubation is a knifeless procedure, and so far as the general public are concerned, is the one they would select, if the choice were theirs. But, on the other hand, is intubation a simple surgical operation? If it is, then it certainly, in this respect, possesses a decided advantage over tracheotomy. Unfortunately such is not the case, for not only is the operation, as well as the removal and replacement of the tube very difficult procedures, but the

requisite manipulations require a degree of manual dexterity which the average physician is not apt to acquire, who is called upon to practice the operation only on rare occasions.

Furthermore, the re-introduction of the tube, which is a frequent necessity in cases of intubation, is a source of constant annoyance to the patient, occasioning all the fright of the primary operation, together with nervous and physical exhaustion of the child, induced by its alarmed condition and attending struggles. The exhaustion hereby produced, is, in diptheria, above all things, to be avoided.

Among other complications, accompanying or following the operation, may be named: 1. Loosened false membrane may become wedged in the lower end of the tube, and require its instant removal; or worse still, the membrane may be forced downward by the entering tube into the trachea, and, before it can be coughed up or the passage cleared for the patient to breath, cyanosis may develop, respirations cease and death ensues; no time being afforded for the performance of tracheotomy. 2. Owing to the presence of tenacious or ropy mucus, or from the formation of loose membrane—which the child, in its weakened condition, is not able to expectorate—the tube may require removal at any time, and in the absence of the physician and the inability of other persons to remove it, symptoms of an alarming nature may occur. 3. The liability of liquids finding their way into the air passages, and pneumonia following as a result. This is a source of great danger, which is to be kept in sight, especially as an inordinate desire for fluids exists in these cases, the result, not of actual thirst but of uncomfortable sensations caused by the presence of the tube. 4. In a certain few cases (estimated to be about one per cent.), ulceration from pressure of the tube and alterations in speech have been met with; the aphonia being partial or complete, but always amenable to treatment. 5. The danger of the tube becoming loosened during a paroxism of coughing is by no means slight. In such a case, it may become lodged in the œsophagus, or else be gotten out through the mouth, if prompt assistance be rendered. In either instance, the child is in a serious condition, especially in the absence of a medical attendant. The larynx, after such an accident, is liable to behave in one of two ways: either the swollen tissues will occlude the entrance of air, or the relaxed vocal cords will fall together and give rise to immediate severe dyspnœa.

From the above observations we are forced to admit that intubation of the larynx is by no means a simple surgical procedure, nor is it an operation devoid of dangers. These facts being accepted, our next step is to show the relative value of intubation and tracheotomy, and to prove wherein one is superior to the other.

In the operation of tracheotomy, the physician is able to see his work and to meet such complications as may arise in a cool and calm manner—for he is not working in the dark. Such is not the case when intubation is performed. There the surgeon is obliged to work unaided by sight, trusting entirely to his sense of touch.

In tracheotomy the pain is momentary and the subsequent treatment of the tube can safely be entrusted to the nurse or the child's attendant. Not only so, but the operation once performed, is finished, and the patient is not harassed by subsequent surgery. Unfortunately, intubation is not attended with these results. The presence of the tube may at any moment become a source of danger, and in the absence of the physician, even a cause of death. The operation itself is often as trying to the patient as that of tracheotomy, and the subsequent removal and reintroduction of the tube—which is of daily necessity, at least—repeats all of the suffering, be it mental or physical, of the primary procedure. Furthermore, the operation of intubation has frequently to be followed by that of tracheotomy.

Finally, in spite of the fact that tracheotomy is regarded as one of the most difficult of surgical procedures, it is our belief that any country practitioner, who possesses some

acquaintance with anatomy, and has a cool head together with some surgical experience, can perform it.

Glancing for a moment at the statistics showing the relative mortality and recoveries of the operations, we are confronted with the fact that they are largely in favor of intubation. But when we consider that intubation is frequently followed by tracheotomy, and that the latter operation is often performed when the patient is in a moribund condition, the apparent discrepancy in the results of the operations is explained.

In conclusion, we think we can draw the following deductions:

1. That in cases of equal gravity, tracheotomy is not, in itself, a cause of greater fatality than intubation.

2. That the operation of tracheotomy involves less suffering to the patient, because once performed, it is done, and the patient is not annoyed by subsequent steps, as in intubation, which operation in its repetition, involves all of the harassment of the primary procedure.

3. After a tracheotomy, the patient usually falls into a quiet slumber; such is not the case when intubation has been done. Clearly showing that the presence of the tube, inserted between the vocal cords and into the larynx, is a cause of greater and more prolonged irritation than is the case in tracheotomy, where the tube is placed lower down into the trachea.

4. Intubation involves a great risk of foreign bodies, liquids, etc., entering the trachea and setting up a pneumonia.

5. In tracheotomy, the subsequent cleansing of the inner tube, can safely be intrusted to the nurse. In intubation, the doctor alone can give the tube its needed attention.

6. The physician who is able to perform properly an operation of intubation, is just as competent to do a tracheotomy, and in the latter case, with less liability of dangerous sequelæ following.

Hydrogen peroxide made into a paste with chalk or cuttle-fish bone is an efficient agent for whitening discolored teeth.

CORRESPONDENCE.

BERMUDA.

EDITOR OF THE MEDICAL AND SURGICAL REPORTER.—

Dear Sir:—Seven hundred miles from New York lies a land quite unfamiliar to most Americans, yet having within its borders much to charm, and above all, possessing in large degree that which nature has provided to restore those giving way before our over-active life.

Bermudians assert their climate the most equable in the world, and temperature tables, high and low, largely support this claim, the record for 1889–1890, as compared with several other winter resorts, being:

	Nov.	*Dec.*	*Jan.*	*Feb.*	*Mar.*	*Apr.*
Bermuda	77--62	73--58	71--50	72--49	72--50	74--56
Los Angeles	82--43	68--40	67--34	81--35	81--40	94--42
San Diego	83--46	69--40	66--35	77--38	74--41	85--45
Jacksonville	86--30	80--35	80--40	83--44	85--27	88--47
St. Augustine	84--35	76--43	79--43	81--45	87--28	86--51

The present season has been: Nov., 79–56; Dec., 73–51; Jan., 71–48; Feb., 74–52; Mar., 72–49. As a rule, November, April and May are most agreeable. During December, January and February last, however, the weather most of the time was charming. March is the worst month, when east winds, low barometer and thermometer and frequent showers are apt to prevail. The porous soil admits of outings soon after a heavy rain. As in England, mornings often betoken a stormy day, but the clouds roll by to a beautiful afternoon. July and August for the "outside barbarian" are not to his liking; and September, with its sultry breezeless days, is most oppressive of all. May and June, as regards climatic conditions and the floral beauty of forest and field, offer special attractions; but fashion at present decrees that during March the full tide of travel shall crowd steamers, hotels and boarding-houses to discomfort. The highest pleasure in these sunny isles will never be found till this senseless fad has had its day.

These islands, once called the Isle of Devils, were discovered in 1515 by Juan Bermudez, and, though many in number, only the five largest are tenanted. Their shape is that of a shepherd's crook; their area about twenty-one miles. They form a ring of coral reefs round a lagoon, the coral structure resting on a sub-marine mountain of volcanic origin—a lonely cone rising three miles from the ocean bed. Until the placing, last summer, of the cable to Halifax, they formed the most isolated spot on the globe, save, possibly, St. Helena. The population

is 16,000, of which three-fifths are black. Hamilton, the capital and leading town, contains 2,000.

The soil is red and rich—composed of peroxide of iron, alumina, silica and earthly phosphates—and, fertilized, is largely productive. The climate being semi-tropical, vegetables and southerly fruit abound. The former comprise all known in our northern gardens, the onion, of course, leading the list. This typifies the acme point of Bermudian excellence, according to Mark Twain, who declares that the fond Bermudian father, sending his noble scion of a noble sire out to battle the world, breathes a parental blessing, and—as tending towards the highest attainable—this parting injunction: "My son, be an onion!"

The houses in Bermuda are, almost without exception, built of coral, white, and so soft that it can be cut and trimmed by saw and chisel, but promptly hardens on exposure. The roofs are thin slates of the same material. These are annually whitewashed, and, rising mid their emerald surroundings—the islands are perennially green—give a charm to the landscape that must be seen to be appreciated. Each dwelling is required by law to be provided with a tank for rain water taken from the roof, which, with the yearly whitening, insures its purity. There are wells, but the water is too blackish to drink. Last year the supply was largely increased by several artesion wells, the water of which is good.

Of fruits, bananas, oranges, lemons and the paw-paw are most abundant. The bananas are of the yellow sort—sweet—but too small to compete in northern markets with those from more southern climes. The oranges and lemons are too inferior for use. The paw-paw is essentially a local delicacy, mostly used by the natives. There are no apples or peaches. There is a cherry, but it is not toothsome. On a former visit, in January, strawberries were abundant and good. Since then their culture has largely fallen off; but it has been thought that, with selected plants, extra care and added market facilities—quicker transit and cooling rooms on the steamers—they might be made an export of no little value. So, too, might the valleys and sheltered places produce figs, pineapples and other fruit; but the Bermudian planter seems to let his ambition tend mainly to potatoes and onions.

The cedar is *the* tree of Bermuda; but the palm-tree, the palmetto and bamboo rearing their stately heads, vary forest and field. Flowers bloom the year round, roses—some of which are found only here—the most. The oleander and geranium, fullest in May and June, hedge the highways. Lilies, at best in April, fill whole fields, making a picture beautiful and unique. The varied floral adornings, and so abundant, form one of Bermuda's greatest charms.

The health of these islands is almost always good. A healthy October presages a healthful winter. There has been no epidemic since 1853, when yellow fever made havoc—sparing neither sex, state nor condition. A sort of pessimistic writer hinted last summer that enteric fever was rather rife, but it was not true. The greatest mortality is under five, and, among the blacks, largely due to neglect. Long lives, 85 to 95, are not uncommon. There are nine resident registered medical men, all graduates of American colleges except two—Dr. Eldon Harvey, M.R.C.S., L.R.C.P., England, and Ettore Sarzana, M.D., Italy, L.S.A., London. There are ten army and five naval surgeons. There is a branch of the British Medical Association, before which the writer, by invitation, had the honor of making an address on narcotic inebriety. A general board of health is composed of the governor and council—the latter, nine, leading non-professional men of the colony. There are two health officers—a post-surgeon at St. George and a local physician at Hamilton; services paid by fees. Two coroners, non-medical men, are paid in the same way. Gaol surgeons at these places get $200 per year. Quarantine regulations are careful and complete.

The insane asylum here is a large building, once intended for college purposes, and contains forty beds. The attending physician is Dr. Hinson, the senior practitioner of Bermuda—salary $1,100.

Through the effort of Dr. Harvey, a handsome hospital cottage has been erected about half a mile from Hamilton. It may prove of much value should contagious disease occur among visitors. Nine-tenths of its cost was given by Americans. Great credit is due to Dr. Harvey for this good work. A new army hospital is being constructed at Camp Prospect, the central military post, two miles from town. It will admit one hundred.

The leading death cause is tuberculosis, mainly among the blacks. Forty cases occurred year before last; 40 last year. The mortuary report for 1890 included, debility 25, enteric fever 20, heart disease 20, whooping-cough 20, diarrhœa 18, pneumonia 15, old age 14, tetanus 10, still-births 28. There is much rum drinking, but little open drunk-

enness. There were two deaths each from alcoholism in 1889 and 1890.

Births and deaths are fully recorded. The former lead, making an annual increase in population—last year 241. Death certificates are not prerequisite for burial, but must be presented within a fortnight. The illegitimate births are many—during the last decade 953, of which 909 were black. The number last year was 84, the lowest, save once, since registration was adopted, twenty-five years ago—a hopeful index of bettering morals among them. There are six drug stores—one of them at St. George, twelve miles from Hamilton. Druggists are not examined. Any one, on payment of five shillings, can set up shop.

Climate has been thought, hitherto, the leading remedial factor for invalids in Bermuda, but a new Richard has lately entered the field. A band of Kickapoo Indians (?), made up of half-breeds and others from Quackland and elsewhere, swooped on the islands — an unheard-of visitation — some weeks ago. They pitched their tent hard by the town, posted walls and waste places with pictures of the noble red man in various attitudes of samaritan ministration, "laid low" during the day, and at night, by dint of so-called music, tight-rope antics, acrobatic acts, juggling feats and other "fetching" performances, drew the dusky natives in droves, and actually depleted them of $1,500 in one week—a big amount for those no better off in the world's wares than they are. Having dearthed this field, they stole away to St. George, worked that place for all it was worth—to them—and are now at Somerset for a season, after which they purpose a parting raid on Hamilton, and then set sail for the land of wooden nutmegs, whence they came.

An event so rare as to be the only one in the annals of Bermuda, was the recent trial—on an indictment for manslaughter for the alleged killing of a patient by overdosing with opium and belladonna—of one of the two colored physicians. The facts, as brought out at the inquest and trial, were that the doctor was called to a middle-aged colored man, ill with painful bowel obstruction, and prescribed:

℞

Tincti. opii.....
" belladon.....
Spts. chloroform.....
" ammon aromat.....aa gtt.v.

to each teaspoonful, with instructions to repeat every ten minutes till relieved. This was repeated, more or less regularly, and—to shorten the story—in thirty-six hours the man was narcotized, and, in forty-eight, gathered to his fathers. The doctor, a very intelligent-looking fellow, graduate of a western medical college, frankly stated in his certificate that death was due to bowel obstruction and over-dosing with opium; but the gossips got in some fine work, a hue went up, and an indictment followed. He plead not guilty. Expert evidence for the prosecution was given. A question by a juror disclosed the fact—vital for the defence and made the most of by his counsel—that the teaspoon used held nearly double the usual amount. There was little question that the man died from narcotic poisoning, but the evidence failed to prove criminal lack of medical care. The trial lasted five days. The jury was out twenty minutes. The doctor was acquitted.

It seems to us strange more medical men do not visit Bermuda. We have noted less than a dozen, and most of these from Brooklyn. Physicians might well set their patients an example in this regard, and by so doing induce many more to spend an outing here. The fact is few realize that less than sixty hours from New York is a lovely land, an evergreen isle, where roses bloom the year round out of doors, and the high tide of rose time is December; where malaria never comes; where frost and the white mantle of winter are unknown; and where the sleep-giving, health-bringing breezes, the panoramic beauty of sea and shore, and the quiet, restful life, combine to make halcyon days.

For insomnia, Bermuda is unique to do good. It is not the place for consumptives, nor for one far advanced in any wasting disease. It is a happy land for the neuralgic, and those coming back to health from acute disease. For the weary and worn, for the tired pilgrim along any line—be it brain or brawn—it is indeed a Mecca to which he may go with high hope of getting rest and relief.

Bermuda is, too, good for those not ill. Let the busy American doctor take a fortnight off, and a ten-days sojourn in these sun-lit isles, and our word for it, if conditions favor, he will lay in a stock of happy memories for many days to come.

The writer has been presenting a series of letters from Bermuda in a Brooklyn daily. One object was to induce those who might read them to visit this favored land. He will be glad to tell any one what he knows about this charming resort, and if, in so

doing, more of his confréres shall share in the pleasures he has enjoyed, he will be content.

J. B. Mattison, M. D.

Editor of the Medical and Surgical Reporter.—

My Dear Doctor:—I have been suffering the past fall and winter with gall-stone colic, the attacks coming on every three or four weeks. I could get relief from the usual remedies such as morphine, belladonna, chloroform, etc., but what I wanted to find was a remedy to prevent the formation of the gall-stones. I was advised by my old friend Dr. Job Bell, of Tennessee, to take gum guaiac and whiskey in the following proportions: Gum guaiac ℥ii, whiskey, Oj, and take one tablespoonful in water after each meal. I commenced taking the prescription and the result is I have gone five weeks longer without having an attack than I have since my first attack about six months ago. Before taking the remedy I would have a spell of billious colic every four weeks at the furthest, but usually every three weeks. It has now been nine weeks since the last attack.

The remedy improves the appetite, keeps the bowels open, and produces a copious flow of bile each day.

Dr. Bell is very enthusiastic about the merits of this drug. He says he has treated many cases in this way and has had excellent results.

The Dr. thinks it best to give the guaiac in whiskey as whiskey is less objectionable than alcohol for obvious reasons.

I write this feeling confident it will be of great use to the profession, and a boon to those who are suffering with this fearful malady.

Very truly,

J. F. Bagwell, M. D.

Book Reviews.

A TEXT BOOK OF PRACTICAL THERAPEUTICS, WITH ESPECIAL RFFERENCE TO THE APPLICATION OF REMEDIAL MEASURES TO DISEASES AND THEIR EMPLOYMENT UPON A RATIONAL BASIS. Second edition. Enlarged and revised. By Hobart Amory Hare, M. D., B. Sc. Philadelphia, Lea Brothers & Co., 1891.

The evidence of the popularity of this work is shown by the fact that the first edition was exhausted within six months of its publication. Its value as a *Practical* "Therapeutics" is demonstrated by its adoption as a text book in a number of medical schools.

The present volume consists of 658 pages, and is divided into four parts. Part one is devoted to general therapeutic considerations, such as modes of administering drugs, dosage, idiosyncrasy, absorption of drugs and their duration of action, incompatibility, etc.

Part two takes up the consideration of the drugs of the pharmacopœia (U. S.), and such other remedies as are in general use, or are entitled to notice in a work on general therapeutics. Each agent is treated in alphabetical order, separately, and is discussed first, by a brief description of the drug, followed by an account of its mode of action, its application in disease, the methods of administration, and when occasion requires, the contra-indication to its employment. In the case of the more powerful drugs, the toxicological symptoms and the treatment are given. Excellent tables are appended in some instances as a means of differential diagnosis between the actions of certain remedies and the symptoms of particular diseases, as in the article on alcohol, in which three tables are given differentiating alcoholism from opium poisoning, apoplexy, and the general paralysis of the insane. In this section (page 72), the author directs particular attention to the prevalent abuse, or rather misuse, of arsenic in the treatment of skin diseases—no distinction usually being made by the general practitioner between the *moist* and the *dry* varieties of these affections. It is only in the latter cases that the drug is indicated or does good. Arsenic is contraindicated in lesions associated with much proliferation of new cells and the exudation of serum, etc.

An important detail is not mentioned in the article on cocaine, in the description of its use in minor purgery as a local anæsthetic (p. 141). It is not alone necessary to employ a ligature in such instances, in order to control the circulation and to prevent undue absorption of the drug, but it is equally important *to allow free bleeding at the completion of the operation, but before the sutures are tied*, so that any excess of the cocaine may be washed out. The neglect of this point is a frequent cause of the untoward results, so often reported as following the employment of the drug in surgical practice to produce local anæsthesia.

In the respective articles, ergot (page 159) and eucalyptus (p. 166), notice might have been made of the therapeutic value of the first drug in the relief of eneuris, and in the second instance, of the relief afforded patients

suffering from sub-acute or chronic bronchitis, pharyngitis, etc., by the employment of the oil of eucalyptus as an inhalation.

Part third treats of remedial measures other than drugs, and also includes a valuable addition in the shape of an article on "Foods for the sick."

The fourth part consists of articles upon the treatment of diseases and symptoms; a table of doses and remedies; tables of relative weights and measures in the metric and apothecaries' systems; an index of drugs and remedial measures, and an index of diseases and remedies.

With this brief summary of Dr. Hare's book, we would close our remarks by restating a fact mentioned in the earlier part of this notice—that the work is essentially "*practical*" in every particular and, therefore, can be heartily recommended as a book for the student and general practitioner.

DIABETES: ITS CAUSES, SYMPTOMS, AND TREATMENT. By Charles W. Purdy, M. D. Philadelphia and London: F. A. Davis, 1890, pp. 184.

Among the monographs which are destined to uphold the dignity and repute of the medical profession in America, the work of Dr. Purdy must be granted a prominent position. Its excellence does not depend simply upon the practical and concise form of presentation of the subject, but as well upon the value of the original matter which is contained in the book.

The first consideration which excites the attention of the reader is the prominence accorded the features of the disease and its climatological study in the United States, the observations in these relations being based upon the personal experiences of the writer and upon data obtained from the census of 1880 of this country. From the statistics detailed Dr. Purdy concludes that there is a definite factor exerted upon the ætiology of this affection by the influence of climatic circumstances. Diabetes mellitus reaches its highest proportion in those parts of the country in which there is the lowest mean temperature, combined with a low barometric registration; on the contrary, its least proportion coincides with those portions of the country where the mean temperature is highest and the barometer is relatively high. A rare atmosphere, in Dr. Purdy's opinion, is favorable to the establishment and perpetuation of a glycosuria, in that it directly contributes to a lowered possibility of oxidation. On the contrary, the marked barometric pressure induced by dampness of the air is not without some deleterious influence, the conditions of excellence demanding a warm or moderate climate with high barometric registration and dry air. In the United States the highest mortality from diabetes is reached in the north-eastern hills and plateaus, especially in the state of Vermont, in which region the mean temperature is from 35° to 45° F. and the mean elevation 1500 feet; the lowest mortality is shown to be found (and from these studies this region is regarded as the most favorable climate possessed by the United States) in the South Atlantic coast, the southern interior plateau and the south-west central region. This range embraces, in part or in whole, the states of North Carolina, South Carolina, Georgia, Alabama, Mississippi, Louisiana, Arkansas and Texas. This region, in Dr. Purdy's view, furnishes, not only climatologically but also in the constant supply of foods suitable for the diabetic, the most striking advantages for the treatment of the disease to be found in any part of the inhabited globe.

The author looks upon diabetes mellitus as essentially a disturbance of the glycogenic function of the liver, by which there occurs an arrest of the transformation of certain forms of the food (the ultimate transformation being probably into fats) whereby these substances, because of their non-assimilability, are thrown out of the body in an intermediate form, sugar. In this hepatic disturbance there occurs a hyperæmic condition of the liver and a more or less engorged condition of the chylo-poietic viscera. Recently ascertained facts point also to an influence exerted by disturbance of the pancreatic function, in connection, however, with the hepatic disturbance; further, pathological states of certain portions of the central nervous system which preside over the hepatic vascular area may induce phenomenon of glycosuria.

Among the causes of the disease the author places heredity in a prominent position. Among the instances narrated under this head it is interesting to note, in view of the recent query of Schmitz as to the possibly infectious nature of this disease, the occurrence of diabetes in the father and the mother of one of the writer's cases. Richard Schmitz in the past year has discussed the possible transmission of diabetes mellitus from husband to wife or *vice versa*, and has pointed out the not infrequent occurrence of such instances. Besides heredity, as causative influences the author mentions the greater frequency of the disease in the male

sex, in the middle portions of life, the influence of over-eating, climate, various diseased conditions, and mental emotions.

In treating of the symptoms of the affection, the various phenomena are taken up as presented by the different systems of the body. Dr. Purdy calls attention to a very valuable modification of Fehling's reagent for the detection of urinary sugar by which he is enabled to keep the cupric sulphate solution indefinitely without change, and which consists briefly in the substitution of potassic or ammonium hydrate for the bitartrate in Fehling's solution and the addition of glycerine to the solution.

The work is particularly complete in the treatment of the disease. Dr. Purdy condemns all the common diabetic breads and relies upon ordinary home-made wheaten bread, preferring to diminish its quantity rather than to replace it by an unlimited amount of an article which may, and in most cases probably does contain a greater proportion of starch than the patient's usual home diet. He refuses his patients such beverages as tea and coffee, finding from experience that they contain a notable amount of sugar; and permits only the following list of drinks—water (including all mineral waters) Rhine wine, California Rislings and Chablis, New York and Ohio Catawbas, Rudai Imperial, Schreiber's "diatetic wine," whisky and gin. Of medicinal agents, arsenic, jambul, iodoform, ergot, the alkalies and opium are regarded favorably; antipyrin with others of its class is severly condemned.

Following the general consideration of the disease there occurs a section of clinical cases, detailed for the purpose of illustration of the statements made in the previous portions of the book. Finally, there is a chapter upon diabetes insipidus, which is more briefly considered and serves as a background for the more important disease, to the literature of which the author has in this work contributed a really valuable addition.

TREATMENT OF ERYSIPELAS.

Dr. Koch treated numerous cases of erysipelas with the following ointment:

℞

Creolin	ʒ i.
Iodoform	ʒ iii.
Lanolin	ʒ i.

This ointment is spread as an even, smooth layer over the affected skin and its surroundings, on an area of at least two to three inches to the outside of the inflamed parts. The whole is covered by a piece of mackintosh.

PERISCOPE.

THERAPEUTICS.

ARSENITE OF COPPER IN DIARRHŒA.

Dr. F. Hinz, in the *Journal de Méd. de Paris*, May 3, 1891, strongly advocates the use of arsenite of copper in diarrhœa. He prescribes the drug in the following formula:

℞

Arsenite of copper	gramme 0.05.
Water	grammes 90.0.

M. et sig. Half a teaspoonful every hour.

During the next day the remedy is only given four times. Recovery is usually rapid.

[We strongly suspect that Dr. Hinz has taken his idea from Dr. John Aulde, of Philadelphia, the latter gentleman having used the drug similarly for some time and having written extensively on the subject. Ed. Reporter.]

ACETANILID IN THE TREATMENT OF HARD AND SOFT ULCERATING CHANCRES.

Basilvitch, in the *Journal de Méd. de Paris*, May 10, 1891, reports three cases of ulcerating chancres—one hard, in a female, and two soft, in males—that he successfully treated with local applications of acetanilid. Healing was both rapid and complete. The drug's action was equally as good, if not better, than that of iodoform in similar cases. It possesses, also, two material advantages over iodoform, first, it is inodorous, second, it is comparatively cheap.

THE ANALGESIC ACTION OF ELECTRIC LIGHT.

Dr. Th. V. Stein, of Moskan reports in the *Deutsche Medicinal Zeitung*, April 6, 1891, fourteen cases illustrating the analgesic action of electric light. The results obtained are claimed to have been remakable. The electric light was applied by an especially devised reflector, designed by the author. In cases where the pain was located in the head or neck, these parts were illuminated for only 10 or 15 seconds, but other parts of the body were subjected to an illumination lasting five minutes or over, or until the patient complained of the intense heat. In a stubborn case of intercostal neuralgia in a woman one treatment resulted in a complete and lasting cure. The same results were observed in a case of lumbago, one of severe cough, one of rheumatism, etc.

THE TREATMENT OF PNEUMONIA.

Dr. W. Soltan Fenwick gives in the *Lancet* for January 31 and February 7, 1891, an analysis of a thousand cases of acute primary lobar pneumonia which were treated at the London Hospital between the years 1880 and 1890. Those cases in which the temperature ranged above 103° are for convenience classified as "sthenic," those in which the temperature remained below 103° are considered as "asthenic" in character. The treatment of the sthenic cases was of three kinds: 1. Expectant, consisting of the application of hot poultices to the chest and the internal use of expectorant and tonic remedies. Of the 493 cases in this class, 116 were fatal, or 23 per cent. 2. With quinine, consisting entirely of the use of quinine in large doses, 12 to 40 grains a day. Of 52 cases, 11 died, or 21 per cent. 3. Antipyretic. These cases were combated upon general antipyretic principles, similar to those employed in the treatment of other acute specific fevers. Only 10 cases were treated with antipyrine and phenacetin, hence the inquiry is confined to the results which attended the systematic efforts to control the symptom of fever by direct abstraction of heat. The various measures resorted to were the use of—

1. The ice bag. Of 26 patients so treated, 4 died, or 15 per cent.
2. The cold pack. Of 26 patients, 4 died, or 15 per cent.
3. Cold sponging. Of 65 patients, 8 died, or 12 per cent.
4. The ice-cradle. Of 43 patients, 3 died, or 7 per cent.

There were 285 cases of asthenic pneumonia. Of these, 240 were treated in the ordinary way with poultices, stimulants, and tonics; the deaths were 76, or 32 per cent. In 45 cases the treatment was supplemented by large doses of quinine; the mortality was 20 per cent.

In summing up the foregoing results, Dr. Fenwick observes that the termination in the fatal cases was almost invariably directly due to failure of the heart. There are two factors which are capable of producing the condition of cardiac insufficiency—an increased resistance to the propulsive action of the heart, and a progressive deterioration of its muscular substance. In acute pneumonia both these factors are present; the former in the increase of tension in the pulmonary circuit consequent on the consolidation of a portion of the lung, and the latter as a direct result of high temperature. The action of these two forces is to compel the heart to beat more forcibly and more quickly, while at the same time it is steadily deprived of the power to do either. Treatment should therefore be directed to one special object—viz., to economize cardiac force by minimizing the injurious influences of fever. He believes that this is the best accomplished in the sthenic cases by the use of cold sponging or the ice-cradle.

In pneumonia of the asthenic type cold should not be employed, but the treatment should be stimulating.

Dr. Fenwick adds, in conclusion, that the quantity of albumin in the urine during the first three days is of considerable prognostic value; of patients with a quarter albumin, 32 per cent. died; of those with a third, 52 per cent. died; and of those with a half, 82 per cent. died.—*N. Y. Med. Jour.*

METHYL-BLUE AS AN ANÆSTHETIC.

Pietrowski has verified the statement of Ehrlich that methyl-blue is possessed of anæsthetic power to a remarkable extent. He has administered it both by way of hypodermic injections and by the mouth, to ten cases, including patients suffering from acute rheumatism and neuralgia of the intercostal, supra-orbital and sciatic nerves, as well as from lumbago. In all of these cases the urine became first green and then blue. After these injections there was some redness and tumefaction and perhaps some pain. In every case the pain was diminished.—*Revue Internationale de Bibliographie.*

STRYCHNINE IN THE TREATMENT OF CHRONIC ALCOHOLISM.

Dr. V. N. Ergolski reports in *Vratch* for March 7, 1891, ten cases of chronic alcoholism treated with more or less marked success by means of strychnine. The following are two of the cases reported in this article: The first was that of a gardener, thirty-four years of age, who often drank to excess, but did not regard himself as intemperate, claiming that he drank only when he had plenty of money and was in good company. At the solicitation of his mother, however, he submitted himself to treatment. On the first day he received a hypodermic injection of $\frac{1}{60}$ grain of nitrate of strychnine, $\frac{1}{40}$ grain on the next day, and $\frac{1}{20}$ on the third and following days. During the entire course of treatment, and for two weeks afterward, the patient did not drink anything, giving as his excuse that he had no money; but his mother said that he had never gone for so long a time without liquor in twelve years. Finally he thought he would try once more how vodka tasted. But after taking two glasses he became very drunk,

had a violent headache, vomited profusely, and had to be taken home and put to bed. He tried the experiment again in a week or two, with the same result. He insisted, however, on resuming his old habits, saying that he did not want to lose his taste for drink, and began taking vodka, a few drops at a time, gradually increasing the dose until he could take his usual allowance without trouble. The second case was that of a railroad worker, who had been for ten years strongly addicted to brandy, so that every day he would take from a half to one bottle or more, feeling, unless he took this allowance, a great restlessness and a sense of drawing in the region of the stomach. He was anxious to overcome his habit, but had not the will-power to do so. The first day after coming under treatment he received a hypodermic injection of $\frac{1}{40}$ grain of nitrate of strychnine. Upon presenting himself the next day, he reported that he had had none of the restlessness or dragging at the stomach, although he had not touched a drop of vodka. Dr. Ergolski administered $\frac{1}{20}$ grain subcutaneously this and the seven following days, after which he dismissed the patient, giving him 1 grain of the remedy divided into sixty pills, of which he was instructed to take one a day every alternate week. On the fifth day of treatment the man attended the name-day festival of a relative, where he was pressed to join the others in drinking the health of the host. He felt, however, a loathing for liquor, and would not touch it although the company made sport of him for refusing. The patient reported to Dr. Ergolski at the end of fifteen months, at which time he was perfectly cured. The eight other cases were similar to these, in all of which there was some good effects noted—in some a permanent cure, though in a few there was a relapse from one cause or another. The author regards the remedy in the nature of a specific for chronic alcoholism, and declares, as his belief, that it is possible to cure even the most obstinate cases by means of it, although in cases of relapse it may be necessary to repeat the course of treatment once or twice.—*Med. Rec.*

MEDICINE.

A CARCINOMA DISAPPEARS WITH THE DEVELOPMENT OF PHTHISIS,

As yet we know little of the analogy of various diseases, except as the history of some interesting case affords us some evidence and furnishes us with material for speculation.

Dr. Sigg, of Andelfingen, Switzerland, has recently reported the following interesting case, which is quoted in the *Wiener Medicinishe Presse*, May, 10, 1891. The patient was a woman 33 years old, who had a painful swelling of the left breast. The growth was hard, nodulated, partly adherent to the skin, and painful on pressure; the axillary glands in the left side were swollen and hard. In August of 1883, the growth was removed, and axilla cleaned out. In November of the same year a new growth appeared, below the cicatrix of the old growth, which rapidly increased in size, necessitating the removal of the remaining portions of the mammary gland. This was done February 28, 1884. On August 31, 1884, a third operation was rendered necessary, owing to the appearance of new growths. In January 1885, several new nodules made their appearance, and in April of the same year, had increased so rapidly, that the left side, from the sternum to the scapula, and into the axilla, was infiltrated, and covered with a flat growth, which rendered every movement of the shoulder, or elbow, impossible. Over the region of the left breast there were also several nodules, some as large as a man's fist. At this time the patient developed a cough, and gradually the typical picture of pulmonary phthisis presented itself. Bacilli were found in the sputum. With the appearance of the cachectic stage, the carcinomatous infiltration began quickly to disappear, and within a few days before the patient's death, no sign of the carinoma remained, except a small growth the size of a nut. A microscopical examination proved this to be an epithelical-carcinoma.

INFECTIOUS EYE-LOTIONS.

Dr. Franke, at a recent meeting of the Medical Society of Hamburg, called attention to the fact, that the instillation of solutions of atropin, eserin, and cocaine into the eye, frequently gives rise to acute conjunctivitis. The reason of this is, he claims, that these solutions are not antiseptic, and generally contain mould or fungi. Franke has found that if these remedies are added in the desired proportion to a 1 : 10,000 solution of bichloride of mercury, they will be kept antiseptic for an indefinite period, and not give rise to any irritative symptoms. In practice the addition of 2 drops of a 1 per cent. solution of bichloride of mercury to 10 grammes of any ordinary eye-lotion, will have the desired effect.—*Deutsche Med.-Zeitung*, May 4, 1891.

SOME NOTES ON THE PRESENT EPIDEMIC OF INFLUENZA.

Dr. Allen Greenwood states that the following observations are taken from his notes of a number of cases, and from his own unpleasant acquaintance with "Grip" in Waltham.

The attack usually begins with a feeling of depression, followed by dull pains, often becoming severe in the limbs and back, and often with chilly sensations. In almost every case these symptoms have been followed in twenty-four hours by a severe headache and a feeling of soreness in the throat, with painful deglutition. The inflammatory process soon extends to the larynx, and the patient becomes hoarse or loses the voice entirely; and it is here that the most painful part of the attack (to myself and several others) has been, for the pain about the region of the larynx has been intense, resembling the pain of a bad toothache or earache.

In about twenty-four hours after the beginning of the throat symptoms, the patient begins to cough, and soon there comes a feeling of tightness and soreness about the chest, the feeling of tightness often amounting to a suffocative sensation that is very distressing. The cough is accompanied by a varying amount of expectoration of a white or yellowish-white frothy material, which is occasionally streaked with blood. The expectoration becomes much less on the second or third day after the cough begins, and the dry cough remaining may last a week or more.

There is often more or less coryza, and there was in most of the cases a symptom I had never seen before, namely, a severe, dull pain over the frontal sinuses, probably due to a congestion of the membrane lining the sinuses. In my own case this pain lasted several days, and was accompanied by a marked swelling and tenderness of the integument over the sinuses.

The evening temperature when first taken, usually after the throat symptoms were well established, varied between 100° and 103° F. It remained about the same for twenty-four or forty-eight hours, with morning remissions of one or two degrees, and then fell by lysis reaching normal on the fifth or sixth day. Two of the cases were followed by acute otitis media, requiring paracentesis and the usual after-treatment for such cases.

The attack usually leaves the patient very weak, and it is often several weeks before full health is regained.

Physical examination of the chest did not show much beyond the few usual signs of a acute bronchitis of the larger tubes. In examining the throat I was struck by the absence of any follicular deposits, the appearances being invariably those of acute inflammation of the tonsils and pharynx, the surface of the whole region posterior to the anterior pillars of the fauces looking like raw beef.

In speaking of treatment, I shall only mention those things which in my few cases have given the most relief.

In no case has treatment been begun on the first day; but for the severe headache of the second day antipyrine, in fifteen-grain doses, has served me well, and given much relief to patients.

For the sore throat and painful laryngitis, hot, moist applications are indicated, either in form of poultices or cloths rung out of hot water; and the relief thus afforded, as I can testify, is very grateful.

For the feeling of soreness and tightness in the chest, nothing gave so much relief as a clear mustard paste to the front of the chest, left on fifteen or twenty minutes till the skin was well reddened.

At night the patient should take ten grains of Dover's powder, which will probably ensure a good night's rest; and this may be repeated the following night.

As the expectoration ceases, the cough becomes useless and distressing to the patient, and to relieve this one of the anodyne cough mixtures may be given. I have had very good success with a combination of morphine and hydrocyanic acid, as in the following:

℞

Morph. sulph.	gr. ii.
Ac. hydrocyan. dil.	ʒ i.
Syr. tolu	ʒ ii.
Syr. simp. ad	ʒ iv. M.

Sig. Teaspoonful every three hours, for cough.

This will usually stop or relieve the cough so that it need not be taken more than two or three times a day after the first few doses. One patient did not follow directions, but continued the medicine after the cough had stopped until such marked physiological effects of the hydrocyanic acid appeared as to frighten her.

For the painful congestion in the frontal sinuses, clothes rung out in hot water and laid on the forehead gave relief, as did also antipyrine used in fifteen-grain doses.

From other physicians here I learned that the type of the disease as given above is similar to that observed by them.—*Boston Med. and Surg. Jour.*

In Tokiyo over 12,000 bodies were incinerated last year at a cost of $19,000.

SURGERY.

SOME PRACTICAL POINTS IN ABDOMINAL SURGERY.

Dr. Jno. H. McIntyre, in a paper read before the State Medical Association of Missouri, states that in his opinion, among anæsthetics, the safest and best is bichloride of methylene used in Junker's Inhaler. He has used it in laparotomy work for the past ten years without a single untoward sympton, and with the greatest satisfaction, and upon many occasions has put it to as severe a test as it is possible to put an anæsthetic.

By its use, anæsthesia can not only be promptly induced, but safely maintained for any desirable length of time, and it is rarely followed by nausea and vomiting.

By the use of the inhaler of Junker, overdosing is next to impossible, in reality the patient takes inspired air, charged with the vapor of bichloride of methylene, and it is surprising what a small quantity is required in doing a prolonged operation.

Short incisions constitute another point of excellence, and should never be extended beyond the point of necessity in removing a growth of given size without bruising the tissues. In removing the ovaries or fallopian tubes, or both, it is rarely that the ventral incision need be over two inches in extent.

In dealing with adhesions, perseverance by well directed effort will always succeed; remembering, however, that violence is always harmful, and the necessary force should be that of gentle momentum.

Intestinal adhesions, should be separated as far from the gut as possile, for by so doing the danger of hæmorrhage is much lessened; they should be carefully examined afterward, as the placing of a Lembert suture in the proper place at the opportune moment, will prevent the mortification of a future fecal fistula.

In the management of the pedicle he always uses Japanese cable silk, transfixing the tying the ordinary surgical knot, when dealing with large tumors; for removal of the appendages, he is partial to the Staffordshire Knot of Tait.

Drainage.—"When in doubt" he always drains, and prefers the Keith tube to all others, and he is a thorough believer in flushing the abdomen with a large quantity of hot distilled water; it is marvelous sometimes to see how many blood clots can thus be washed out, even after careful sponging, besides it is one of the best methods of relieving shock.

Closure of ventral wound can best be done with silk worm gut; it is the ideal suture, as it is round, smooth and very strong, and can be rendered perfectly aseptic. As it is rather stiff, it should be steeped for a few hours before using, in a solution of some kind, so that it can be tied tightly. It should be threaded at each end upon straight or slightly curved veterinary needles. The needle being held in the grasp of the Spencer-Wells needle holder, should be passed from within outward, always including the peritoneum. Sutures should be placed five or six to the inch. The frequent cause of ventral hernia following abdominal section, is an insufficient number of sutures.

After Management.—For the first twenty-four hours, nothing should be taken into the stomach, except a little hot water, bits of ice chewed or swallowed do not relieve thirst. The second day a little barley water may be allowed, and on the third day she can be promoted to a chicken wing, when afterwards, if everything goes well, almost any light diet may be allowed.

When pain is present, he uses but little morphia, on account of its tendency to arrest secretions; and thereby prevent the elimination of morbid material, but in its stead, for more than a year past, has used antikamnia, with happy effect. It soothes and tranquilizes, and lessens the tendency to rise of temperature.

Stitch-hole sinuses can best be obviated by early removal of the sutures. It is rarely that he allows sutures to remain in the ventral wound longer than the eighth day, and he often removes them as early as the sixth.

He who essays to do abdominal and pelvic operations, should by previous observation and training, be so fitted for his work, that when he comes into "action" he will be "ready for anything, and surprised at nothing."

The best place in which to obtain the highest grade of success, he thinks, is not in large general hospitals, neither is it in "the cottage by the wayside," but in a small especially prepared establishment, under the absolute control of experienced management.

EXCISION OF PORTIONS OF THE LUNGS OF DOGS.

In view of the universal interest excited in relation to tuberculosis in all its now recognized manifestations by the announcement that Koch's tuberculin acted upon tuberculous tissue, causing its death *in situ*, but not rendering the necrotic tissue innocuous, it occurred to the members of the Stillé

Medical Society to undertake the following research, which was performed by Bolgiano, Patek and Sailer in the Physiological Laboratory of the University of Pennsylvania:

A certain number of dogs were set aside for experimental research. The general plan of operation first adopted was to resect one or more ribs, draw out and ligate a lobe of the lung, cut off a portion and return the lung into the cavity. A catgut drain was then introduced into the thoracic cavity, and the pleura, intercostal muscles and skin was sutured. Of four animals experimented upon one died upon the table, two on the second day after the operation, and one not until the fifth day. Autopsies showed gangrene of the stump and empyema.

A different operative technique was then adopted. The sight of operation, previously selected in accordance with results obtained on the cadaver under forced respirations, was shaved and carefully disinfected. An incision about two inches long was made down to the intercostal muscles, and the tissues were dissected back a short distance on each side. A quick cut, about one and a half inches long, was then made through the intercostal muscles and pleura. Retractors were immediately inserted, and the ribs were drawn apart by an assistant, while the operator thrust in a pair of hæmostatic forceps in the direction previously determined, seized the lobe of the lung, drew it out and transfixed it with a sharp probe. As soon as this was accomplished the retractors were withdrawn, allowing the ribs to close upon the lung tissue, the probe preventing retraction during inspiration. The external portion of the lung was now removed by a V-incision. A needle, threaded with antiseptic gut, was passed through the intercostal muscle, pleura and tissue of the lung beneath the incision, and out through the pleura and intercostal muscle of the other side. These sutures were repeated about one-eighth of an inch apart until the wound in the thorax was closed, the wound in the lung being closed at the same time. A catgut drain was now laid over the wound, and the edges of the skin were brought together. Owing to the difficulty experienced in controlling the dogs, it was found necessary to dress the wound with a solution of collodion and iodoform in ether upon a matrix of cotton.

By this method three dogs were operated upon with most satisfactory results. During the operation shock was not experienced, and but little hæmorrhage occurred. In each case the dogs reacted well. Respirations were at first somewhat rapid, and there was an insignificant rise of temperature during the twenty-four hours following the operation. The appetite was good throughout.

One dog was killed and examined on the tenth day after the operation, the trachea being ligated previous to the opening of the thorax to prevent collapse of the lungs. The lung was found to have healed perfectly to the thoracic wall without the occurrence of circumjacent pleurisy. The pneumothorax had been wholly absorbed and the function of the lung restored.

Three weeks after operation the second dog was killed and the thorax opened under forced respiration. The wound in the lung had healed completely, leaving a small white cicatrix, and the lung itself had become detached from the thoracic wall. The pneumothorax had been wholly absorbed and the function of the lung completely restored. Indeed, the result may be looked upon as a perfect cure. In both instances about 0.5 gram of lung tissue was removed from the lower lobe of the right lung.

From the third dog the whole of the upper lobe of the left lung was removed—a piece about three inches long, and weighing 5 grams. It was necessary in this case to ligate the bronchial artery, but the operation was performed without further complications. The dog recovered promptly and is now living in excellent condition.

We think that we may fairly consider these results as indicating a thoroughly satisfactory method of excising portions of the lung from dogs. Whether it is equally applicable to human beings, experience alone can demonstrate. Reasoning *a priori* it would seem that this technique might be adopted in surgery, for none of the steps depend upon any anatomical peculiarity of the subject. What result it promises it is, of course, impossible to say, but the beneficial results of operative interference in tubercular peritonitis strongly indicate that much good may come from surgical interference even when such important viscera as the lungs are involved.—*Univ. Med. Mag.*

GYNÆCOLOGY.

SALICYLATE OF SODA AS AN EMMENAGOGUE.

Dr. C. Mettenheimer speaks highly of salicylate of soda as an emmenagogue. He bases his opinion on a series of cases, one of

which is reported in the *Allgemeine Med. Central-Zeitung*, May 6, 1891.

The patient was a married woman, 35 years of age, and of vigorous constitution. During the prevalency of the grippe she caught cold, and complained of chills, pains in the limbs, headache, loss of appetite, pain in the eye-balls and great lassitude. The symptoms were not severe, and the febrile symptoms were very slight. The following prescription was given:

℞ Natron. salicyl..... 6.0 grammes.
Aq. dest ....75.0 grammes.
Syr. aurant. cort.....25.0 grammes.

M. et Sig. One tablespoonful every hour until perspiration occurs.

After the patient had taken two doses she began to perspire, and also her monthly period appeared, which had been delayed for over a week. Otherwise she had always been most regular. The menses followed their normal course, and the patient made a speedy recovery.

ICHTHIOL IN DISEASES OF THE GENITALIA OF FEMALES.

Dr. Richard Bloch, in the *Journal de Med. de Paris*, May 10, 1891, speaks most highly of the value of ichthiol in the treatment of various inflammatory diseases of the female genitalia. He considers it far superior to nitrate of silver, creolin or carbolic acid. Dr. Bloch bases his conclusions on a long list of cases in which the drug has proved itself of signal service. It seems to have a specific action in diseases of genital mucous membranes, but produces no local or general reaction, and is not in the least toxic. Intra-uterine injections of a 10 per cent. solution of ichthiol in glycerine are of great value and produce no untoward symptoms.

The application of pure ichthiol to the vaginal mucous membrane produces slight erosions, and therefore occasion some pain.

The drug diminishes both vaginal and uterine discharges. In acute inflammations, whether blennorrhagic or not, it is most efficacious. In metritis of the cervix it is most valuable, and in cervical erosions the application of the pure drug will cause prompt healing.

TACHYCARDIA AT THE MENOPAUSE.

It is not many weeks ago that the subject of rapid pulse received attention in our columns, but of the numerous authors cited, none had studied the pnenomenon in connection with the climacteric. This study has occupied the attention of Professor Kisch, of the Prague faculty, a resident of Marienbad, and he has made it the basis of an able article in a recent number of the *Prager Medicinische Wochenschrift.* Marienbad is a well-known resort for women approaching the change of life, and the author has had ample opportunities for studying the varied and complex nervous and circulatory disturbances of that period. As his conception of tachycardia differs somewhat from that of other reliable observers, it may be well to give his definition of it. He defines it as a purely nervous affection, not dependent upon any organic disease of the heart and blood-vessels, manifesting itself in a change of the motor fuction of the heart, and making itself evident in a decided, at times extraordinary, increase of the frequency of the heart's contractions. Although the various morbid phenomena attendant upon the change of life have received apple attention, this functional affection of the heart has gone almost unnoticed. Stokes, however, in his well-known work on *Diseases of the Heart*, mentions a form of palpitation at the menopause that is at times attended with paroxysmal attacks of great rapidity of the pulse.

Kisch's clinical picture of the affection is as follows: At the time of the menopause, occasionally after the cessation of the menses, but most frequently between the ages of forty and fifty years, when the menstrual flow is beginning to show signs of change, paroxysmal attacks of palpitation may occur in women whose heart's action has previously been quite normal. These attacks sometimes come on without any provocation, and at other times they are evoked by slight causes, such as would have no effect in a normal state of health. The attacks may come on while the patient is in any posture—walking, sitting, or lying down, and even during sleep. The subjective symptoms accompanying the attacks are a feeling of oppression and of anxiety, throbbing in the carotids and in the abdominal aorta, severe headache, and fugitive sensations of heat and of a rush of blood to the head. Occasionally there are noises in the ears, flashes of light before the eyes, and dizziness, and, in rare cases, syncope may occur. Objectively, it is found that the pulse numbers from 120 to 150, and may even reach 200. In most cases it is full, powerful, and regular. The sphygmographic tracings show a high pulse wave, a rapid and abrupt rise of the ascending line, and an equally rapid and abrupt fall of the descending line. Redness of the face, neck, and chest is the contrary, there was a tendency to plethora, and the patient had a dread of a stroke of apoplexy. The duration of the

affection may vary from a few weeks to two years and even longer.

In the tachycardia of the menopause the author thinks the ætiological facor is hyperplasia of the ovarian stroma. This increase of connective tissue in certain predisposed individuals, acts in some way, unknown as yet, upon the terminal nerves of the ovarian tissue and, through them, in a reflex manner upon the sympathetic nerve—the accelerator of the heart. This assumption receives support from the fact that tachycardia is frequently seen after the operation for the removal of the ovaries, which is followed by a shrinking process of the internal genital organs. In the way of treatment, the author has obtained the best results from a systematic course of mild purgatives, suitable dietetic and hygienic regimen, such as mountain air, a bland diet, and active bodily exercise, and wet applications to the lower part of the abdomen. A course of some weeks at Marienbad is usually followed by improvement. Small doses of the bromides generally afford relief from the unpleasant sensations attending the attacks.—*N. Y. Med. Jour.*

OBSTETRICS.

UNCONSCIOUS PARTURITION IN A PRIMIPARA.

A case of high obstetric and medico-legal interest is to be found in the *Archives de Tocologie* for November. Physiologically painless parturition is rare. Tarnier has related some cases, including one instance where a Canadian woman occasionally dropped a baby on the ground, at term, without noticing it. In Howard's case labor took two hours; the patient was reading a book till a quarter of an hour before the child was delivered, which event occurred after some straining, not sufficient to make her cry out. In Dr. Brunon's case, newly reported, a married woman, aged twenty-two, had a troublesome cough one day shortly before term. The coughing was accompanied with lumbar pains, which increased. At eleven o'clock in the evening the patient tried to pass a motion. She sat over one hour in the closet, believing that her pains signified painful defecation. Then she went to bed. At half-past one o'clock she woke up feeling a desire to pass a motion, with lumbar pains such as she had felt before when constipated. As she rose to go to stool a smart lumbar pain occurred, and she felt something between her thighs. On handling it she found, much to her surprise, that it was the head of her first-born. She declared to Dr. Brunon that the pains were entirely lumbar, she had no colicky sensations, and none of the expulsive pains usually so severe, especially in primiparæ. The desire to defecate was strong, and she stated that the child might have been born into the pan of the closet without her recognizing the truth of her condition till the moment of its delivery. The patient was an intelligent well-educated woman, free from any neurosis. This case proves that in the case of an inexperienced person an infant might be expelled into the water in the pan of a closet without any intention of infanticide on the part of the mother.—*Epitome.*

THE NECESSITY FOR IMMEDIATE SURGICAL INTERVENTION IN LACERATIONS OF THE PERINÆUM.

The misfortune which has just happened to an unfortunate practitioner, who was mulcted damages to the amount of nine hundred dollars and costs by the Superior Court for neglecting a lacerated perinæum, should be a lesson to every accoucheur in this country. It was shown that the laceration was complete, extending into the rectum, and had been followed by procidentia of the uterus and other distressing accidents.

The duty of attending to all extensive lacerations of the perinæum at the time when the lesions are fresh is insisted upon by the best obstetrical writers, and it is certainly the practice of the most successful obstetricians in this country to immediately put in three or more deep stitches, thus approximating and keeping in apposition the lacerated parts till union takes place. It matters little what material is used for the sutures; some use chromacized catgut, and make a deep continuous suture, and certainly catgut has in many instances proved to be sufficiently enduring; others prefer silk, others silver wire. Every physician has, or ought to have, in his pocket-surgical-case, ligatures and curved needles, and if a sufficiency of interrupted sutures are inserted immediately after confinement, the old-fashioned quilt suture may well be dispensed with. It will not always be necessary to give the patient ether in order to insert the stitches, though some nervous and susceptible subjects may require it. It is true that after a long and difficult confinement case, the medical attendant is generally tired out and shrinks from another operation, especially where anæsthesia is required, but he must muster strength and nerve for the occasion if he

would escape liability to a suit for malpractice; and if he inserts a few stitches he will save himself from the imputation of ignorance or carelessness. Modern juries have not the name of being very tender to the feelings, reputations or pockets of physicians, and it goes without saying that the most vigilant and attentive will be the least likely to be "caught napping."

There are one or two errors that should be cleared away, lest they should be subterfuges for the careless. The one is that tying the knees of the patient together will answer the same end as sutures. "Only a very credulous person," says Lusk, "really believes that he has witnessed union by first intention in extensive ruptures as the result of tying the knees together, and enjoining rest upon the side. The action of the transversi-perinei muscles tends to draw the torn surfaces apart. Moreover, the necessity of separating the knees in passing urine, and to enable the nurse to clean the genitalia, makes it impossible to keep them in contact for any lengthened period."

The other mistaken notion is that primary perineorrhaphy rarely succeeds, "that the perinæum is not merely torn but is contused and mangled, and that the previously œdematous and infiltrated tissues are predisposed to gangrene, and consequently are in the worst possible condition for immediate union" (Charpentier). Moreover, it is said that the lochial discharge will always be an obstacle to the union by first intention.

According to the experience of very many who have tried the immediate operation, and who have seldom or never failed to obtain good union, if due pains toward cleanliness and antisepsis are taken, no such unfavorable result as Charpentier points out need ever be feared. Certainly, Charpentier's American editor warmly favors the immediate repair of any laceration beyond the first degree, for the reason that thus a possible entrance sight for septic matter is prevented, and also because the operation is a simple affair after delivery, and more extensive and complicated, the longer we wait. He recommends that in case of laceration to the second degree only one deep silk or wire suture should be used; if the rent be deeper, three to five will be needed. In any event, the patient should be placed on her side, a wad of absorbent cotton inserted into the vagina to catch the discharges, the wound carefully washed and trimmed of jagged shreds, and then, guided by the finger in the rectum, the suture is passed deeply around, at one-half inch from the margins. The line of suture should be dusted with iodoform, and a narrow strip of cotton laid along the perinæum and the posterior vaginal wall. The after-treatment will consist in dusting with iodoform twice daily, and replacing the strip of cotton by a fresh piece till the sixth or seventh day, when the sutures may be removed.—*Bost. Med. Surg. Jour.*

PÆDIATRICS.

TREATMENT OF DIPHTHERIA BY MERCURIAL INUNCTIONS.

Smakowsky, in the *Allgemeine Med. Central-Zeitung*, May 13, 1891, reports three cases of diphtheria, which recovered after inunctions of mercurial ointment. Every hour 4 grammes of mercurial ointment were rubbed into the skin of different parts of the body, as in the treatment of syphilis. In this way the patient got, in all, about 30 grammes daily. The only other treatment that was used was gargling with a solution of chlorate of potash. The treatment lasts for one day only. If there is any relapse it may be repeated. Unfortunately the treatment is of little value in the treatment of infants, since they cannot gargle. The patients treated were from seven to eight years of age.

QUININE IN WHOOPING-COUGH.

Professor Emil Ungar, advocates the free use of quinine in whooping-cough (*Deutsche medicinische Wochenschrift*, No. 18, 1891), having used it with much success during several epidemics in the last six years. He attributed the great differences of opinion as to its value which have prevailed amongst previous observers to the difference in the dose employed. Large doses are necessary, and, suiting the exact quantity to the age of the patient, he advises the use of from 16 to 22 grains per diem, in divided doses. Even to children below three months of age he would administer $\frac{3}{4}$ of a grain at each dose. These large quantities are only given for a few days, and as improvement begins the dose is diminished, and is given twice or only once a day instead of three times. This diminution should be effected slowly. Dr. Engar believes that children will bear relatively larger doses than adults, and has had no experience of the deafness or disturbed digestion which the drug is said to have produced in the hands of other observers. In his cases the vomiting, after the paroxysm, was rapidly stopped, and appetite

and digestive power seemed to be improved. The recorded cases of aural disturbance are for the most part in adult persons, and not in children. No untoward results of the treatment occurred in his practice, the only symptom presumably attributable to the equinine being the occurrence of very rapid cardiac action in one case. The main difficulty in the way of the administration of quinine to very young children is its bitter taste. Perseverance in many cases was rewarded by the children actually becoming fond of it, although almost all rebelled at first. The struggle induced during the swallowing of the medicine is apt to produce a fit of coughing, followed by retching and vomiting. In order to avoid this occurrence it is advisable to give the quinine directly after a paroxyism has taken place. To older children the quinine may be given in capsules. Administration *per rectum* is not satisfactory. By subcutaneous injection good results may be obtained, a neutral hydrochlorate being used, which is fairly oluble in water. The curative effects of quinine, however administered, are not apparent immediately, except in a few instances. As a rule, from three to six days elapse before the severity of the attack begins to diminish and the vomiting to cease. The disease then appears to run a milder course, and at the end of a fortnight the attacks are slight and infrequent. The tendency to complications, broncho-pneumonia, etc., is lessened, and improvement may be looked for in the large majority, though not in all cases.—*Brit. Med. Jour.*

THE SCARLET FEVER TONGUE.

The method followed by Dr. Newman was to sketch the tongue as soon as the diagnosis of scarlet fever was made, and after two or three days to compare its condition with the sketch already made. This was done in forty-eight cases, the chief symptoms of the disease being noted at the same time. The mucous membrane of the tongue passed through three stages: 1. Swelling and cloudiness of the epithelium; 2. desquamation; 3. regeneration of the lost epithelium. The first thing noted in the scarlet fever tongue is a swelling of the entire mucous membrane, giving rise to longitudinal folds and channels, easily distinguished from the folds noted in bulbar paralysis by the consistency of the tongue. The cloudiness of the epithelium gives rise to the changed color of the tongue; it appears grayish-white, white, or yellowish-white—that is, the tongue is coated. The back of the tongue is chiefly affected, the sides and tip being red. The desquamation does not take place as uniformly over the tongue as the other processes. It commences on the papillæ fungi-formes. These latter appear as submiliary or milary round, dusky-red dots, surrounded by a white area. Thus the tongue gets its strawberry appearance. In the third stage the sides of the tongue, and more particularly its tip, retain their red appearance and strawberry aspect longer than other parts of the tongue. The new epithelial layer may be so thick that the tongue appears coated anew. The swelling gradually goes away. The above is the usual course, but there may be departures from it. In two cases the dulling of the epithelium was absent, and the desquamation excessive, so that the longitudinal muscle bundles were seen. In another case, the epithelium was only detached in part, and a new layer developed quickly, so that the tongue appeared coated throughout. It resembled a dyspeptic tongue. The author says that the fungiform papillæ appeared round and erect; whereas in the dyspeptic tongue they are elongated, and slope toward the tip of the tongue. Generally speaking, the digestive troubles cause the tongue to be coated before the scarlet fever process has had time to affect it. If scarlet fever be combined with a septic condition, the latter determines the condition of the tongue. As the new infection appears early or late, so is the scarlet fever process interrupted. Generally speaking, the tongue, after losing its epithelium, developes a strawberry appearance, and then becomes dry. Bleeding cracks may be seen, which can lead to deep ulceration, or true diphtheritic membrane may appear. Out of the 48 cases the tongue was typical in 38. In 4 cases, one or two of the stages were only very slightly developed; and in 6, the typical scarlet fever tongue was altogether absent. Of these 6, there was severe gastric disturbance in 2; another case was in a chlorotic girl; in the fourth case there were symptoms of septicæmia, and death on the fourth day; and in the fifth and sixth cases the tongue was quite unaltered. Thus it would certainly appear that the scarlet fever tongue is a tolerably frequent occurrence in the disease, and that when absent, complication or previous illness has altered the tongue in other ways. The tongue recovers its normal state with the cessation of the fever. In the majority of cases the tongue had lost its epithelium, and had become strawberry in three to five days. There is no proportionate rela-

tion between the intensity of the scarlet fever poison as it affects the skin and tongue. Both processes are probable brought about in the same way, as their tolerably equal occurrence and their appearance much about the same time would suggest; and again, certain departures from the ordinary have shown a peculiar resemblance. Thus in one case with a puerpuric rash, the same was noted on the tongue; and in another, where syphilis was present as well, pustules were seen on the tongue as well as on the skin. Thus this condition of tongue, though not always present, is observed in many cases. It is, however, of less value than it might be, as it does not appear before the fourth day or so, and it may certainly be present in other illnesses.—*Deutsches Archiv fur Klinische Medicin.*

HYGIENE.

DR. KLEIN ON BACTERIA.

The first of a series of three lectures on Bacteria; their Nature and Functions, was delivered at the Royal Institution on Tuesday last by Dr. E. Klein, F.R.S. He said that perhaps in no branch of biological science had advances in the methods of research within the last twenty-five or thirty years been so enormous as in this subject. In 1828 Ehrenberg recognized the existence in water of minute mobile organisms which he considered to belong to the group of animalculæ known as infusoria, an assumption which was now known to be erroneous. In 1837 Schwann demonstrated the presence in atmospheric air and in dust of living microscopic beings, which he showed by direct experiment to be endowed with the power of producing in certain fluids those chemical changes termed alcoholic fermentation or putrefaction. Pasteur fully established the proposition that the different fermentations, such as alcoholic, butyric, acetous, mucous, and lactous fermentations, and also the decomposition of putrescible matter, were caused by definite and different species of such minute living beings—microbes,—and that without them such changes did not occur. This proposition implied that these changes were dependent on and ultimately bound up with the life and growth of these microbes, and if these were prevented from gaining access to such fermentative matters, they would remain unchanged or sterile. This was the principle which Sir Joseph Lister had applied in surgery, with the well-known brilliant results. The *role* of these microbes in atmospheric air had been minutely worked out and beautifully illustrated by Professor Tyndall, whose share in finally establishing that with these simple organisms, belonging almost to the world of the infinitely small, the same fundamental principle obtains as in other living organisms of plant and animal life, be they ever so large and complex—namely, that each organism had descended from an antecedent parent organism, and that no such thing as their origin from non-living matter occurred. Within comparatively recent times it had been shown that a variety of the most important and extensive processes of oxidation and reduction occur in nature, such as the oxidation and resolution of dead animal and vegetable matter, the breaking up of complex nitrogenous materials—such as albuminous substances, and their ultimate change into nitrites and nitrates, so essential to the life and growth of plants; that specific fermentation, so important in food stuffs and articles of diet, and many other processes are caused by, and intimately connected with, the growth and life of microbes. Though the importance of some species as useful agencies in nature is recognized, the importance of other species, as being the cause of disease affecting plants, animals, and man, is not less. The term micro-parasite is given to this latter group. Amongst the microbes there is one great group to be dealt with in particular, called "bacteria," because it possesses more or less the shape of a minute rod. Like the true or higher fungi, they are free from chlorophyll, and are composed of cells, a cellular membrane with living matter or protoplasm within, and they multiply by fission, for which reason they are called "fission fungi." Bacteria could then be defined as microscopic elementary organisms, composed of a cellulose investment of the protoplasmic contents, and which multiply by simple fission. They are classified into micrococci or cocci, bacilli and spiral vibriones, according to whether they are spherical, cylindrical, or curved and spiral. The lecturer exhibited a large number of microphotographs of bacteria, prepared by Mr. Andrew Pringle and Dr. Bousfield.

All these organisms, when they have found suitable nidus, multiply with enormous rapidity. It has, for example, been found from observation—all conditions of moisture, medium, and temperature being favorable—that some multiply in twenty minutes, others in thirty minutes, and others in forty minutes. Staphylococcus

aureus, which in its growth produces a peculiar golden-colored filament, grows with great rapidity when sown in a medium-like, faintly alkaline broth at a temperature of 37°C. Into a sterile broth tube a definite number of organisms are put—say, eight cocci per cubic centimeter. If placed in an incubator for twenty-four hours at 37°C. and then counted, it is found that 1 cc. contains 640,000—that is to say, one organism has multiplied eighty thousand-fold in the first twenty-four hours. It would not be expected that the same rate would obtain in the second twenty-four hours, because the material had been used up. After forty-eight hours' growth the counting yielded 248 millions per cubic centimeter—that is, only four hundredfold. In seventy-two hours it was found that there were 1184 millions per cubic centimeter—that is to say, during the last day each had multiplied only fivefold. As the material is used up the rate of multiplication decreases. Another instance of the rapidity of growth was given. A rabbit was inoculated subcutaneously with 20,000 bacilli of fowl cholera, and died in twenty-four hours. It was found that 15,150,000 microbes were contained in 1 cc. of the blood of the animal. The whole of the blood contained twelve hundred millions, showing that each bacillus in twenty-four hours had multiplied sixty thousand times. Those organisms which have their habitat in ordinary temperatures grow very rapidly. Professor Ferdinand Cohn was the first to study the rate of multiplication on the hay bacillus. He calculated that in two days the number of these would be so great that the whole Atlantic Ocean would be densely peopled by them if there was sufficient nutriment, which, fortunately, there is not, and therefore many of them had to go to the wall.

By the motility of bacteria is understood active locomotion. They spin round, they dart to and fro, and pass rapidly over the field of the microscope, and that is on account of their possessing one, two, three, or even a multitude of fine hairs. The organism of typhoid fever possesses several of these flapellæ. It has been shown that for retaining this motility a plentiful supply of oxygen is required. If, in a chamber, at one end oxygen is supplied, and at the other nitrogen or hydrogen gas, the organisms will all move towards the end where the oxygen is. If the oxygen is replaced by nitrogen or hydrogen the movement gradually ceases. If water is covered with a scum, it is most probably a motile bacillus which grows in the fluid, and which is driven to the surface, where it can derive the best supply of oxygen. In many cases the motility of the organisms is interfered with by their own chemical products.

Within certain of these organisms, but not in all, are formed peculiar corpuscles, which bear the same relation to the organisms as the seed does to the plant. This spore formation is almost entirely limited to the order of bacilli, and in this group there are very many species which do not possess this power. In a number of different species of bacilli, some of which are capable of forming spores and others not, those which have this power may look on very quietly, while those that do not will exhaust all the nutritive material present, growth and multiplication will then cease, and they will gradually die away. Those which form spores have a much better chance of bringing forth new generations than the others.

When organisms do not find suitable materials for their growth, certain changes are brought about called "involution changes." When the bacillus ceases to possess that high degree of vitality that the normal typical bacillus possesses, it gradually undergoes changes which lead to its death. Illustrations were given of what had been described as involution changes, but which were not so. For instance, tubercle bacilli grown under not very favorable conditions may be swollen, and others may appear branched. Some observers took these changes to indicate the death of the organism, but the lecturer was not quite sure that such were "involution changes."

In all these considerations, particularly in reference to the formation of spores, there were a number of facts of very considerable practical importance. The germination of those organisms which form spores takes place on the same principles as the germination of the spores in the higher fungi. The envelope is broken, the protoplasm contained within it shoots out in the shape of a rod, which when it is fully formed elongates, divides and multiplies as in the case of the parent. In this way one bacillus, by repeated multiplication, forms a new crop. When these have reached a certain phase of development they again form spores which go to start a new generation. These spores have a much greater power of resistance than is possessed by the non-spore-bearing organisms, and can withstand high temperature, dryness and the influence of light, so much so that it has become almost a recognized method of determining whether a par-

ticular species of bacilli forms spores by subjecting the suspected organism to a temperature of 95° C. or 100° C. If they survive this exposure, and if they survive drying, it may be taken as established that the growth is spore-forming.—*Lancet.*

MEDICAL CHEMISTRY.

THE ALKALINITY OF THE BLOOD UNDER NORMAL AND PATHOLOGICAL CONDITIONS.

E. Pieper (*Arch. f. Pathol. Anat.*, 116, 337; *Ber. Deut. Chem. Ges.*, 23, 666) found that the alkalinity of the blood varies within narrow limits. The blood of children is less alkaline, in reaction, than that of adults; of women, less alkaline than of men. The alkalinity of the blood is increased during *digestion, muscular activity* and *vomiting.* The spasms of strychnine poisoning cause a decrease.

The author states that in *leukemia, diabetes mellitus, arthritis deformans, chronic articular rheumatism, anemia, cancerous cachexia uremia,* and in fevers the alkalinity of the blood is, as a rule, decreased, while in chlorosis it is increased.

ESTIMATION OF NITRATES AND NITRITES IN WATER BY ELECTROLYSIS.

At the recent annual meeting of the Bristol (Eng.) Pharmaceutical Association, G. F. Schacht, presented a paper on this subject. After alluding to the importance of being able to determine the wholesomeness of potable water, he discussed as his special point in such determination a recent suggestion to employ a "couple" of aluminium and mercury for the evolution of the hydrogen in the well-known process for the estimation of nitrogen existing as nitrates and nitrites in the sample. Messrs. Ormandy and Cohen had published this suggestion, and their paper had appeared in the *Journal of the Chemical Society* for September of last year. He had taken some pains to assure himself of the accuracy of the method, and, with the modifications to which he would presently refer, it became so easy of execution that he recommended its adoption with confidence. Mr. Schacht then proceeded to show the process in detail, and to describe it thus: Measure 100 c. c. of the sample into a plain upright glass vessel of capacity equal to about 130 c. c.; take a strip of aluminium foil (about three inches of ordinary ribbon= 0.4 gram), clean both surfaces by rubbing with tow dipped in liquor sodæ, wash thoroughly and dip it into a solution of mercuric chloride (half a saturated solution and half water) for one minute. A deposit of mercury takes place upon the aluminium, and a "couple" is formed. Wash it well under the tap, put it at once into the 100 c. c. of the sample, and cover the glass vessel loosely. Let these react until the metals become a deposit and no more gas is evolved. Gently stir the mixture and allow the deposit to subside. Take 10 c. c. of the clear supernatant liquid, dilute with 90 c.c. of pure water, and add 1 c.c. of Nessler's solution. Note the color. Perform a comparison experiment in the usual way with standard solution of ammonium chloride 0.0001 gram of NH to each c.c. Then x being the number of c.c. of solution required $0.0001 \times x \times 10 \times 700$=grains per gallon of ammonia, and this figure multiplied by 0.828=grains per gallon of nitrogen. In experiments which aim for exact results, it is better to close the mouth of the vessel with an india rubber stopper through which passes a glass tube, bent so as to allow the gasses to pass through a small quantity of water, which should be mixed with the sample before the final stirring. The author submitted a table of results of experiments, which showed that great accuracy could be attained by this process.

NEWS AND MISCELLANY.

ANATOMY AT OXFORD UNIVERSITY.

A grant of $35,000 has been asked by the Convocation to procure permanent accommodation for the teaching of anatomy.

DR. LASSAR.

The French Government has conferred the Order of the Legion of Honor on Dr. O. Lassar, the General Secretary of the Tenth International Medical Congress, held in Berlin in 1890.

THE CHICAGO MEDICAL RECORD.

This is the title of a new medical monthly edited by Dr. Archibald Church. It is well printed and contains a number of valuable original articles, together with society reports, etc.

THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF TEXAS.

The Medical Department of the University of Texas, will open its doors in the Autumn

of this year. Dr. Thos. D. Wooton, of Austin, is the Regent. A large Hospital will be adjacent to the school, and every effort is promised to make the school one of very high standard.

RESIGNATION OF SURGEON-GENERAL JOHN B. HAMILTON.

Dr. John B. Hamilton, Surgeon-General of the Marine Hospital Service, has resigned to accept the chair of Surgery and Surgical Pathology, in the Rush Medical College, of Chicago. Dr. Walter Wyman, who has been his chief assistant, has been promoted to the vacant position.

THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

At a recent meeting of the Directors of the New York Post-Graduate Medical School and Hospital, H. J. Boldt, M. D., was made Professor of Diseases of Women; William James Morton, M. D., Professor of Electrotherapeutics, and Aug. Caillé, M. D., Professor of Diseases of Children.

A NEW CREMATORY.

The incineration of the dead becomes more and more popular. Crematories are rapidly increasing in number in all civilized countries. One of the most important structures of this kind will be at Heidelburg, a site having been given by the municipality for the purpose. The cost of erection is estimated to be over $10,000.

THE UNIVERSITY OF PENNSYLVANIA.

The Trustees of the University of Pennsylvania have elected—Dr. George A. Piersol, Professor of Anatomy; Dr. Harrison Allen, Professor of Comparative Anatomy; Dr. John B. Deaver, Assistant Professor of Applied Anatomy; Dr. Edward Martin, Clinical Professor of Genito-urinary Surgery; and Dr. Holmes, Demonstrator of Anatomy.

THE LEHIGH VALLEY MEDICAL ASSOCIATION.

The eleventh annual meeting of the Lehigh Valley Medical Association will be held at the Mansion House, Mauch Chunk, Pa., on Thursday, June 25, 1891.

During the morning business will be transacted and papers read. At 3 P. M. the Society will take in an excursion on the "Switch Back."

UNIVERSITY OF BUDA-PESTH.

A festal commemoration of the 111th anniversary of the University of Buda-Pesth was held on May 12th.

Prof. Koranyi on the 14th inst., celebrated the twenty-fifth anniversary of his appointment as Professor, and received over 200 congratulatory telegrams.

The Medical Society has decided to build itself a house which will probably cost about $20,000.

FOOT-BALL CASUALTIES.

The last foot-ball season in England has been noted for the casualties recorded. Among the injuries noted in the Lancet, which ended fatally are, asphyxia, caused by paralysis of the muscles of respiration, acute peritonitis, injury to the brain, rupture of the intestine, rupture of the right kidney and abdominal injuries. Is it not time that this game should be so modified as to relieve it of the unnecessary dangers now attending it?

WHO OWNS THE PRESCRIPTION?

The *British Medical Journal* says that the question of the ownership of prescriptions has been settled by law in New York, Massachusetts, and a few other States. In all the cases it has been decided that the druggist is the owner of the prescription. The following is the text of a judicial pronouncement lately delivered on the subject: "The question before the Court appears to be simple indeed. A patient applies to a physician and receives from him certain advice for which he tenders a fee. The physician hands a piece of paper to the patient, purporting to be a written order for certain goods, called drugs, which order is filled by a merchant or apothecary. The payment of the fee and the delivery of the goods or drugs terminates the verbal contract, and the druggist keeps the prescription as an evidence that the contract has been fulfilled so far as he is concerned. The druggist can, if he so please, on his own responsibility renew the drugs, for he is but a merchant, and has a perfect right to sell drugs to anyone and in any shape. He need not keep the prescription, nor is he bound to give a copy; but should error occur, he has no protection in case of

suit." It is said that some time ago a decision in the same sense was given by the judge of a court in Berlin.

The *Journal* adds in comment on the above: "The opinion here quoted does not seem to be sound; the patient receives the prescription in return for the fee which he gives to the physician, but he is under no obligation to give up the prescription to the druggist. He is bound to show it to him, or else he cannot get the drugs he wants, but the document belongs to the patient, who could, if he choose, enforce its return by action. A publisher might as well claim to keep an author's manuscript as evidence that he had correctly printed it, as a druggist to keep the prescription as evidence that he had fulfilled his contract to supply the drugs ordered of him. Such a claim on the part of a tradesman against his customer is not recognized as valid by English law, whatever may be laid down by the courts of other countries."

In a paper recently read by Mr. Joseph England, before the Philadelphia College of Pharmacy, this question of ownership was discussed, the writer taking decided ground in favor of the druggist being owner of the prescription. He cited a long legal opinion furnished by an experienced lawyer, Mr. R. C. McMurtrie, in support of his view.

"If the patient is the owner," says Mr. McMurtrie, "he may at any time within six years demand the paper, and if it is not surrendered, sue as for a tortious conversion of his property. If he can't do this he certainly has no title." Various instances are cited also showing the necessity to the druggist of owning and keeping the prescriptions.—*Med. Rec.*

JOHNSTOWN CORRESPONDENTS ASSOCIATION.

THE representatives of the great daily papers who worked in Johnstown during the days following the dreadful flood of May 31, 1889, have formed an organization known as the Johnstown Correspondent's Association. On the anniversary of the great disaster they meet and renew the friendships formed then, and recount the stirring scenes of those eventful months. This year they met in Johnstown and were delightfully entertained by the Cambria County Medical Society and the citizens generally. There were present representatives of the New York *World, Herald, Times* and *Mail and Express,* of the Philadelphia *Times, Record, Press, Inquirer* and *Public Ledger,* and of all the Pittsburgh papers. The entire party numbered about seventy-five persons. The different parties arrived in special cars on Saturday, May 30, and were at once taken in charge by a committee of citizens and by the following medical men: Drs. A. N. Wakefield, W. B. Towman, L. N. Mayer, G. W. Wagoner and E. S. Miller. The party were provided with carriages and driven to all the points of interest in the historic valley. The rooms of the Medical Society were used as the headquarters of the party and had been handsomely decorated for the purpose. An elegant lunch was served, during the entire day, in the rooms, and all enjoyed this feature of the entertainment very much. The members of the Medical Society turned out in full force and took special pride in receiving the guests at their rooms because they had a magnificent library to show them. The large and valuable collection of medical and literary works was recently given to the Society by Dr. Joseph M. Toner, of Washington, D. C. It comprises a large portion of a collection, to the acquirement of which this distinguished and learned gentleman has devoted his life and fortune, hence one can readily fancy how valuable it must be. There are nearly 5,000 titles, and among them are all the famous medical works of the last 150 years. Dr. Toner passed his boyhood days in Johnstown and entered upon the study of medicine many years ago, in the office of Dr. John Lowman, who was then, as he is now, one of the most distinguished practitioners of medicine and surgery in Western Pennsylvania. Dr. Toner has never forgotten the early home or his old preceptor, and now in his declining years he has manifested his affection by enriching the medical profession of the community where he first imbibed medical knowledge. The Toner Library contains many volumes which could not be duplicated. The members of the Medical Society are justly proud of the splendid library and the many other articles of interest and value which Dr. Toner has donated to their use, and took very great pleasure in exhibiting their possessions to the visitors. The Toner Library is the first public one established in the city since the flood and was therefore a centre of interest. It is well cared for in one of the principal business blocks of the new city. At the close of their day of sight-seeing the visiting reporters were given a banquet at a hotel, by the citizens, and left the city surprised at the wonderful progress it had made since the flood, and delighted at the elegant manner in which they had been entertained.

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co 's Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it, not only for its purity, but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M.D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

No Openers required. FOR USE IN SICK ROOMS and families. By a recent and most practicable invention no openers in future will be required for G. H. Mumm & Co.s Champagne.
To break the wire—bring the small seal to a horizontal position, and bend from side to side till one of the wires is broken, pulling upward removes top of cap and wire—done in an instant.

The 1884 vintage has been unexcelled in years, and Messrs. G. M. Mumm & Co. secured large quantities of it. Of the 1887 and 1889 vintages, worthy successors to the 1884, Messrs. G. M. Mumm & Co. also bought immense quantities, they making it a rule to lay in sufficient stock of fine vintages to tide over the poorer ones, which accounts for the uniformity and excellence of their justly celebrated Extra Dry, and enables them to supply all demands, while maintaining the same high character of their wine.

JOHN C. BAKER & CO.'S
STANDARD PREPARATIONS.

Messrs. JOHN C. BAKER & Co.

Gentlemen:

It affords me pleasure to have the opportunity of recommending your Cod Liver Oil to the medical profession. I feel satisfied that a purer and more efficacious article can not be obtained in the market.

Yours, with respect, JOSEPH LEIDY,

Professor of Anatomy in the University of Penna.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

Baker's Cod Liver Oil and Malt Extract.

SOLUTION FERROUS MALATE,
SOLUTION SALICYLATE IRON,
BARLETT'S PILE SUPPOSITORIES.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

OFFICE AND LABORATORY

815 FILBERT STREET,

PHILADELPHIA.

DR. GARRETSON'S work on the *Diseases and Surgery of the Mouth, Jaws, Face, Teeth and Associate Parts* is the only thorough treatise on the subject. So much new matter has been introduced in the *Fifth Edition*, recently issued, as to make it obligatory upon every dentist, who desires to keep abreast of the advance of thought, to add this standard work to his library. Price in Cloth Binding, $9.00. Sheep, $10.00.

DR. J. M. DACOSTA'S *Medical Diagnosis* furnishes some of the most entertaining medical reading to be found in our modern literature. So much of the text has been rewritten and so much of intrinsic value has been added to this new *Seventh Edition* that the practicing physician can not well afford to be without the work. In Cloth Binding, $6.00. Sheep Binding, $7.00.

For sale by all Booksellers, or, will be sent, free of expense, on receipt of the price.

Clinical Lecture.

DOUBLE OÖPHORECTOMY—SUPRA-VAGINAL HYSTERECTOMY.

BY WILLIAM GOODELL, M. D.,

PROFESSOR OF GYNÆCOLOGY, UNIVERSITY OF PENNSYLVANIA.

DOUBLE OÖPHORECTOMY.

Gentlemen:—The first case that I shall operate upon before you to-day, is that of a woman, forty years old, whose ovaries I shall remove. The history of her case is as follows: She has been married a good many years, and has born several children. For the past few years she has been constantly suffering with a dragging, gnawing pain in her left side, which has been steadily growing worse until now she is a constant sufferer, wholly unfit for any work—an invalid, in fact. Her pain is evidently of an ovarian origin, and my diagnosis is that the left ovary, which is much enlarged, is the one principally affected. At this woman's age, especially as her maternal instincts have already been gratified, we should feel no compunction in removing her ovaries, feeling confident—as we do in this case—that they, or at least one of them, is the cause of her present pitiable condition. These organs can no longer be of any material service to her, but are capable of doing infinite harm, and, perhaps, eventually causing the woman's death. You see she is emaciated, and shows unmistakable signs of years of suffering.

Before being brought into the clinic the patient's abdomen has been thoroughly washed and scrubbed and covered with an antiseptic bandage. This, we now remove, and again thoroughly wash the parts with a strong mercuric solution—1:1,000—and shave off the pubic hair, in order to render the field of our operation absolutely aseptic. Another point, which I have already drawn your attention to before now, is to keep your instruments immersed in water. Dust, or dirt, laden with infection, will not reach or adhere to submerged instruments. Finally, be most careful to count your instruments, and especially your hæmostatic forceps, both before and after the operation, writing their number down on paper and not trusting to your memory. This precaution, while apparently superfluous, is of great importance, since it renders the accidental leaving of a hæmostat or other instrument in the wound impossible.

I first make a superficial incision about four or five inches long and about midway between the umbilicus and symphysis pubis, down to the linea alba or uniting line of the sheaths of the recti muscles. Tearing the muscles apart, I come to the præperitoneal fat, and under it to the peritoneum. This membrane is caught up with a pair of dressing forceps, and nicked open. Taking good care beforehand to feel whether a loop of intestine is in the fold. The bleeding points in the skin and muscle are caught with hæmostatic forceps. Having now opened the peritoneum I am able to introduce my fingers into the abdominal cavity. I can now feel the womb and, following the course of the Fallopian tube, find the left ovary which is adherent, but not so firmly as to cause any great difficulty in loosening it. This is the ovary in which she has suffered so much pain. After firmly ligating the tube I proceed to remove it. I now bring out the right ovary. This is also adherent, but very slightly so. But now that I have removed it I see that it, as well as the left, is diseased. The condition of the ovaries before us is quite sufficient to account for the woman's sufferings during the past years, for they are much enlarged by cystic degeneration. You see that the removal of these ovaries has occupied only a few minutes. To be sure the case is a simple one; there has been no pus, and but few adhesions.

We shall now proceed to close the wound.

I first place a hot, wet, aseptic sponge in the wound over the intestines. Now I introduce deep silk sutures which include every layer of tissue. Next the linea alba are brought together by a continuous and buried gut suture. Before drawing up these sutures, and tying them, we remove the sponge which has been protecting the intestines. This row of buried gut sutures is most important and should never be neglected. Its value is in preventing subsequent hernia, and I have seen ugly looking hernias, even in very small incisions, resulting from a disregard of this proceedure. The deep silk sutures are now tied, and all that remains to be done is to apply the usual antiseptic dressing and binder. You see that the closing of the wound has occupied more time than the operation, but in operations of this kind every detail must be performed with equal exactness, in order to ensure subsequent successful results.

FIBROID TUMOR OF THE WOMB; SUPRA-VAGINAL HYSTERECTOMY.

The patient now before you is a woman, thirty-nine years old, and married, but has never born any children. For several years back she has had both menorrhagia and metrorrhagia, and now copious bleeding occurs every two weeks. These came from a large fibroid tumor of the womb. This long continued bleeding has greatly prostrated the patient, so that she is a confirmed invalid although very fat, as you see. The fat, however, is pale and flabby. Strange to say, bleeding in women very frequently acts as a fat producer, as it has done in this case.

What the operation will be, I cannot yet say. If I can get at the ovaries I shall remove them; if not, I shall have to remove the womb, making the operation a hysterectomy.

You see I make a much freer and bolder incision in this case than in the previous one, on account of the abundant fat. These fatty cases are always difficult to operate upon, and I, for one, do not like them. After cutting through this first thick layer of fat, we come to the tendenous sheath of the two recti muscles. Separating them, another layer of flabby fat is revealed which I also cut through, and with it the peritoneum. I find the omentum adherent to the abdominal wall. This is stripped off to get into the peritoneal cavity.

I now have my hand on a large fibroid tumor of the womb, and I cannot reach the ovaries. The case is a bad one—worse indeed than I at first expected. First of all we must enlarge this incision considerably in order to give ourselves more room, and to get the tumor out. The necessarily large incision is the principal objection to fat cases; but here the unusual size of the tumor would call for a large opening anyhow.

Notice how that the catch in the breathing of the patient throws the intestines forward and make them protrude from the wound. This is another unpleasant feature of the case.

I find the tumor adherent to the anterior wall of the abdomen, but think I can get it out. We are dealing with a large tumor of the womb, evidently a fibroid, and our opening is still too small to permit of its removal and I therefore enlarge it. Through the incision you may now get a glimpse of the growth. See these angry and tortuous veins running over its surface; some of them are as large, almost, as my index finger.

At last, by breaking up adhesions, I have succeeded in bringing one end of the tumor into the womb, you see it is as large as the head of an adult; but I am still unable to get at the tumor, which is very voluminous and has no neck. I must, therefore, again enlarge the wound. Dr. Taylor will now push up the womb *per vaginam*, so that I may be able to get a better idea of the limits of the growth. It is bound down by adhesions everywhere, and while I might now be able to forcibly bring it out into the wound, I dont like to break up adhesions that I cannot see or get at. This time, in enlarging the wound, I have cut through and far above the naval. By screwing a corkscrew into its upper portion I get a good strong purchase and deliver all but the pelvic portion out of the wound.

As it has no neck, the lower portion being as large as the upper, I shall have to enucleate it out of its uterine capsule, and convert the flaccid capsule into a nedicle. To do this safely I place two rubber tubes tightly around the lowest portion of the tumor, to arrest hæmorrhage. I use two rubber tubes as I care not to trust to one alone. Remember, that if during the course of enucleation these tubes should break, we should have a terrific hæmorrhage which could with difficulty be arrested, perhaps not soon enough to save the patient. Practically, therefore, the patient's life hangs upon the strength of these rubber tubes, and I therefore take the precaution of using two instead of one.

Let me now proceed to the enucleation, which I begin by making a circular incision

around the growth about 3 inches above the tube constrictors, and gradually dissect the capsul free from the tumor. This is difficult because, by inflammatory action, the tumor has cohered to the uterine walls. By the aid of knife and scissors the lower portion of the tumor, through very slow enucleation which is unusual, has decreased from about eight inches in diameter to about four, and when I have completed the enucleation, the pedicle will be only as large as my wrist. I then replace the rubber tubes with this wire ecraseur, which is kept from slipping off by two transfixing pins. The redundant portion of the stump is cut off.

I now close the abdominal wound, first by sewing, with gut, the peritoneal surface of the stump below the wire of the ecraseur to the peritoneal edges of the wound. Next, deep sutures are passed through all the different layers of the abdominal wall. Then the tendonous fascia divided at the linea alba is, as in the former operation, united by a continuous and buried gut suture. The deep silk sutures are now tied, and the wound dusted with iodoform and covered with corrosive sublimate gauze. To avoid putrefaction of the stump it is buried in boric acid. This has been a formidable operation, but the outlook is by no means a bad one.[1]

DIAGNOSIS OF VESICAL TUMORS.—HÆMATURIA AND ENDOSCOPIC EXAMINATION OF THE BLADDER.

BY DR. GUYON,

PROFESSOR OF CLINICAL SURGERY AT THE NECKER HOSPITAL, PARIS.

Gentlemen:—To-day I will operate on a case of vesical neoplasm, but before bringing the patient before you, I wish to give you some practical points regarding the diagnosis of vesical tumors, and in doing so, will pay particular attention to the subjects of hæmaturia, and the direct examination of the bladder by means of the endoscope.

The patient in question is a man 65 years old, who, for the last three months, has without an apparent cause, been suffering from hæmaturia. Nearly every time he urinates, he also passes more or less blood, both at the beginning and at the end of micturition. Sometimes his urine is clear, but then even it will usually deposit a few blood clots. Apart from this symptom, the patient's urinary organs are normal. Urination is neither abnormally frequent nor painful, and is always accomplished with ease, and especially so when the urine is free from blood, it is then clear, limpid, and free from sediment. Direct examination shows that the urethra is normal and that the bladder is not sensitive to moderate dilatation. The injected fluid will pass out of the catheter entirely clear, except the last few drops, which will be colored with blood. The quantity of the blood will be materially increased if the catheter is allowed to remain in the bladder for a few moments, before the expulsion of the liquid. The prostate, seminal ducts, and testicles are normal.

If, before resorting to an endoscopic examination, we make an examination by palpation, one finger being inserted into the rectum, and the other hand over the bladder, we will find an enlargement on the right side. This growth, if such an examination will warrant us calling it such, is neither hard nor clearly defined. The sensation experienced by palpation is, rather, as though this portion of the bladder was of a syrupy or gluey consistency. The patient's general condition is good, and an examination of the kidneys is negative.

This examination alone, is sufficient to warrant the assumption that we are here dealing with a versical neoplasm, but then among the diagnostic signs, that of hæmaturic is the most important.

In all such cases hæmaturia is always present. The urine will become bloody without any attributable reason; the patient has not been suffering either from any great exhaustion or from any traumatism; there is never any alteration in either the frequency or mode of urination, and the act is accompanied by no pain. In brief, to all appearances we are dealing with a healthy and absolutely normal bladder, with the exception of this one symptom—hæmaturia.

If such a hæmaturia has lasted for three months, accompanied by these characteristics, there is only one diagnosis for us to assume, viz., that of vesical neoplasm. In my opinion, a neoplasm will exist for some time before the appearance of the hæmaturia. This is the weak point in this important diagnostic symptom. For, if the hæmaturia set in as soon as the tumor began to develop, we might accomplish much by an early treatment. Unfortunately, however, the symptom may not appear until the growth has obtained considerable size. In fact, the appearance of this symptom has no connection to the size or growth of the tumor; it

[1] Two weeks later this patient was exhibited to the class. She had done extremely well, having had a temperature which reached 100° only on one day.

may appear comparatively early, or not until the growth has been present for some time.

One might reasonably suppose that the amount of the hæmorrhage depended upon the size of the tumor, but unfortunately this is not the case, and the diagnostician is liable to fall into grave error if he gauges the size of the tumor by the extent of the hæmorrhages. A small tumor will not infrequently give rise to enormous hæmorrhages, so severe, indeed, as to materially effect the general health of the patient, while, on the other hand, tumors of a very large size will only occasion trifling hæmorrhages; but, as you see, that the size of these hæmorrhages have nothing to do with the volume of the tumor, it is quite different regarding their frequency. The hæmorrhages due to neoplasms are always frequently recurring.

It has been said, and I have said it myself, that vesical tumors sometimes exist without causing any hæmaturia. I believe, however, that on this point it will be well to make one observation, viz.: that in order to be positive of the absence of this symptom, a most careful examination of the urine is necessary. Let me cite a case.

About two weeks ago, I operated upon a case of enormous vesical tumor, so large indeed that the operation only resulted in being a palliative. The patient, however, had had apparently no hæmaturia. He claimed never to have passed blood to his knowledge. The urine, upon superficial examination seemed clear and limpid enough but a closer examination revealed the existence of several minute clots at the bottom of the vessel. Without doubt, these would have been overlooked by many, and the case declared to be one of vesical tumor without hæmaturia.

While the quantity of the hæmorrhage is entirely independant of the size of the tumor, it is, however, of considerable diagnostic value in determining the nature of the growth. Certain hard carcinomatous growths found in the bladder do not bleed, while epitheliomæ bleed easily.

If the hæmaturia is insufficient to allow an accurate diagnosis, we must use other means in determining the nature of the growth, viz.: direct examination of the bladder by means of the endoscope. In the case which serves as the object of this lesson, it is very probable that an examination of the bladder one year ago would have confirmed a diagnosis of vesical tumor, and, in that case, the operation could have been promptly performed and the patient's chances would have been far more favorable than they are now. It would, however, have been necessary for the patient to consider himself ill enough at the time to need medical advice, which was not the case. But even if he had come to a surgeon, there would have been no symptom which could have warranted an examination of the bladder by means of the endoscope.

The symptom of hæmaturia appears too late to assist in the diagnosis of the disease at its outset, and at the same time, it is the first symptom that we have to indicate the presence of any abnormality. The result is, that the endoscope is rarely, if ever, the means of the primary diagnosis of vesical tumors.

But may not the endoscope confirm an uncertain diagnosis? Certainly, yes. It will tell the surgeon whether he is dealing with a small tumor, surcharged with blood, or with a large growth. By its aid we can also frequently confirm the nature of the tumor; whether epithelial, or a papilloma, or benign. Very frequently a simple variety of epithelioma is met with and unfortunately the endoscope is for many reasons rarely of any practical value in these cases.

Even if a bladder is sensitive and will not permit of an endoscopic examination on account of the pain produced, its inflation with a liquid will frequently enable the direct examination to be made. But these conditions are often only intensified in patients suffering from vesical tumors. With these even chloroform sometimes fails to allow the bladder to be distended sufficiently to permit of an examination with the endoscope.

In the patient before us, and upon whom I am about to operate, distention of the bladder was accompanied with ease. But we here have another trouble confronting us. We counted on the urine in the bladder being clear, and not disturbing the transparency; but on the contrary, so soon as we introduced our endoscope into the distended bladder, we found the instrument surrounded by an opaque liquid, which rendered the attempt at an endoscopic dilation unfruitful. To remedy this we endeavored to keep a continual stream of water running through the bladder, but this did not sufficiently clear its contents to enable us to get any view of the tumor.

Another frequent difficulty attending the successful use of the endoscope, is the size of the tumor. If by the endoscope we cannot get a view of the limits of the growth, the examin-

ation will accomplish but little more than palpation. In short, the value of the endoscope as a diagnostic means in cases of vesical tumors at least, has been much overrated. Nevertheless, in cases of small growths, when it is possible to clean the contents of the bladder, so as to obtain an unobstructed view, the instruments may often be of great service. Its use will also tell the operator whether he is dealing with an old or recent growth.

So, you see, that while the endoscope may be applicable for the examination of vesical tumors, it does not fulfil all the requirements that one might *a priori* suppose it to do. It is perhaps well for me thus to draw your attention to its weak points, in order that you may be guarded against the exaggerated enthusiasm of many eminent genito-urinary surgeons. Still, in cases where its successful employment is possible, it is undoubtedly of very great value to the diagnostician. It is a great mistake to imagine for a moment that an endoscopic is called for in every case of vesical disease, but it is an equally bad a blunder to dispense entirely with its use. It was for this reason that I attempted such an examination in the patient before you, but unfortunately with negative results. We will now proceed to the operation itself.

While the diagnosis of vesical tumor is confirmed, I am largely ignorant of either the size or nature of the growth, and therefore must run the risk of finding a very extensive disease, perhaps infinitely worse than the general symptoms would indicate. Do not forget, however, that in this case we have no history of abundant hæmorrhages, but on the contrary, the bleeding has only been slight, but it has occurred every day. Yet such operations are frequently attended by severe hæmorrhages. In one of such, I have seen an anæmic patient die on the table. In these bleeding tumors the ultimate success of the operation is also greatly jeapardized. That we have here a tumor which bleeds easily has been shown by the fact that we have been unable to free the bladder sufficiently from blood to enable us to make an endoscopic examination.

An operation having been decided upon, a final question arises, and this is, the possibility of a recurrence of the disease. Without doubt, in this case, where the indications are towards a vesical cancer, recurrence is probable, but the operation will, more the less, be of great value to the patient. I could quote you the histories of a number of similiar cases upon which I have operated, and the results, while perhaps only temporary, are nearly always encouraging and satisfactory to the patient. At present the tumor is increasing in size, already his general health is beginning to suffer, and the hæmaturia is a constant drain upon his system. I will endeavor to remove the entire growth, if possible, and in all probability the man will be able to return to his work, and his health will greatly improve. A case I operated upon in September 1889,—a very aggravated case—is now doing well, and apparently in excellent health.

The patient before the class was then operated upon. The case was found to be one of cancer. The growth was removed by means of the galvano-cantery and the currette. The patient made a rapid and excellent recovery from the operation.—Translated from *Le Bulletin Médical.*

COMMUNICATIONS.

STRYCHNIA AS A HEART STIMULANT IN PNEUMONIA.

BY J. J. THOMAS, M. D.,
YOUNGSTOWN, OHIO.

In *St. Bartholomew's Hospital Reports,* vol. xxii, there is to be found a paper by S. Herbert Habershon, M. B., on the use of strychnia by hypodermic injections in heart failure, particularly that of pneumonia. THE REPORTER of Dec. 10th, 1887 contains an editorial upon the paper in question. Habershon places strychnia in the front rank as a cardiac tonic and claims to have seen from its use better and more lasting effects than from ether, ammonia or alcohol. Digitalis even, he considers to be secondary in value to strychnia in all cases of exhausted heart muscles, particularly in cases of disease of the mitral and aortic valves and in pneumonia with Cheyne-Stokes respiration and marked cyanosis. He advocates the use of the drug hypodermically and in larger than ordinary doses, citing cases which appear strongly to support the conclusions of his views. The matter made a more than passing impression upon the mind of the writer, and it was determined to give this use of strychnia a trial in every appropiate case occurring during a period of sufficient duration to make any deduction one of value.

Several years have passed by since the publication of Dr. Habershon's paper and

numerous opportunities have been afforded me of putting his views to the test. My observations have been made chiefly upon cases of pneumonia, giving the remedy hypodermically in all cases of unusual severity, especially where heart failure threatened. I have kept no record of cases for publication, but while penning these lines my mind reverts to occasions whereupon the hypodermic administration of $\frac{1}{25}$ gr. doses of sulphate of strychnia, repeated every six hours, certainly appeared to act with wondrously tonic effect upon the o'erwrought and jaded heart, turning favorably the tide of life in seemingly hopeless cases.

Recent studies of the *modus operandi* of heart stimulants and tonics appears to support the validity of the claims made by Habershon in favor of the value of strychnia.

The Harveian oration of Dr. James Andrews of St. Bartholomew's, delivered Oct. 18, 1890, consists largely of a critical comparison of the actions of this class of remedies in question upon the pulmonary and systemic circulations. It is shown that strychnia "produces, in both carotid and pulmonary arteries, a rise in pressure, *especially marked in the pulmonary artery.*" In this particular respect the drug compares very favorably with the best, ordinarily and heretofore commonly resorted to in threatening heart failure.

It is universally conceded that heart exhaustion is a common and direct cause of death in pneumonia, and however practitioners may differ as to the use or non-use of venesection in the early stages of that disorder there is none to dispute the propriety and the necessity, in many cases, of applying to the flagging heart the whips and the spur ere the crisis is reached.

Dr. Andrew H. Smith has contributed to the *American Journal of the Medical Sciences* an extremely valuable article on "Acute Obstructive Diseases of the Lungs," in which he calls renewed attention to the fact that it is the *right* heart that bears the chief burden in pneumonia; though he makes no mention of the peculiar properties of strychnia in furnishing to that particular side the needed stimulus. He emphasizes the importance of making a daily study of the pulmonary circulation by observation of the pulmonary valve sound.

Dr. Bradford, in the *New York Medical Journal*, of Jan. 10, 1891, compares the the actions of digitalis and strychnia, his article being at once elaborate and scientific. He prefers the latter in conditions of enfeebled heart muscle, for the reason that its action is indirect, being expended chiefly and primarily upon the spinal cord and sympathetic system. It imparts tone to the functions of the entire muscular system and is a tonic in the truest sense of the term. He reports cases of collapse restored by strychnia given freely, and urges its use, particularly in pneumonia and diphtheria.

It is altogether probable that to some, if not to a marked extent, strychnia acts directly upon the muscles of the right side of the heart and in the same manner that digitalis acts. This with its wider influence in imparting a better nervous tone makes it the ideal heart stimulant in pneumonia. In critical cases I give it in doses of $\frac{1}{25}$ gr. every 4 or 6 hours, and can ask no better illustration of the resources of therapeutics than that afforded by the quick response which almost invariably follows. Hypodermically appears to be the best mode of administration. Whatever may be the *rationale* of its operation, I have, within the last few years, witnessed too many illustrations of the value of this article to be at all hesitant in pronouncing it an invaluable resource in pneumonia, and one that will often and often be found to justify the confidence reposed in it. A tolerance of the drug appears to obtain in pneumonia, and to secure good effects the dosage must be decided and frequent.

THREE CASES OF HYSTERO-EPILEPSY.

BY H. F. BYERS, M. D.,
CARUTHERSVILLE, MISSOURI.

On June 26, 1889, I was called to attend Mrs. H. B., a married lady, 26 years of age, the mother of two children. On my arrival the lady was found lying dressed upon the side of the bed engaged in conversation with several neighbors. Her husband stated that she had had several very hard "fits" with no preceding or apparent cause whatever, her health was usually excellent, but that on several previous occasions she had had "spells" of greater or less severity, the first happening shortly after the birth of her elder child, some four years ago. The thermometer was placed in the axilla and showed a temperature of 99° F. The pulse was normal, skin moist and natural, bowels constipated. She answered readily and intelligently all questions, and complained of hot flashes and various pains. When asked to describe any symptoms that advised her of the approach of a spasm, she said that they always came

on with a violent sense of cramping and a drawing in of the big toe of the right foot, and that something seemed to rise from that point and choke her. While engaged in conversation with her she suddenly exclaimed: "There, doctor, one is coming on now." The big toe of the right foot, of course, claimed my immediate attention, it was found to be forcibly flexed, while the foot was extended to the utmost, in rapid succession all the muscles of the right limb, and then of the whole body, became involved in tonic convulsions. The head was thrown back and to the left, the eyes rolled back so that the whites alone were visible, and there followed a convulsion in all respects, save only one, like those of puerperal eclampsia—the tongue was not bitten. Two more convulsions occurred in rapid succession, when they were controlled by the hypodermatic injection of morphiæ sulphatis gr. $\frac{1}{4}$, and atrophiæ sulphatis gr. $\frac{1}{150}$. A prescription of potass. bromidi gr. xx, chloral hydrat, gr. x, morphiæ sulph. gr. $\frac{1}{8}$, to be given at intervals varying from one to four hours, p. r. n., controlled the spasms for twenty-four hours, when the hypodermatic injection was repeated, with only temporary relief. After exhausting my therapeutical resources, and a considerable amount of patience, and being out of the reach of consultation, I gave, with a view of its relaxing effect, as well as the mental impression, 2 grains of the yellow sub-sulphate or mercury and a pint of warm water. The lady began in about fifteen minutes to alarm her husband and friends by assuring them that "death had struck her," and by giving directions as to the disposition to be made of her effects. This was followed by copious emesis and immediate permanent relief, so far as the "fits" were concerned. This lady is in robust health and had had no return of the convulsions in almost two years, and so far as is known to the writer, no other manifestations of hysteria.
